CRAMP. (From *krempen*, to contract. Germ.) See *Spasm.*

CRANESBILL. See *Geranium.*

Cranesbill, bloody. See *Geranium sanguineum.*

CRA'NIUM. (Κρανιον, *quasi* καρανιον; from καρα, the head.) The skull or superior part of the head. See *Caput.*

Crante'res. (From κραινω, to perform.) A name given to the dentes sapientiæ and other molares, from their office of masticating the food.

CRA'PULA. (Κραιπυλα.) A surfeit; drunkenness.

CRA'SIS. (From κεραννῦμι, to mix.) Mixture. A term applied to the humours of the body, when there is such an admixture of their principles as to constitute a healthy state: hence, in dropsies, scurvy, &c. the crasis, or healthy mixture of the principles of the blood, is said to be destroyed.

Cra'spedon. (Κρασπεδον, the hem of a garment; from κρεμαω, to hang down, and πεδον, the ground.) A relaxation of the uvula, when it hangs down in a thin, long membrane, like the hem of a garment.

CRASSAME'NTUM. (From *crassus*, thick.) See *Blood.*

CRA'SSULA. (From *crassus*, thick: so named from the thickness of its leaves.) See *Sedum telephium.*

CRATÆ'GUS. (From κρατος, strength: so called from the strength and hardness of its wood.) The wild service-tree, of which there are many, are all species of the genus *Prunus.* The fruits are most of them astringent.

CRATEVA. (So called from Cratevas, a Greek physician, celebrated by Hippocrates for his knowledge of plants.) The name of a genus of plants. Class, *Polyandria;* Order, *Monogynia.*

Crateva marmelos. The fruit is astringent whilst unripe; but when ripe of a delicious taste. The bark of the tree strengthens the stomach, and relieves hypochrondriac languors.

Crati'cula. (From *crates*, a hurdle.) The bars or grate which covers the ash-hole in a chemical furnace.

CRATON, John, called also **Crafftheim,** was born at Breslaw in 1519. He was intended for the church, but preferring the study of medicine, went to graduate at Padua, and then settled at Breslaw. But after a few years he was called to Vienna, and made physician and aulic counsellor to the Emperor Ferdinand I.; which offices also he held under the two succeeding emperors, and died in 1585. His works were numerous: the principal are, "A Commentary on Syphilis;" "A Treatise on Contagious Fever;" another on "Therapeutics;" and seven volumes of Epistles and Consultations.

Cream of tartar. See *Potassæ supertartras.*

CREMA'STER. (From κρεμαω, to suspend.) A muscle of the testicle, by which it is suspended, and drawn up and compressed, in the act of coition. It arises from Poupart's ligament, passes over the spermatic chord, and is lost in the cellular membrane of the scrotum, covering the testicles.

Cre'mnus. (From κρημνος, a precipice, or shelving place.) 1. The lip of an ulcer.

2. The labium pudendi.

CRE'MOR. 1. Cream. The oily part of milk which rises to the surface of that liquid, mixed with a little curd and serum. When churned, butter is obtained. See *Milk.*

2. Any substance floating on the top, and skimmed off.

CRENATUS. Crenate or notched, applied to a leaf or petal, when the indentations are blunted or rounded, and not directed towards either end of the leaf: as in *Glecoma hederacea.* The two British species of *Salvia* are examples of doubly crenate leaves. The petals of the *Linum usitatissimum* are crenate.

CRE'PITUS. (From *crepo*, to make a noise.) A puff or little noise. The word is generally employed to express the pathognomonic symptoms of air being collected in the cellular membrane of the body; for when air is in these cavities, and the part is pressed, a little cracking noise, or crepitus, is heard.

Crepitus lupi. See *Lycoperdon bovista.*

Crescent-shaped. See *Leaf.*

CRESS. There are several kinds of cresses eaten at the table, and used medicinally, as antiscorbutics.

Cress, water. See *Sisymbrium nasturtium aquaticum.*

CRE'TA. Chalk. An impure carbonate of lime. See *Creta præparata.*

Creta præparata. Take of chalk a pound; add a little water, and rub it to a fine powder. Throw this into a large vessel full of water; then shake them, and after a little while pour the still turbid liquor into another vessel, and set it by that the powder may subside; lastly, pouring off the water, dry this powder. Prepared chalk is absorbent, and possesses antacid qualities: it is exhibited in form of electuary, mixture, or bolus, in pyrosis, cardialgia, diarrhœa, acidities of the primæ viæ, rachitis, crusta lactea, &c. and is said by some to be an antidote against white arsenic.

Cretaceous acid. See *Carbonic acid.*

Crete, dittany of. See *Origanum dictamnus.*

CRETINISMUS. Cretinism. A species of *Cyrtosis* in Dr. Good's Nosology: a disease affecting chiefly the head and neck; countenance vacant and stupid; mental faculties feeble, or idiotic; sensibility obtuse, mostly with enlargement of the thyroid gland.

CRIBRIFO'RM. (*Cribriformis;* from *cribrum*, a seive, and *forma*, likeness; because it is perforated like a seive.) Perforated like a seive. See *Ethmoid bone.*

CRICHTONITE. A mineral named after Dr. Crichton, which Jameson thinks is a new species of titanium ore. It is of a splendent velvet black colour.

CRI'CO. Names compounded of this word belong to muscles which are attached to the cricoid cartilage.

Crico-arytænoideus lateralis. *Crico-lateri arithenoidien* of Dumas. A muscle of the glottis, that opens the *rima* by pulling the ligaments from each other.

Crico-arytænoideus posticus. *Crico creti arithenoidien* of Dumas. A muscle of the glottis, that opens the *rima glottidis* a little, and by pulling back the arytænoid cartilage, stretches the ligament so as to make it tense.

Crico-pharyngeus. See *Constrictor pharyngis inferior.*

Crico-thyroideus. *Crico-thyroidien* of Dumas. The last of the second layer of muscles between the os hyoides and trunk, that pulls forwards and depresses the thyroid cartilage, or elevates and draws backwards the cricoid cartilage.

CRICOI′D. (*Cricoides*; from κρικος, a ring, and ειδος, resemblance.) A round ring-like cartilage of the larynx is called the cricoid. See *Larynx*.

CRIMNO′DES. (From κριμνον, bran.) A term applied to urine, which deposits a sediment like bran.

Crina′tus. (From κρινον, the lily.) A term given to a suffumigation mentioned by P. Ægineta, composed chiefly of the roots of lilies.

CRI′NIS. The hair. See *Capillus*.

Crinomy′ron. (From κρινον, a lily, and μυρον, ointment.) An ointment composed chiefly of lilies.

CRINONES. (From *crinis*, the hair.) *Malis gordii* of Good. *Morbus pilaris* of Horst. *Malis à crinonibus* of Elmuller and Sauvages. Collections of a sebaceous fluid in the cutaneous follicles upon the face and breast, which appear like black spots, and when pressed out, look like small worms, or, as they are commonly called, maggots.

Crio′genes. An epithet for certain troches, mentioned by P. Ægineta, and which he commends for cleansing ulcers.

CRIPSO′RCHIS. (From κρυπτω, to conceal, and ορχις, a testicle.) Having the testicle concealed, or not yet descended from the abdomen, into the scrotum.

CRI′SIS. (From κρινω, to judge.) The judgment. The change of symptoms in acute diseases, from which the recovery or death is prognosticated or judged of.

Crispatu′ra. (From *crispo*, to curl.) A spasmodic contraction or curling of the membranes and fibres.

CRISPUS. Curled. Applied to a leaf, when the border is so much more dilated than the disk, that it necessarily becomes curled and twisted; as in *Malva crispa*, &c.

CRI′STA. (*Quasi cerista*; from κερας, a horn, or *carista*; from καρα, the head, as being on the top of the head.) Any thing which has the appearance of a crest, or the comb upon the head of a cock. 1. In anatomy it is thus applied to a process of the ethmoid bone, *christa galli*, and to a part of the *nymphæ*;—*crista clitoridis*.

2. In surgery, to excrescences, like the comb of a cock, about the anus.

3. In botany, to several accessary parts or appendages, chiefly belonging to the antheræ of plants; as the pod of the *Hedysarum crista galli*, &c.

Crista galli. An eminence of the ethmoid bone, so called from its resemblance to a cock's comb. See *Ethmoid bone*.

CRISTATUS. Crested. Applied to several parts of plants.

Cri′thamum. See *Crithmum*.

Cri′the. (Κριθη, barley.) A stye or tumour on the eyelid, in the shape and of the size of a barley-corn.

Crithe′rion. (From κρινω, to judge.) The same as crisis.

CRI′THMUM. (From κρινω, to secrete; so named from its supposed virtues in promoting a discharge of the urine and menses.) Samphire or sea-fennel.

Crithmum maritimum. The Linnæan name of the samphire or sea-fennel. *Crithmum* of the pharmacopœias. It is a low perennial plant, and grows about the sea-coast in several parts of the island. It has a spicy aromatic flavour, which induces the common people to use it as a pot-herb. Pickled with vinegar and spice, it makes a wholesome and elegant condiment, which is in much esteem.

CRITHO′DES. (From κριθη, barley, and ειδος, resemblance.) Resembling a barley-corn. It is applied to small protuberances.

CRI′TICAL. (*Criticus*; from *crisis*; from κεινω, to judge.) Determining the event of a disease. Many physicians have been of opinion, that there is something in the nature of fevers which generally determines them to be of a certain duration; and, therefore, that their terminations, whether salutary or fatal, happen at certain periods of the disease, rather than at others. These periods, which were carefully marked by Hippocrates, are called *critical days*. The critical days, or those on which we suppose the termination of continued fevers especially to happen, are the third, fifth, seventh, ninth, eleventh, fourteenth, seventeenth, and twentieth.

CROCIDI′XIS. (From κροκιδιξω, to gather wool.) Floccilation. A fatal symptom in some diseases, where the patient gathers up the bedclothes, and seems to pick up substances from them.

Cro′cinum. (From κροκος, saffron.) A mixture of oil, myrrh, and saffron.

Croco′des. (From κροκος, saffron; so called from the quantity of saffron they contain.) A name of some old troches.

Crocoma′gma. (From κροκος, saffron, and μαγμα, the thick oil or dregs.) A troch made of oil of saffron and spices.

CRO′CUS. (Κροκος of Theophrastus. The story of the young Crocus, turned into this flower, may be seen in the fourth book of Ovid's Metamorphoses. Some derive this name from κροκη, or κροκις, a thread; whence the stamens of flowers are called κροκιδες. Others, again, derive it from *Coriscus*, a city and mountain of Cilicia, and others from *crokin*, Chald.) Saffron.

1. The name of a genus of plants in the Linnæan system. Class, *Triandria*; Order, *Monogynia*. Saffron.

2. The pharmacopœial name of the prepared stigmata of the saffron plant. See *Crocus sativus*.

3. A term given by the older chemists to several preparations of metallic substances, from their resemblance: thus, *Crocus martis*, *Crocus veneris*.

Crocus antimonii. A sulphuretted oxide of antimony.

Crocus germanicus. See *Carthamus*.

Crocus indicus. See *Curcuma*.

Crocus martis. Burnt green vitriol.

Crocus metallorum. A sulphuretted oxide of antimony.

Crocus officinalis. See *Crocus sativus*.

Crocus saracenicus. See *Carthamus*.

Crocus sativus. The systematic name of the saffron plant. *Crocus:—spatha univalvi radicali, corollæ tubo longissimo*, of Linnæus. Saffron has a powerful, penetrating, diffusive smell, and a warm, pungent, bitterish taste. Many virtues were formerly attributed to this medicine, but little confidence is now placed in it. The Edinburgh College directs a tincture, and that of London a syrup of this drug.

Crocus veneris. Copper calcined to a red powder.

Cro′mmyon. (Παρα το τας κορας μυειν, because it makes the eyes wink.) An onion.

CROMMYOXYRE′GMA. (From κρόμμυον, an onion, οξυς, acid, and ρηγνυμι, to break out.) An acid eructation accompanied with a taste resembling onions.

CROONE, WILLIAM, was born in London, where he settled as a physician, after studying at Cambridge. In 1659 he was chosen rhetoric professor of Gresham College, and soon after register of the Royal Society, which then assembled there. In 1662 he was created doctor in medicine by mandate of the king, and the same year elected fellow of the Royal Society, and of the College of Physicians. In 1670 he was appointed lecturer on anatomy to the Company of Surgeons. On his death, in 1684, he bequeathed them 100*l.*; his books on Medicine to the College of Physicians, as also the profits of a house, for Lectures, to be read annually, on Muscular Motion; and donations to seven of the colleges at Cambridge, to found Mathematical Lectures. He left several papers on philosophical subjects, but his only publication was a small tract, "De Ratione Motus Musculorum."

CROSS-STONE. Harmotome; Pyramidal zeolite. A crystallised greyish-white mineral, harder than fluor-spar, but not so hard as apatite, found only in mineral veins and agate balls in the Hartz, Norway, and Scotland.

CROTALUS. The name of a genus of reptiles.

CROTALUS HORRIDUS. The rattle-snake; the stone out of the head of which is erroneously said to be an antidote to the poison of venemous animals. A name also of the Cobra de capella, the *Coluber naja* of Linnæus.

CROTA′PHICA ARTERIA. The tendon of the temporal muscle.

CROTAPHI′TES. (From κροταφος, the temple.) See *Temporalis.*

CROTA′PHIUM. (From κροτεω, to pulsate; so named from the pulsation which in the temples is eminently discernible.) *Crotaphos. Crotaphus.* A pain in the temples.

CRO′TAPHOS. See *Crotaphium.*

CRO′TAPHUS. See *Crotaphium.*

CROTCHET. A curved instrument with a sharp hook to extract the fœtus.

CRO′TON. (From κροτεω, to beat.)

1. An insect called a tick, from the noise it makes by beating its head against wood.

2. A name of the ricinus or castor-oil-berry, from its likeness to a tick.

3. The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Monadelphia.*

CROTON BENZOE. See *Styrax benzoe.*

CROTON CASCARILLA. The systematic name of the plant which affords the Cascarilla bark. *Cascarilla; Chocarilla; Elutheria; Eluteria.* The bark comes to us in quills, covered upon the outside with a rough, whitish matter, and brownish on the inner side, exhibiting, when broken, a smooth, close, blackish-brown surface. It has a light agreeable smell, and a moderately bitter taste, accompanied with a considerable aromatic warmth. It is a very excellent tonic, adstringent, and stomachic, and is deserving of a more general use than it has hitherto met with.

CROTON LACCIFERUM. The systematic name of the plant upon which gum-lac is deposited. See *Lacca.*

CROTON TIGLIUM. The systematic name of the tree which affords the pavana wood, and tiglia seeds. *Croton—foliis ovatis glabris acuminatis serratis, caule arboreo* of Linnæus.

1. Pavana wood. *Lignum pavanæ; Lignum pavanum; Lignum moluccense.* The wood is of a light spongy texture, white within, but covered with a greyish bark: and possesses a pungent, caustic taste, and a disagreeable smell. It is said to be useful as a purgative in hydropical complants.

2. *Grana tiglia. Grana tilli. Grana tiglii.* The grana tiglia are seeds of a dark-grey colour, in shape very like the seeds of the *ricinus communis.* They abound with an oil which is far more purgative than castor-oil, which has been lately imported from the East Indies, where it has been long used, and is now admitted into the London pharmacopœia. One drop proves a drastic purge, but it may be so managed as to become a valuable addition to the materia medica.

CROTON TINCTORIUM. The systematic name of the lacmus plant. *Croton—foliis rhombeis repandis, capsulis pendulis, caule herbaceo,* of Linnæus. *Bezetta cœrulea.* This plant yields the *Succus heliotropii; Lacmus seu tornæ; Lacca cœrulea; Litmus.* It is much used by chemists as a test.

CROTO′NE. (From κροτον, the tick.) A fungus on trees produced by an insect like a tick; and by metaphor applied to tumours and small fungous excrescences on the periosteum.

CROTOPHUS. (From κροτος, *pulsus.*) Painful pulsation.

CROTOPHIUM. (From κροτος, the pulse.) Painful pulsation.

CROUP. See *Cynanche.*

CROUSIS. (From κρουω, to beat, or pulsate.) Pulsation.

CROU′SMATA. (From κρουω, to pulsate.) Rheums or defluxions from the head.

CROWFOOT. See *Ranunculus.*

Crowfoot-cranesbill. See *Geranium pratense.*

CRUCIAL. (*Crucialis;* from *crus,* the leg.) 1. Cross-like. Some parts of the body are so called when they cross one another, as the crucial ligaments of the thigh.

2. A name of the mugweed or crosswort.

CRUCIA′LIS. See *Crucial.*

CRUCIBLE. (*Crucibulum;* from *crucio,* to torment: so named, because, in the language of old chemists, metals are tormented in it, and tortured, to yield up their powers and virtues.) A chemical vessel made mostly of earth to bear the greatest heat. They are of various shapes and composition.

CRUCIFORMIS. Cross-like. Applied to leaves, flowers, &c. which have that shape.

CRU′DITAS. (From *crudus,* raw.) It is applied to undigested substances in the stomach, and formerly to humours in the body unprepared for concoction.

CRUICKSHANK, WILLIAM, was born at Edinburgh, in 1746. He was intended for the church, and made great proficiency in classical learning; but, showing a partiality to medicine, he was placed with a surgeon at Glasgow. In 1771, he came to London, and was soon after made librarian to Dr. William Hunter; and, on the secession of Mr. Hewson, became assistant, and then joint lecturer in anatomy, with the Doctor. He contributed largely to enrich the Museum, particularly by his curious injections of the lympathic vessels. He published, in 1786, a work on this subject, which is highly valued for its correctness. In 1795, he communicated to the Royal Society an Account of the Regeneration of the Nerves; and the same year published a pamphlet on Insensible Perspiration; and in 1797, an Account of Appearances in the Ovaria of Rabbits in different Stages of Pregnancy. He died in 1800.

CRU′NION. (From κρουνος, a torrent.) A medicine mentioned by Aëtius, and named from the violence of its operation as a diuretic.

CRU'OR. (From κρυος, *frigus*, it being that which appears like a coagulum as the blood cools.) The red part of the blood. See *Blood*.

CRU'RA. The plural of *crus*.

Crura clitoridis. See *Clitoris*.

Crura medullæ oblongatæ. The roots of the medulla oblongata.

CRURÆ'US. (From *crus*, a leg; so named, because it covers almost the whole foreside of the upper part of the leg or thigh.) *Cruralis*. A muscle of the leg, situated on the fore-part of the thigh. It arises, fleshy, from between the two trochanters of the os femoris, but nearer the lesser, firmly adhering to most of the fore-part of the os femoris; and is inserted, tendinous, into the upper part of the patella, behind the rectus. Its use is to assist the vasti and rectus muscles in the extension of the leg.

CRURAL. (*Cruralis;* from crus, the leg.) Belonging to the crus, leg, or lower extremity.

Crural hernia. See *Hernia cruralis.*

CRURA'LIS. See *Cruræus.*

CRUS. 1. The leg.

2. The root or origin of some parts of the body, from their resemblance to a leg or root; as *Crura cerebri*, *Crura cerebelli; Crura* of the diaphragm, &c.

CRU'STA. 1. A shell.

2. A scab.

3. The scum or surface of a fluid.

Crusta lactea. A disease that mostly attacks some part of the face of infants at the breast. It is known by an eruption of broad pustules, full of a glutinous liquor, which form white scabs when they are ruptured. It is cured by mineral alteratives.

Crusta villosa. The inner coat of the stomach and intestines has been so called.

Crustula. (Dim. of *crusta*, a shell.) A discoloration of the flesh from a bruise, where the skin is entire, and covers it over like a shell.

Crustumina'tum. (From *Crustuminum*, a town where they grew.) 1. A kind of Catharine pear.

2. A rob or electuary made of this pear and apples boiled up with honey.

Crymo'des. (From κρυος, cold.) An epithet for a fever, wherein the external parts are cold.

CRYOLITE. A white or yellowish brown mineral, composed of alumina, soda, and fluoric acid. It is curious and rare, and found hitherto only at West Greenland.

CRYOPHORUS. (From κρυος, cold, and φερω, to bear.) The frost-bearer, or carrier of cold; an elegant instrument invented by Dr. Wollaston, to demonstrate the relation between evaporation at low temperatures, and the production of cold.

CRYPSO'RCHIS. (From κρυπτω, to conceal, and ορχις, a testicle.) A term applied to a man whose testicles are hid in the belly, or have not descended into the scrotum.

CRY'PTA. (From κρυπτω, to hide.) The little rounded appearances at the end of the small arteries of the cortical substance of the kidneys, that appear as if formed by the artery being convoluted upon itself.

CRYPTOGAMIA. (From κρυπτω, to conceal, and γαμος, a marriage.) The twenty-fourth and last class of the sexual or Linnæan system of plants, containing several numerous genera, in which the parts essential to their fructification have not been sufficiently ascertained to admit of their being referred to the other class. It is divided by Linnæus into four orders, *Filices*, *Musci*, *Algæ*, and *Fungi*.

Cryso'rchis. Κρυσορχις. 1. A retraction or retrocession of one of the testicles.

2. See *Crypsorchis.*

CRYSTAL. See *Crystallus.*

CRYSTALLINE. (*Crystallinus;* from its crystal-like appearance.) Crystal-like.

Crystalline lens. A lentiform pellucid part of the eye, enclosed in a membranous capsule, called the capsule of the crystalline lens, and situated in a peculiar depression in the anterior part of the vitreous humour. Its use is to transmit and refract the rays of light. See *Eye.*

Crystalli'num. (From κρυϛαλλος, a crystal: so called from its transparency.) White arsenic.

CRYSTALLISATION. (*Crystallizatio:* from *crystallus*, a crystal.) A property by which crystallisable bodies tend to assume a regular form, when placed in circumstances favourable to that particular disposition of their particles. Almost all minerals possess this property, but it is most eminent in saline substances. The circumstances which are favourable to the crystallisation of salts, and without which it cannot take place, are two: 1. Their particles must be divided and separated by a fluid, in order that the corresponding faces of those particles may meet and unite. 2. In order that this union may take place, the fluid which separates the integrant parts of the salt must be gradually carried off, so that it may no longer divide them.

CRYSTA'LLUS. *Crystallus, i. m.;* from κρυος, cold, and ϛελλω, to contract: *i. e.* contracted by cold into ice.) 1. A crystal. "When fluid substances are suffered to pass with adequate slowness to the solid state, the attractive forces frequently arrange their ultimate particles, so as to form regular polyhedral figures or geometrical solids, to which the name of crystals has been given. Most of the solids which compose the mineral crust of the earth are found in the crystallised state. Thus granite consists of crystals of quartz, felspar, and mica. Even mountain masses like clay-slate, have a regular tabulated form. Perfect mobility among the corpuscles is essential to crystallisation. The chemist produces it either by igneous fusion, or by solution in a liquid. When the temperature is slowly lowered in the former case, or the liquid slowly abstracted by evaporation in the latter, the attractive forces resume the ascendency, and arrange the particles in symmetrical forms. Mere approximation of the particles, however, is not alone sufficient for crystallisation. A hot saturated saline solution, when screened from all agitation, will contract by cooling into a volume much smaller than what it occupies in the solid state, without crystallising. Hence the molecules must not only be brought within a certain limit of each other, for their concreting into crystals; but they must also change the direction of their poles, from the fluid collocation to their position in the solid state.

This reversion of the poles may be effected, 1st, By contact of any part of the fluid with a point of a solid, of similar composition, previously formed. 2d, Vibratory motions communicated, either from the atmosphere or any other moving body, by deranging, however slightly, the fluid polar direction, will instantly determine the solid polar arrangement, when the balance had been rendered nearly even by previous removal of the interstitial fluid. On this principle we explain the regular figures which particles of dust or iron assume, when they are placed on a vibrating plane, in the neighbourhood of electrised or magnetised bodies. 3d, Negative or resinous voltaic electricity instantly determines the crystalline arrangement, while positive voltaic electricity counteracts it. Light also favours crystallisation, as is exemplified with camphor dissolved in spirits, which crystallises in bright and redissolves in gloomy weather.

It might be imagined, that the same body would always concrete in the same, or at least in a similar crystalline form. This position is true, in general, for the salts crystallised in the laboratory; and on this uniformity of figure, one of the principal criteria between different salts depends. But even these forms are liable to many modifications, from causes apparently slight; and in nature we find frequently the same chemical substance crystallised in forms apparently very dissimilar. Thus, carbonate of lime assumes the form of a rhomboid, of a regular hexaëdral prism, of a solid terminated by 12 scalene angles, or of a dodecahedron with pentagonal faces, &c. Bisulphuret of iron or martial pyrites produces sometimes cubes and sometimes regular octohedrons, at one time dodecahedrons with pentagonal faces, at another icosahedrons with triangular faces, &c.

While one and the same substance lends itself to so many transformations, we meet with very different substances, which present absolutely the same form. Thus fluate of lime, muriate of soda, sulphuret of iron, sulphuret of lead, &c. crystallise in cubes, under certain circumstances; and in other cases, the same minerals, as well as sulphate of alumina and the diamond, assume the form of a regular octohedron.

Romé de l'Isle first referred the study of crystallisation to principles conformable to observation. He arranged together, as far as possible, crystals of the same nature. Among the different forms relative to each species, he chose one as the most proper, from its simplicity, to be regarded as the primitive form; and by supposing it truncated in different ways, he deduced the other forms from it, and determined a gradation, a series of transitions between this same form and that of polyhedrons, which seem to be still further removed from it. To the descriptions and figures which he gave of the chrystalline forms, he added the results of the mechanical measurement of their principal angles, and showed that these angles were constant in each variety.

The illustrious Bergmann, by endeavouring to penetrate to the mechanism of the structure of crystals, considered the different forms relative to one and the same substance as produced by a superposition of planes, sometimes constant and sometimes variable, and decreasing around one and the same primitive form. He applied this primary idea to a small number of crystalline forms, and verified it with respect to a variety of calcareous spar by fractures, which enabled him to ascertain the position of the nucleus, or of the primitive form, and the successive order of the laminæ covering this nucleus. Bergmann, however, stopped here, and did not trouble himself either with determining the laws of structure, or applying calculation to it. It was a simple sketch of the most prominent point of view in mineralogy, but in which we see the hand of the same master who so successfully filled up the outlines of chemistry.

In the researches which Haüy undertook, about the same period, on the structure of crystals, he proposed combining the form and dimensions of integrant molecules with simple and regular laws of arrangement, and submitting these laws to calculation. This work produced a mathematical theory, which he reduced to analytical formulæ, representing every possible case, and the application of which to known forms leads to valuations of angles, constantly agreeing with observation."—*Ure's Chem. Dict.*

2. An eruption over the body of white transparent pustules.

CTE'DONES. (From κτηδων, a rake.) The fibres are so called from their pectinated course.

CTEIS. Κτεις. A comb or rake. *Ctenes*, in the plural number, implies those teeth which are called incisores, from their likeness to a rake.

CUBE ORE. Hexaëdral olivenite. *Wurfelerz* of Werner. A mineral arseniate of iron, of a pistachio-green colour.

CUBE SPAR. See *Anhydrite.*

CUBEB. See *Piper cubeba.*

CUBE'BA. (From *cubabah*, Arab.) See *Piper cubeba.*

CUBITÆUS EXTERNUS. An extensor muscle of the fingers. See *Extensor digitorum communis.*

CUBITÆUS INTERNUS. A flexor muscle of the fingers. See *Flexor sublimis*, and *profundus.*

CUBITAL. (*Cubitalis;* from *cubitus*, the fore-arm.) Belonging to the fore-arm.

CUBITAL ARTERY. *Arteria cubitalis; Arteria ulnaris.* A branch of the brachial that proceeds in the fore-arm, and gives off the recurrent and inter-osseals, and forms the palmary arch, from which arise branches going to the fingers, called digitals.

CUBITAL NERVE. *Nervus cubitalis; Nervus ulnaris.* It arises from the brachial plexus, and proceeds along the ulna.

CUBITALIS MUSCULUS. An extensor muscle of the fingers. See *Extensor.*

CU'BITUS. (From *cubo*, to lie down; because the ancients used to lie down on that part at their meals.) 1. The fore-arm, or that part between the elbow and wrist.

2. The larger bone of the fore-arm is called *os cubiti.* See *Ulna.*

CUBOI'DES OS. (From κυβος, a cube or die, and ειδος, likeness.) A tarsal bone of the foot, so called from its resemblance.

CUCKOW FLOWER. See *Cardamine.*

CUCU'BALUS. The name of an herb mentioned by Pliny. The name of a genus or family of plants in the Linnæan system. Class, *Decandria;* Order, *Trigynia.*

CUCUBALUS BACCIFERUS. The systematic name of the berry-bearing chick-weed, which is sometimes used as an emollient poultice.

CUCUBALUS BEHEN. The systematic name of the *Behen officinarum*, or spatling poppy, formerly used as a cordial and alexipharmic.

CUCULLA'RIS. (From *cucullus*, a hood: so named, because it is shaped like a hood.) See *Trapezius.*

CUCULLATUS. Hooded. Applied to a leaf when the edges meet in the lower part, and expand in the upper, forming a sheath or hood, of which the genus *Sarcacenia* are an example; to the nectary of the aconite tribe, &c.

CUCU'LLUS. 1. A hood.

2. An odoriferous cap for the head.

CUCUMBER. See *Cucumis.*

Cucumber, bitter. See *Cucumis colocynthis.*

Cucumber, squirting. See *Momordica elaterium.*

Cucumber, wild. See *Momordica elaterium.*

CU'CUMIS. (*Cucumis, mis.* m.; also *cucumer, ris; quasi curvimeres*, from their curvature.) The cucumber. 1. The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Syngenesia.* The cucumber.

2. The pharmacopœial name of the garden cucumber. See *Cucumis sativus.*

Cucumis agristis. See *Momordica elaterium.*

Cucumis asininus. See *Momordica elaterium.*

Cucumis colocynthis. The systematic name for the officinal bitter apple. *Colocynhis; Alhandula* of the Arabians. *Coloquintida.* Bitter apple: Bitter gourd; Bitter cucumber. The fruit, which is the medicinal part of this plant, *Cucumis—foliis multifidis, pomis globosis glabris,* of Linnæus, is imported from Turkey. Its spongy membranous medulla or pith, is directed for use; it has a nauseous, acrid, and intensely bitter taste; and is a powerful irritating cathartic. In doses of ten or twelve grains, it operates with great vehemence, frequently producing violent gripes, bloody stools, and disordering the whole system. It is recommended in various complaints, as worms, mania, dropsy, epilepsy, &c.; but is seldom resorted to, except where other more mild remedies have been used without success, and then only in the form of the *extractum colocynthidis compositum,* and the *pilulæ ex colocynthide cum aloë* of the pharmacopœias.

Cucumis melo. The systematic name of the melon plant. *Melo.* Musk melon. This fruit, when ripe, has a delicious refrigerating taste, but must be eaten moderately, with pepper, or some aromatic, as all this class of fruits are obnoxious to the stomach, producing spasms and cholic. The seeds possess mucilaginous qualities.

Cucumis sativus. The systematic name of the cucumber plant. *Cucumis. Cucumis—foliorum angulis rectis; pomis oblongis scabris* of Linnæus. It is cooling and aperient, but very apt to disagree with bilious stomachs. It should always be eaten with pepper and oil. The seeds were formerly used medicinally.

Cucumis sylvestris. See *Momordica elaterium.*

Cu'cupha. A hood. An odoriferous cap for the head, composed of aromatic drugs.

CUCU'RBITA. (*A curvitate,* according to Scaliger, the first syllable being doubled; as in *Cacula, Populus,* &c.) 1. The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Syngenesia.* The pumpion.

2. The pharmacopœial name of the common gourd. See *Cucurbita pepo.*

3. A chemical distilling vessel, shaped like a gourd.

Cucurbita citrullus. The systematic name of the water-melon plant. *Citrullus; Angura; Jace brasilientibus; Tetranguria.* Sicilian citrul, or water-melon. The seeds of this plant, *Cucurbita—foliis multipartitis* of Linnæus, were formerly used medicinally, but now only to reproduce the plant. Water-melon is cooling and somewhat nutritious; but so soon begins to ferment, as to prove highly noxious to some stomachs, and bring on spasms, diarrhœas, cholera, colics, &c.

Cucurbita lagenaria. The systematic name of the bottle-gourd plant. See *Curbita pepo.*

Cucurbita pepo. The systematic name of the common pumpion or gourd. *Cucurbita.* The seeds of this plant, *Cucurbita—foliis lobatis pomis lævibus,* are used indifferently with those of the *Cucurbita lagenaria—foliis subangulatis, tomentosis, basi subtus biglandulosis; pomis lignosis.* They contain a large proportion of oil, which may be made into emulsions; but is superseded by that of sweet almonds.

Cucurbitaceæ. (From *cucurbita,* a gourd.) The name of an order of Linnæus's Fragments of a Natural Method consisting of plants which resemble the gourd.

CUCURBI'TINUS. A species of worm, so called from its resemblance to the seed of the gourd. See *Tænia.*

CUCURBI'TULA. (A diminutive of *cucurbita,* a gourd; so called from its shape.) A cupping-glass.

Cucurbitula cruenta. A cupping-glass, with scarification to procure blood.

Cucurbitula cum ferro. A cupping-glass, with scarification to draw out blood.

Cucurbitula sicca. A cupping-glass, without scarification.

CUE'MA. (From κυω, to carry in the womb.) The conception, or rather, as Hippocrates signifies by this word the complete rudiments of the fœtus.

Culbi'cio. A sort of stranguary, or rather heat of urine.

Culila'wan. See *Laurus culilawan.*

CULI'NARY. (*Culinarius,* from *culina,* a kitchen.) Any thing belonging to the kitchen, as salt, pot-herbs, &c.

CULLEN, William, was born at Lanark, Scotland, in 1712, of respectable, but not wealthy parents. After the usual school education, he was apprenticed to a surgeon and apothecary at Glasgow, and then made several voyages as surgeon to the West Indies. He afterwards settled in practice at Hamilton, and formed a connexion with the celebrated William Hunter; but their business being scanty, they agreed to pass a winter alternately at some university. Cullen went first to Edinburgh, and attended the classes so diligently, that he was soon after able to commence teacher. Hunter came the next winter to London, and engaged as assistant in the dissecting-room of Dr. William Douglas, who was so pleased with his assiduity and talent, as to offer him a share in his lectures: but though the partnership with Cullen was thus dissolved, they continued ever after a friendly correspondence. Cullen had the good fortune, while at Hamilton, to assist the Duke of Argyle in some chemical pursuits: and still more of being sent for to the Duke of Hamilton, in a sudden alarming illness, which he speedily relieved by his judicious treatment, and gained the entire approbation of Dr. Clarke, who afterwards arrived. About the same time he married the daughter of a neighbouring clergyman, who bore him several children. In 1746 he took the degree of doctor in medicine, and was appointed teacher of chemistry at Glasgow. His talents were peculiarly fitted for this office; his systematic genius, distinct enunciation, lively manner, and extensive knowledge of the subject, rendered his lectures highly interesting. In the mean time his reputation as a physician increased, so that he was consulted in most difficult cases. In 1751 he was chosen professor in medicine to the university; and five years after the chemical chair at Edinburgh was offered him, on the death of Dr. Plummer, which was too advantageous to be refused. He soon became equally popular there, and his class increased, so as to exceed that of any other professor, except the anatomical. This success was owing not only to his assiduity, and his being so well qualified for the office, but also in a great measure to the kindness which he showed to his pupils, and partly to the new Views on the Theory of Medicine, which he occasionally introduced into his lectures. He appears also about this time to have given Clinical Lectures at the Infirmary. On the death of Dr. Alston, Lecturer on the Materia Medica, he was appointed to succeed him: and six years afterwards, jointly with Dr. Gregory, to lecture on the Theory and Practice of Medicine, when he resigned the Chemical Chair to his pupil, Dr. Black. Dr. Gregory having died the following year, he continued the Medical Lectures alone, till within a few months of his death, which happened in February 1790, in his seventy-seventh year; and he is said, even at the last, to have shown no deficiency in his delivery, nor in his memory, being accustomed to lecture from short notes. His Lectures on the Materia Medica being surreptitiously printed, he obtained an injunction against their being issued, until he had corrected them, which was accomplished in 1772: but they were afterwards much improved, and appeared in 1789, in two quarto volumes. Fearing a similar fate to his Lectures on Medicine, he published an outline of them in 1784, in four volumes, octavo, entitled "First Lines of the Practice of Physic." He wrote also the "Institutions of Medicine," in one volume, octavo: and a "Letter to Lord Cathcart, on the Recovery of drowned Persons." But his most celebrated work is his "Synopsis Nosologiæ Methodicæ," successively improved in different editions; the fourth published in 1785, in two octavo volumes, contains the Systems of other Nosologists till that period, followed by his own, which certainly, as a practical arrangement of diseases, greatly surpasses them.

CULMUS. Culm. Straw. The stem of grasses, rushes, and plants nearly allied to them. It bears both leaves and flowers, and its nature is more easily understood than defined. Its varieties are,

1. *Culmus teres*, round; as in *Carex uliginosa.*
2. *C. tetragonus;* as in *Festuca ovina.*
3. *C. triangularis;* as in *Eriocaulon triangulare.*
4. *C. capillaris;* as in *Scirpus capillaris.*
5. *C. prostratus;* as in *Agrostis canina.*
6. *C. repens;* as in *Agrostis stolonifera.*
7. *C. nudus*, as in *Carex montana.*
8. *C. enodis*, without joints; as in *Juncus conglomeratus.*
9. *C. articulatus*, jointed; as in *Agrostis alba.*
10. *C. geniculatus*, bent like the knee; as in *Alopecurus geniculatus.*

It is also either solid or hollow, rough or smooth, sometimes hairy or downy, scarcely wooly.

CULMIFERÆ. Plants which have smooth soft stems.

CULPEPER, NICHOLAS, was the son of a clergyman, who put him apprentice to an apothecary; after serving his time, he settled in Spitalfields, London, about the year 1642. In the troubles prevailing at that period, he appears to have favoured the Puritans; but his decided warfare was with the College of Physicians, whom he accuses of keeping the people in ignorance, like the Popish clergy. He therefore published a translation of their Dispensary, with practical remarks; also a Herbal, pointing out, among other matters, under what planet the plants should be gathered: and a directory to midwives, showing the method of insuring a healthy progeny, &c. These works were for some time popular. He died in 1654.

CU'LTER. (From *colo*, to cultivate.)

1. A knife or shear.
2. The third lobe of the liver is so called from its supposed resemblance.

CU'LUS. (From *κουλος*.) The anus or fundament.

CU'MAMUS. See *Piper cubeba.*

CUMIN. See *Cuminum.*

CU'MINUM. (From *κυω*, to bring forth; because it was said to cure sterility.)

1. The name of a genus of plants in the Linnæan system. Class, *Heptandria;* Order, *Digynia.* The cumin plant.
2. The pharmacopœial name of the cumin plant. See *Cuminum cyminum.*

CUMINUM ÆTHIOPICUM. A name for the ammi verum. See *Sison ammi.*

CUMINUM CYMINUM. The systematic name of the cumin plant. *Cuminum; Fœniculum orientale.* A native of Egypt and Ethiopia, but cultivated in Sicily and Malta, from whence it is brought to us. The seeds of cumin, which are the only part of the plant in use, have a bitterish taste, accompanied with an aromatic flavour, but not agreeable. They are generally preferred to other seeds for external use in discussing indolent tumours, as the encysted scrophulous, &c. and give name both to a plaster and cataplasm in the pharmacopœias.

CUNEA'DIS SUTURA. The suture by which the os sphenoides is joined to the os frontis.

CUNEIFORMIS. (From *cuneus*, a wedge, and *forma*, likeness.) Cuneiform, wedge-like. Applied to bones, leaves, &c. which are broad and abrupt at the extremity. See *Sphenoid bone; Tarsus*, and *Carpus; Leaf; Petalum.*

CUNE'OLUS. (From *cuneo*, to wedge.) A crooked tent to put into a fistula.

Cup of the flower. See *Calyx.*

CUPEL. (*Kuppel*, a cup, German.) *Copella; Catellus cinereus; Cineritium; Patella docimastica; Testa probatrix, exploratrix*, or *docimastica.* A shallow earthen vessel like a cup, made of phosphate of lime, which suffers the baser metals to pass through it, when exposed to heat, and retains the pure metal. This process is termed cupellation.

CUPELLATION. *Cupellatio.* The purifying of perfect metals by means of an addition of lead, which, at a due heat, becomes vitrified and promotes the vitrification and calcination of such imperfect metals as may be in the mixture, so that these last are carried off in the fusible glass that is formed, and the perfect metals are left nearly pure. The name of this operation is taken from the vessels made use of, which are called cupels.

CU'PHOS. *Κουφος.* Light. When applied to aliments, it imports their being easily digested; when to distempers, that they are mild.

CUPRE'SSUS. (So called, *απο του κυειν παρισους τους ακρεμονας*, because it produces equal branches.) Cypress.

1. The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Monadelphia.* The cypress-tree.
2. The pharmacopœial name of the cypress tree. See *Cupressus sempervirens.*

CUPRESSUS SEMPERVIRENS. The systematic name of the cupressus of the shops. *Cupressus —foliis imbricatis squamis quadrangulis*, of Linnæus; called also *cyparissus.* Every part of the plant abounds with a bitter, aromatic, terebinthinate fluid; and is said to be a remedy against intermittents. Its wood is extremely durable, and constitutes the cases of Egyptian mummies.

CUPRI AMMONIATI LIQUOR. Solution of ammoniated copper. *Aqua cupri ammoniati* of Pharm. Lond. 1787, and formerly called *Aqua sapphirina.* Take of ammoniated copper, a drachm; distilled water, a pint. Dissolve the ammoniated copper in the water, and filter the solution through paper. This preparation is employed by surgeons for cleansing foul ulcers, and disposing them to heal.

CUPRI RUBIGO. Verdigris.

Cupri sulphas. *Vitriolum cupri; Vitriolum cœruleum; Vitriolum Romanum; Cuprum vitriolatum.* Sulphate of copper. It possesses acrid and styptic qualities; is esteemed as a tonic, emetic, adstringent, and escharotic, and is exhibited internally in the cure of dropsies, hæmorrhages, and as a speedy emetic. Externally, it is applied to stop hæmorrhages, to hæmorrhoids, leucorrhœa, phagedænic ulcers, proud flesh, and condylomata.

CU'PRUM. (*Quasi æs Cyprium*: so called from the island of Cyprus, whence it was formerly brought.) See *Copper.*

Cuprum ammoniacale. See *Cuprum ammoniatum.*

Cuprum ammoniatum. *Cuprum ammoniacale.* Ammoniated copper. Ammoniacal sulphate of copper. Take of sulphate of copper, half an ounce; subcarbonate of ammonia, six drachms; rub them together in a glass mortar; till the effervescence ceases; then dry the ammoniated copper, wrapped up in bibulous paper, by a gentle heat. In this process the carbonic acid is expelled from the ammonia, which forms a triple compound with the sulphuric acid and oxide of copper. This preparation is much milder than the sulphate of copper. It is found to produce tonic and astringent effects on the human body. Its principal internal use has been in epilepsy, and other obstinate spasmodic diseases, given in doses of half a grain, gradually increased to five grains or more, two or three times a day. For its external application, see *Cupri ammoniati liquor.*

Cuprum vitriolatum. See *Cupri Sulphas.*

CUPULA. An accidental part of a seed, being a rough calyculus, surrounding the lower part of a gland, as that of the oak, of which it is the cup.

Cura avanacea. A decoction of oats and succory roots, in which a little nitre and sugar were dissolved, was formerly used in fevers, and was thus named.

Cu'rcas. See *Jatropha curcas.*

Cu'rculio. (From *karkarah*, Hebrew.) The throat and the aspera arteria.

Cu'rcum. See *Cheledonium majus.*

CURCU'MA. (From the Arabic *curcum*, or *hercum.*) Turmeric. 1. The name of a genus of plants in the Linnæan system. Class, *Monandria*; Order, *Monogynia.*

2. The pharmacopœial name of the turmeric-tree. See *Curcuma longa.*

Curcuma longa. The systematic name of the turmeric plant. *Crocus Indicus; Terra marita; Cannacorus radice croceo; Curcuma rotunda; Mayella; Kua kaha* of the Indians. *Curcuma—foliis lanceolatis; nervis lateralibus numerossimis* of Linnæus. The Arabians call every root of a saffron colour by the name of *curcum.* The root of this plant is imported here in its dried state from the East Indies, in various forms. Externally it is of a pale yellow colour, wrinkled, solid, ponderous, and the inner substance of a deep saffron or gold colour: its odour is somewhat fragrant; to the taste it is bitterish, slightly acrid, exciting a moderate degree of warmth in the mouth, and on being chewed, it tinges the saliva yellow. It is an ingredient in the composition of *Curry powder*, is valuable as a dyeing drug, and furnishes a chemical test of the presence of uncombined alkalies. It is now very seldom used medicinally, but retains a place in our pharmacopœias.

Curcuma rotunda. See *Curcuma longa.*

CURD. The coagulum, which separates from milk, upon the addition of acid or other substances.

Curled leaf. See *Leaf.*

CU'RMI. (From κεραω, to mix.) Ale. A drink made of barley, according to Dioscorides.

CURRANT. See *Ribes.*

Cu'rsuma. *Curtuma.* The *Ranunculus ficaria* of Linnæus.

Cursu'ta. (Corrupted from *cassuta, kasuth*, Arabian.) The root of the *Gentiana purpurea* of Linnæus.

Curva'tor coccygis. A muscle bending the coccyx. See *Coccygeus.*

CURVATUS. (From *curvus*, a curve.) Curvate, bent. Applied to the form of a pepo or gourd seed-vessel; as in *Cucumi flexuosus.*

CUSCU'TA. (According to Linnæus a corruption from the Greek Κασυτας, or Καδυτας, which is from the Arabic *Chessuth*, or *Chasuth.*) Dodder. 1. The name of a genus of plants in the Linnæan system. Class, *Tetrandria*; Order, *Digynia.*

2. The pharmacopœial name of dodder of thyme. See *Cuscuta epithymum.*

Cuscuta epithymum. The systematic name of dodder of thyme. *Epithymum. Cuscuta—foliis sessilibus, quinquifidis, bracteis obvallatis.* A parasitical plant, possessing a strong disagreeable smell, and a pungent taste, very durable in the mouth. Recommended in melancholia, as cathartics.

Cuscuta europæa. The systematic name of a species of dodder of thyme. *Cuscuta—floribus sessilibus*, of Linnæus.

CUSPA'RIA. The name given by Messrs. Humboldt and Bonpland to a genus of plants in which is the tree we obtain the Angustura bark from.

Cusparia febrifuga. This is the tree said to yield the bark called Angustúra—*Cortex cuspariæ*, and imported from Angustura in South America. Its external appearances vary considerably. The best is not fibrous, but hard, compact, and of a yellowish-brown colour, and externally of a whitish hue. When reduced into powder, it resembles that of Indian rhubarb. It is very generally employed as a febrifuge tonic, and adstringent. While some deny its virtue in curing intermittents, by many it is preferred to the Peruvian bark; and it has been found useful in diarrhœa, dyspepsia, and scrofula. It was thought to be the bark of the *Brucea antidysenterica*, or *ferruginea.* Willdenow suspected it to be the *Magnalia plumieri*; but Humboldt and Bonpland, the celebrated travellers in South America, have ascertained it to belong to a tree not before known, and which they promise to describe by the name of *Cusparia febrifuga.*

CUSPIDA'TUS. (From *cuspis*, a point.) 1. Four of the teeth are called *cuspidati*, from their form. See *Teeth.*

2. Sharp-pointed. Applied to leaves which are tipped with a spine, as in thistles. See *Leaf.*

CU'SPIS. (From *cuspa*, Chaldean, a shell, or bone, with which spears were formerly pointed.) 1. The glans penis was so called, from its likeness to the point of a spear.

2. The name of a bandage.

Cu'stos oculi. An instrument to fix the eye during an operation.

Cuta'mbulus. (From *cutis*, the skin, and *ambulo*, to walk.) 1. A cutaneous worm.

2. Scorbutic itching.

CUTANEOUS. (*Cutaneus*; from *cutis*, the skin.) Belonging to the skin.

Cuta'neus musculus. See *Platysma myoides.*

CUTICLE. *Cuticula.* (A diminutive of *cutis*, the skin.) *Epidermis.* Scarf-skin. A thin, pellucid, insensible membrane, of a white colour, that covers and defends the true skin, with which it is connected by the hairs, exhaling and inhaling vessels, and the rete mucosum.

CUTICULA. See *Cuticle.*

CU′TIS. (*Cutis, tis.* fœm.) See *Skin.*

Cutis anserina. The rough state the skin is sometimes thrown into from the action of cold, or other cause, in which it looks like the skin of the goose.

Cutis vera. The true skin under the cuticle.

CYANIA. The trivial name in Good's arrangement of diseases of a species called *Exangia cyania*, or blue skin. Class, *Hæmatica;* Order, *Struma.*

CYANIC ACID. *Acidum cyanicum.* See *Prussic acid.*

CYANITE. Kyanite. Disthene of Haüy. A mineral of a Berlin blue colour, found in India and Europe.

CYANOGEN. (From κυανος, blue, and γινομαι, to form.) Production of blue. See *Prussine.*

CY′ANUS. (Κυανος, cærulean, or sky-blue; so called from its colour.) Blue-bottle. See *Centauria cyanus.*

CY′AR. (From κεω, to pour out.) 1. The lip of a vessel.

2. The eye of a needle.

3. The orifice of the internal ear, from its likeness to the eye of a needle.

Cya′sma. Spots on the skin of pregnant women.

Cyathi′scus. (From κυαθος, a cup.) The hollow part of a probe, formed in the shape of a small spoon, as an ear-picker.

Cy′bitos. See *Cubitus.*

Cy′bitum. See *Cubitus.*

Cy′bitus. See *Cubitus.*

Cyboi′des. See *Cuboides.*

CYCAS. (Κυκας, of Theophrastus. The name of a palm, said to grow in Ethiopia.) The name of a genus of plants, one of the *Palmæ pinnatifoliæ*, of Linnæus; but afterwards removed by him to the *felices.*

Cycas circinalis. The systematic name of a palm-tree which affords a sago, called also *Sagus; Sagu:*—a dry fecula, obtained from the pith of this palm, in the islands of Java, Molucca, and the Philippines. The same substance is also brought from the West Indies, but it is inferior to that brought from the East. Sago becomes soft and transparent by boiling in water, and forms a light and agreeable liquid, much recommended in febrile, phthisical and calculous disorders, &c. To make it palatable, it is customary to add to it, when boiled or softened with water, some lemon juice, sugar and wine.

Cy′ceum. (From κυκαω, to mix.) *Cyceon.* A mixture of the consistence of pap.

Cy′cima. (From κυκάω, to mix.) So called from the mixture of the ore with lead, by which litharge is made.

CY′CLAMEN. (From κυκλος, circular; either on account of the round form of the leaves, or of the roots.) Cyclamen.

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia.*

2. The pharmacopœial name of the sow-bread. See *Cyclamen Europæum.*

Cyclamen europæum. The systematic name of the sow-bread. *Arthanita* of the pharmacopœias. The root is a drastic purge and errhine; and by the common people it has been used to procure abortion.

Cycli′scus. (From κυκλος, a circle.) An instrument in the form of a half-moon, formerly used for scraping rotten bones.

Cycli′smus. (From κυκλος, a circle.) A lozenge.

Cyclopho′ria. (From κυκλος, a circle, and φερω, to bear.) The circulation of the blood, or other fluids.

Cyclo′pion. (From κυκλοω, to surround, and ωψ, the eye.) The white of the eye.

CY′CLOS. *Cyclus.* A circle. Hippocrates uses this word to signify the cheeks, and the orbits of the eyes.

Cyclus metasyncriticus. A long protracted course of remedies, persisted in with a view of restoring the particles of the body to such a state as is necessary to health.

CYDO′NIA. (From *Cydon*, a town in Crete, where the tree grows wild.) The quince-tree. See *Pyrus cydonia.*

Cydonium malum. The quince. See *Pyrus cydonia.*

CYE′MA. (From κυω, to bring forth.) Parturition.

Cyli′chnis. (From κυλιξ, a cup.) A gallipot or vessel to hold medicines.

Cylindrical Leaf. See *Leaf.*

CYLI′NDRUS. (From κυλιω, to roll round.) A cylinder. A tent for a wound, equal at the top and bottom.

Cyllo′sis. (From κυλλοω, to make lame.) A tibia or leg bending outwards.

Cy′lus. (From κυλλοω, to make lame.) In Hippocrates, it is one affected with a kind of luxation, which bends outwards, and is hollowed inward. Such a defect in the tibia is called *Cyllosis*, and the person to whom it belongs, is called by the Latins *Varus*, which term is opposed to *Valgus.*

CYMA. A cyme. A species of inflorescence of plants, consisting of several flower-stalks, all springing from one centre or point, but each stalk is variously subdivided; and in this last respect, a cyme differs essentially from an umbel, the subdivisions of the latter being formed like its primary divisions, of several stalks springing from one point. This difference is of great importance in nature. The mode of inflorescence agrees also with a corymbus in general aspect; but in the latter the primary stalks have no common centre, though the partial ones may sometimes be umbellate, which last case is precisely the reverse of a cyme.

From its division into primary stalks or branches, it is distinguished into,

1. *Trifid;* as in *Sedum acre.*
2. *Quadrifid;* as in *Crassula rubens.*
3. *Tripartite*, having three lesser cymes; as in *Sambucus ebulus.*
4. *Quinquipartite;* as in *Sambucus nigra.*
5. *Sessile*, or without stalk; as in *Gnaphalium frutescens.*

Comus sanguinea and *sericea* afford examples of the *Cyma nuda.*

Cymato′des. Is applied by Galen and others to an unequal fluctuating pulse.

Cy′mba. (From κυμβος, hollow.) A boat, pinnace, or skiff. A bone of the wrist is so called, from its supposed likeness to a skiff. See *Naviculare os.*

CYMBIFORMIS. (From *cymba*, a boat or skiff, and *forma*, likeness.) Skiff or boat-like. Applied to the seeds of the *Calendula officinalis.*

CY′MINUM. See *Cuminum.*

CYMOPHANE. See *Chrysoberyl.*

Cymosus. Having the character of a cyme. Applied to aggregate flowers.

CYNA'NCHE. (From κυων, a dog, and αγχω, to suffocate, or strangle; so called from dogs being said to be subject to it.) Sore throat. A genus of disease in the class *Pyrexiæ*, and order *Phlegmasiæ* of Cullen. It is known by pain and redness of the throat, attended with a difficulty of swallowing and breathing.

The species of this disease are :—

1. *Cynanche trachealis; Cynanche laryngea; Suffocatio stridula; Angina perniciosa; Asthma infantum; Cynanche stridula; Morbus strangulatorius; Catarrhus suffocatius; Barbadensis; Angina polyposa sive membranacea.* The croup. A disease that mostly attacks infants, who are suddenly seized with a difficulty of breathing and a crouping noise: it is an inflammation of the mucous membrane of the trachea that induces the secretion of a very tenacious coagulable lymph, which lines the trachea and bronchia, and impedes respiration. The croup does not appear to be contagious, whatever some physicians may think to the contrary; but it sometimes prevails epidemically. It seems, however, peculiar to some families; and a child having once been attacked, is very liable to its returns. It is likewise peculiar to young children, and has never been known to attack a person arrived at the age of puberty.

The application of cold seems to be the general cause which produces this disorder, and therefore it occurs more frequently in the winter and spring, than in the other seasons. It has been said, that it is most prevalent near the sea-coast; but it is frequently met with in inland situations, and particularly those which are marshy.

Some days previous to an attack of the disease, the child appears drowsy, inactive, and fretful; the eyes are somewhat suffused and heavy; and there is a cough, which, from the first, has a peculiar shrill sound; this, in the course of two days, becomes more violent and troublesome, and likewise more shrill. Every fit of coughing agitates the patient very much; the face is flushed and swelled, the eyes are protuberant, a general tremor takes place, and there is a kind of convulsive endeavour to renew respiration at the close of each fit. As the disease advances, a constant difficulty of breathing prevails, accompanied sometimes with a swelling and inflammation in the tonsils, uvula, and velum pendulum palati; and the head is thrown back, in the agony of attempting to escape suffocation. There is not only an unusual sound produced by the cough, (something between the yelping and barking of a dog,) but respiration is performed with a hissing noise, as if the trachea was closed up by some slight spongy substance. The cough is generally dry; but if any thing is spit up, it has either a purulent appearance, or seems to consist of films resembling portions of a membrane. Where great nausea and frequent retchings prevail, coagulated matter of the same nature is brought up. With these symptoms, there is much thirst, and uneasy sense of heat over the whole body, a continual inclination to change from place to place, great restlessness, and frequency of the pulse.

In an advanced stage of the disease, respiration becomes more stridulous, and is performed with still greater difficulty, being repeated at longer periods, and with greater exertions, until at last it ceases entirely.

The croup generally proves fatal by suffocation, induced either by spasm affecting the glottis, or by a quantity of matter blocking up by the trachea or bronchia; but when it terminates in health, it is by a resolution of the inflammation, by a ceasing of the spasms, and by a free expectoration of the matter exuding from the trachea, or of the crusts formed there.

The disease has, in a few instances, terminated fatally within twenty-four hours after its attack; but it more usually happens, that where it proves fatal, it runs on to the fourth or fifth day. Where considerable portions of the membranous films, formed on the surface of the trachea, are thrown up, life is sometimes protracted for a day or two longer than would otherwise have happened.

Dissections of children who have died of the croup, have mostly shown a preternatural membrane, lining the whole internal surface of the upper part of the trachea, which may always be easily separated from the proper membrane. There is likewise usually found a good deal of mucus, with a mixture of pus, in the trachea and its ramifications.

The treatment of this disease must be conducted on the strictly antiphlogistic plan. It will commonly be proper, where the patient is not very young, to begin by taking blood from the arm, or the jugular vein; several leeches should be applied along the fore part of the neck. It will then be right to give a nauseating emetic, ipecacuanha with tartarized antimony, or with squill in divided doses; this may be followed up by cathartics, diaphoretics, digitalis, &c. Large blisters ought to be applied near the affected part, and a discharge kept up by savine cerate, or other stimulant dressing. Mercury, carried speedily to salivation, has in several instances arrested the progress of the disease, when it appeared proceeding to a fatal termination. As the inflammation is declining, it is very important that free expectoration should take place; this may be promoted by nauseating medicines, by inhaling steam, and by stimulating gargles; for which the decoction of seneka is particularly recommended. Where there is much wheezing, an occasional emetic may relieve the patient considerably, and under symptoms of threatening suffocation, the operation of bronchotomy has sometimes saved life. Should fits of spasmodic difficulty of breathing occur in the latter periods of the disease, opium joined with diaphoretics would be most likely to do good.

2. *Cynanche tonsillaris.* The inflammatory quincy, called also *angina inflammatoria.* In this complaint, the inflammation principally occupies the tonsils; but often extends through the whole mucous membrane of the fauces, so as essentially to interrupt the speech, respiration, and deglutition of the patient.

The causes which usually give rise to it are, exposure to cold, either from sudden vicissitudes of weather, from being placed in a partial current of air, wearing damp linen, sitting in wet rooms, or getting wet in the feet; all of which may give a sudden check to perspiration. It principally attacks those of a full and plethoric habit, and is chiefly confined to cold climates, occurring usually in the spring and autumn; whereas the ulcerated sore throat chiefly attacks those of a weak irritable habit, and is most prevalent in warm climates. The former differs from the latter likewise in not being contagious. In many people there seems to be a particular tendency to this disease; as from every considerable application of cold it is readily induced.

An inflammatory sore throat discovers itself by a difficulty of swallowing and breathing, accompanied by a redness and tumour in one or both tonsils, dryness of the throat, foulness of the tongue, lancinating pains in the parts affected, a frequent but difficult excretion of mucus, and some small degree of fever. As the disease advances, the difficulty of swallowing and breathing becomes greater, the speech is very indistinct, the dryness of the throat and thirst increases, the tongue swells and is incrusted with a dark fur, and the pulse is full and frequent. In some cases, a few white, sloughy spots are to be observed on the tonsils. If the inflammation proceeds to such a height as to put a total stop to respiration, the face will become livid, the pulse will sink, and the patient will quickly be destroyed.

The chief danger arising from this species of quincy is, the inflammation occupying both tonsils, and proceeding to such a degree as to prevent a sufficient quantity of nourishment for the support of nature from being taken, or to occasion suffocation; but this seldom happens, and its usual termination is either in resolution or suppuration. When proper steps are adopted, it will in general readily go off by the former.

Where the disease has proved fatal by suffocation, little more than a highly inflamed state of the parts affected, with some morbid phenomena in the head, have been observed on dissection.

This is usually a complaint not requiring very active treatment. If, however, the inflammation run high, in a tolerably strong and plethoric adult, a moderate quantity of blood should be drawn from the arm, or the jugular vein: but still more frequently leeches will be required; or scarifying the tonsils may afford more effectual relief. An emetic will often be very beneficial, sometimes apparently check the progress of the complaint: likewise cathartics must be employed, diaphoretics, and the general antiphlogistic regimen. A blister to the throat, or behind the neck, sometimes has a very excellent effect: but in milder cases, the linimentum ammoniæ, or other rubefacient application, applied every six or eight hours, and wearing flannel round the throat, may produce a sufficient determination from the part affected. The use of proper gargles generally contributes materially to the cure. If there be much tension and pain in the fauces, a solution of nitrate of potassa will be best; otherwise dilute acids, a weak solution of alum, &c. Should the disease proceed to suppuration, warm emollient gargles ought to be employed, and perhaps similar external applications may be of some service: but it is particularly important to make an early opening into the abscess for the discharge of the pus. When deglutition is prevented by the tumefaction of the tonsils, it is recommended to exhibit nutritious clysters; and when suffocation is threatened, an emetic, or inhaling æther, may cause a rupture of the abscess, or this may be opened; but if relief be not thereby obtained, bronchotomy will become necessary.

3. *Cynanche pharyngea.* This species is so called when the pharynx is chiefly affected. Dr. Wilson, in his treatise on Febrile Diseases, includes in his definition of cynanche tonsillaris, that of cynanche pharyngea. These varieties of cynanche differ considerably when they are exquisitely formed. But the one is seldom present in any considerable degree, without being attended with more or less of the other. Dr. Cullen declares, indeed, that he never saw a case of true cynanche pharyngea; that is, a case in which the inflammation was confined to the pharynx; it constantly spread in a greater or less degree to the tonsils and neighbouring parts. Besides, the mode of treatment is, in almost every instance, the same in both cases. And if we admit the cynanche pharyngea to be a distinct variety, we must admit another, the cynanche œsophagea; for inflammation frequently attacks the œsophagus, and is sometimes even confined to it.

4. *Cynanche parotidea.* The mumps. A swelling on the cheek and under the jaw, extending over the neck, from inflammation of the parotid and other salivary glands, rendering deglutition, or even respiration, sometimes difficult, declining the fourth day. Epidemic and contagious.

The disease is subject to a metastasis occasionally, in females, to the mammæ, in males to the testes; and in a few instances, repelled from these parts, it has affected the brain, and even proved fatal. In general, however, the disease is without danger, and scarcely calls for medical aid. Keeping a flannel over the part, and the antiphlogistic regimen, with mild laxatives, will be sufficient. Should the mammæ, or the testes, be affected, more active evacuations may be necessary to prevent the destruction of those organs, bleeding general and topical, &c. but avoiding cold applications, lest it should be driven to the brain. And where this part is unfortunately attacked, besides the means explained under *Phrenitis*, it may be useful to endeavour to recall the inflammation to its former seat by warm fomentations, stimulant liniments, &c.

5. *Cynanche maligna.* The malignant, putrid, or ulcerous sore throat. Called also *Cynanche gangrænosa; Angina ulcerosa; Febris epidemica cum angina ulcusculosa; Angina epidemica; Angina gangrænosa; Angina suffocativa; Angina maligna.* This disease is readily to be distinguished from the inflammatory quincy, by the soreness and specks which appear in the fauces, together with the great debility of the system, and small fluttering pulse, which are not to be observed in the former. In the inflammatory sore throat there is always great difficulty of swallowing, a considerable degree of tumour, with a tendency in the parts affected to suppurate, and a hard, full pulse. Moreover in the former affection the disease is seated principally in the mucous membrane of the mouth and throat; whereas in the latter the inflammation chiefly occupies the glandular parts.

The putrid sore throat often arises from a peculiar state of the atmosphere, and so becomes epidemical; making its attacks chiefly on children, and those of a weak relaxed habit. It is produced likewise by contagion, as it is found to run through a whole family, when it has once seized any person in it; and it proves often fatal, particularly to those in an infantile state.

It appears, however, that under this head two different complaints have been included; the one, especially fatal to children, is an aggravated form of scarlatina; the other, a combination of inflammation of the fauces with typhus fever; the former is perhaps always, the latter certainly often, contagious. See *Scarlatina* and *Typhus.*

CYNA'NCHICA. (*Cinanchicus;* from κυναγχη, the quincy.) Medicines which relieve a quincy.

CYNANTHRO'PIA. (From κυων, a dog, and ανθρωπος, a man.) It is used by Bellini, De Morbis Capitis, to express a particular kind of melancholy, when men fancy themselves changed into dogs, and imitate their actions.

CY'NARA. See *Cinara.*

CYNAROCEPHALUS. (From κιναρα, the artichoke, and κεφαλη, a head.) Having a head like the *Cinara*, or artichoke; as the thistle, globe thistle, burdock, blue bottle.

CY'NCHNIS. Κυγχνις. A vessel of any kind to hold medicines in.

CYNOCRA'MBE. (From κυων, a dog, and

κραμβη, cabbage; an herb of the cabbage tribe, with which dogs are said to physic themselves.) See *Mercurialis perennis.*

CYNO'CTANUM. (From κυων, a dog, and κτεινω, to kill.) A species of aconitum, said to destroy dogs. See *Aconitum napellus.*

CYNOCY'TISIS. (From κυων, a dog, and κυτισος, the cytisus: so named because it was said to cure the distemper of dogs.) The dog-rose. See *Rosa canina.*

CYNODE'CTOS. (From κυων, a dog, and δακνω, to bite.) So Dioscorides calls a person bit by a mad dog.

CYNODE'SMION. (From κυων, a dog, and δεω, to bind; so named because in dogs it is very discernible and strong.) A ligature by which the prepuce is bound to the glands. See *Frænum.*

CYNODO'NTES. (Κυνοδοντες: from κυων, a dog, and οδους, a tooth.) The canine teeth. See *Teeth.*

CYNOGLO'SSUM. (From κυων, a dog, and γλωσσα, a tongue; so named from its supposed resemblance.) Hound's tongue.

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia.*

2. The pharmacopœial name of the hound's tongue. See *Cynoglossum officinale.*

CYNOGLOSSUM OFFICINALE. The systematic name for hound's tongue. *Cynoglossum; Lingua canina; Cynoglossum—staminibus corollâ brevioribus; foliis lato lanceolatis, tomentosis, sessilibus,* of Linnæus. It possesses narcotic powers, but is seldom employed medicinally. Acids are said to counteract the ill effects from an over-dose more speedily than any thing else, after clearing the stomach.

CYNO'LOPHUS. (From κυων, a dog, and λοφος, a protuberance: so called because in dogs they are peculiarly eminent.) The asperities and prominences of the vertebræ.

CYNOLY'SSA. (From κυων, a dog, and λυσση, madness.) Canine madness.

CYNOMO'RIUM. The name of a genus of plants in the Linnæan system. Class, *Monœcia*; Order, *Monandria.*

CYNOMORIUM COCCINEUM. The systematic name of the *Fungus melitensis*; improperly called a fungus. It is a small plant which grows only on a little rock adjoining Malta. A drachm of the powder is given for a dose in dysenteries and hæmorrhages, and with remarkable success.

CYNORE'XIA. (From κυων, a dog, and ορεξις, appetite.) A voracious or canine appetite. See *Bulimia.*

CYNO'SBATOS. See *Cynosbatus.*

CYNO'SBATUS. (From κυων, a dog, and βατος, a thorn: so called because dogs are said to be attracted by its smell.) The dog-rose. See *Rosa canina.*

CYNOSPA'STUM. (From κυων, a dog, and σπαω, to attract.) See *Rosa canina.*

CYOPHO'RIA. (From κυος, a fœtus, and φερω, to bear.) Pregnancy.

CYPARI'SSUS. See *Cupressus.*

CY'PERUS. (From κυπαρος, a little round vessel, which its roots are said to resemble.) Cyperus. The name of a genus of plants in the Linnæan system. Class, *Triandria*; Order, *Monogynia.*

CYPERUS ESCULENTUS. The rush-nut. This plant is a native of Italy where the fruit is collected and eaten, and said to be a greater delicacy than the chesnut.

CYPERUS LONGUS. The systematic and pharmacopœial name of the English galangale. *Cyperus—culmo triquetro folioso, umbella foliosa supra-decomposita; pedunculis nudis, spicis alternis,* of Linnæus. The smell of the root of this plant is aromatic, and its taste warm, and sometimes bitter. It is now totally fallen into disuse.

CYPERUS ROTUNDUS. This species, the round cyperus, *Cyperus—culmo triquetro subnudo, umbella decomposita; spicis alternis linearibus,* of Linnæus, is generally preferred to the former, being a more gratefully aromatic bitter. It is chiefly used as a stomachic.

CYPHELLA. A peculiar sort of pit or pore on the under side of the frond, in that section of lichens called *stricta.*

CYPHO'MA. (From κυπτω, to bend.) A gibbosity, or curvature of the spine.

CYPHO'SIS. An incurvation of the spine.

CYPRESS. See *Cyprus.*

Cypress spurge. See *Esula minor.*

CYPRINUM OLEUM. Flowers of cypress, calamus, cardamoms, &c. boiled in olive oil, now fallen into disuse.

CY'PRIUM. (From Κυπρος, Cyprus, an island where it is said formerly to have abounded.) Copper.

CY'PRUS. So called from the island of Cyprus, where it grew abundantly.) The cypress-tree, or Eastern privet.

CY'PSELIS. (From κυψελη, a bee hive.) The aperture of the ear, also the wax of the ear.

CYRCNE'SIS. (From κυρκναω, to mix.) A mixture, or composition.

CYRTO'MA. (From κυρτος, curved.) 1. An unnatural convex tumour.

2. Tympanites.

CYRTONO'SUS. (From κυρτος, curved, and νοσος, a disease.) 1. The rickets.

2. Curved spine.

CYRTOSIS. (*Cyrtosis, is.* f.; from κυρτος, *curvus, incurvus, gibbosus,* and among the ancients particularly imputed recurvation of the spine, or posterior crookedness, as λορδασις, imputed procurvation of the head and shoulders, or anterior crookedness.) The name of a genus of diseases in Good's Nosology. Class, *Eccritica*; Order, *Mesotica.* Contortion of the bones; defined, head bulky, especially anteriorly; stature short and incurvated; flesh flabby, pale, and wrinkled. It has two species, *Cyrtosis rhachia,* the rickets, and *C. cretenismus,* cretenism.

CY'SSARUS. (From κυσος, the anus.) The intestinum rectum is so called, because it reaches to the anus.

CYSSO'TIS. (From κυσος, the anus.) An inflammation of the anus.

CYSTEOLI'THUS. (From κυστις, the bladder, and λιθος, a stone.) A stone in the bladder, either urinary or gall-bladder.

CY'STHUS. Κυσθος. The anus.

CYSTIC. (*Cysticus*; from κυστις, a bag.) Belonging to the urinary or gall bladder.

CYSTIC DUCT. See *Ductus cysticus.*

CYSTIC OXIDE. A peculiar animal product discovered by Dr. Wollaston. See *Calculus urinary.*

CY'STICA. (*Cysticus*; from κυστις, the bladder.) Remedies for diseases of the bladder.

CY'STIDES. (*Cystis, idis.* f.; from κυστις, a bag.) Encysted tumours.

CYSTIPHLO'GIA. (From κυστις, the bladder, and φλεγω, to burn.) An inflammation in the bladder. See *Cystitis.*

CYSTIRRHA'GIA. (From κυστις, the bladder, and ῥηγνυμι, to burst forth.) A discharge from the bladder.

CY'STIS. (Κυστις, a bag.) 1. Cyst or bladder.

2. The urinary bladder.

3. The membranous or cyst surrounding or containing any morbid substance.

Cystis choledocha. See *Gall-bladder.*

Cystis fellea. See *Gall-bladder.*

Cystis urinaria. See *Urinary bladder.*

CYSTI′TIS. (From κυϛις, the bladder.) Inflammation of the bladder. A genus of disease arranged by Cullen in the class *Pyrexiæ*, and order *Phlegmasiæ.* It is known by great pain in the region of the bladder, attended with fever and hard pulse, a frequent and painful discharge of urine, or a suppression, and generally tenesmus. This is rarely a primary disease, and when it occurs, the above character of it will readily point it out. There also is frequently nausea and vomiting, and, in some cases, delirium. It most generally arises in consequence of inflammation of the adjacent parts, or from calculi in the bladder. The treatment is very similar to that of *Nephritis;* which see. When suppression of urine attends, the catheter must be occasionally introduced.

CYSTOCE′LE. (From κυϛις, the bladder, and κηλη, a tumour.) An hernia formed by the protusion of the urinary bladder.

CYSTOLI′THICUS. (From κυϛις, the bladder, and λιθος, a stone.) Having a stone in the bladder.

CYSTOPHLE′GICUS. (From κυϛις, the bladder, and φλεγω, to burn.) An inflammation of the bladder.

CYSTOPHLEGMA′TICUS. (From κυϛις, the bladder, and φλεγμα, phlegm.) Having matter or mucus in the bladder.

CYSTOPRO′CTICUS. (From κυϛις, the bladder, and ϖρωκτος, the anus, or rectum.) A disease of the bladder and rectum.

CYSTOPTO′SIS. (From κυϛις, the bladder, and ϖιπτω, to fall.) A protrusion of the inner membrane of the bladder, through the urethra.

CYSTOSPA′STICUS. (From κυϛις, the bladder, and σπασμα, a spasm.) A spasm in the sphincter of the bladder.

CYSTOSPY′ICUS. (From κυϛις, the bladder, and ϖυον, pus.) Purulent matter in the bladder.

CYSTOTHROMBOI′DES. (From κυϛτς, the bladder, and θρομβος, a coagulation of blood.) A concretion of grumous blood in the bladder.

CYSTOTO′MIA. (From κυϛις, the bladder, and τεμνω, to cut.) The operation of cutting or piercing the bladder.

Cy′thion. An eye-wash.

CY′TINUS. (Perhaps, as Martyn suggests, from κυτινοι, a name given by Theophrastus to the blossoms of the pomegranate, the calyx of which the flower in question resembles in shape.) The name of a genus of plants. Class, *Gynandria;* Order, *Octandria* of Linnæus.

Cytinus hypocistis. Rape of Cystus. A fleshy pale-yellowish plant, parasitical on the roots of several species of cystus in the south of Europe, from which the *succus hypocistidis* is obtained.

Cytiso-genista. Common broom. See *Spartium scoparium.*

Cyzemer. A swelling of the wrists.

Cyzice′nus. A plaster for wounds of the nerves.

D

D. This letter signifies vitriol in the old chemical alphabet.

Dacne′rus. (From δακνω, to bite.) Biting. Pungent. An epithet for a sharp eye-wash, composed of burnt copper, pepper, cadmia, myrrh, and opium.

Dacry′dium. (From δακρυ, a tear.) The inspissated juice of scammony, in small drops, and therefore called a tear.

DACRYGELO′SIS. (From δακρυω, to weep, and γελαω, to laugh.) A species of insanity, in which the patient weeps and laughs at the same time.

Dacryo′des. (From δακρυω, to weep.) A sanious, or weeping ulcer.

DACRYO′MA. (From δακρυω, to weep.) A closing of one or more of the puncta lachrymalia, causing an effusion of tears.

Dactyle′thra. (From δακτυλος; a finger.) A species of bougies shaped like a finger, to excite vomiting.

Dactyle′tus. (From δακτυλος, the date.) The hermodactyl. See *Hermodactylus.*

Da′ctylius. (From δακτυλος, a finger.) A round pastil, troche, or lozenge, shaped like a finger.

DA′CTYLUS. (From δακτυλος, a finger; so called from the likeness of its fruit to a finger.) 1. A finger. See *Digitus.*

2. The date. See *Phœnix dactylifera.*

DÆ′DIUM. (From δαις, a torch.) A small torch or candle. A bougie.

DÆMONOMA′NIA. (From δαιμων, a dæmon, and μανια, madness.) That species of melancholy where the patient supposes himself to be possessed by devils.

DAISY. See *Bellis perennis.*

Daisy, ox-eye. See *Chrysanthemum leucanthemum.*

DALE, Samuel, was born in 1659. After practising as an apothecary, he became a licentiate of the college of physicians, and settled at Bocking, where he continued till his death in 1739. He was also chosen a fellow of the Royal Society. In 1693 he published his "Pharmacologia," an Introduction to the Materia Medica, which he afterwards much enlarged and improved: the work was well received, and passed through many editions. He also gave a good account of the natural productions about Harwich and Dover Court.

Damask rose. See *Rosa centifolia.*

Damna′tus. (From *damno*, to condemn.) The dry useless fæces, left in a vessel after the moisture has been distilled from it, is called terra damnata, or *caput mortuum.*

DAMSON. The fruit of a variety of the *Prunus domestica.*

DANDELION. See *Leontodon Taraxacum.*

DANDRIF. See *Pityriasis.*

DANEWORT. See *Sambucus Ebulus.*

DAOURITE. A variety of red schorl from Siberia.

DA′PHNE. (*Daphne*, δαφνη; from δαω, to burn, and φωνη, a noise: because of the noise it makes when burnt.) The name of a genus of plants in the Linnæan system. Class, *Octan-*

dria; Order, *Monogynia.* The laurel, or bay-tree.

Daphne alpina. *Chamælea; Chamelæa.* This species of dwarf olive-tree is said to be purgative in the dose of ʒjj, and is sometimes given by country people. The French chemists have lately examined it chemically. See *Daphnin.*

2. The mezereon is also so called, because it has leaves like the olive-tree. See *Daphne mezereum.*

Daphne, flax-leaved. See *Daphne gnidium.*

Daphne gnidium. The systematic name of the tree which affords the Garou bark. *Daphne:—panicula terminali foliis lineari-lanceolatis acuminatis* of Linnæus. *Thymelæa; Oneoron.* Spurge-flax; Flax-leaved Daphne. Garou bark, which very much resembles that of our mezereum, is to be immersed in vinegar for about an hour before it is wanted; a small piece, the size of a sixpence, thus steeped, is applied to the arm or any other part, and renewed once a day in winter and twice in summer. It produces a serous exudation from the skin without irritating or blistering. It is recommended, and is in frequent use in France and Russia, against some diseases of the eyes.

Daphne laureola. The systematic name of the spurge-laurel. *Laureola daphnoides.* The bark of this plant is recommended to excite a discharge from the skin, in the same way as that of the *Daphne gnidium.*

Daphne mezereum. The systematic name of the mezereon. Spurge-olive; Widow-wail. *Mezereum. Daphne—floribus sessilibus ternis caulinis, foliis lanceolatis deciduis,* of Linnæus. This plant is extremely acrid, especially when fresh, and, if retained in the mouth, excites great and long-continued heat and inflammation, particularly of the mouth and fauces; the berries, *grana cnidii* of old writers, also have the same effects, and, when swallowed, prove a powerful corrosive poison, not only to man, but to dogs, wolves, and foxes. The bark of the root is the part employed medicinally in the *decoctum sarsaparillæ compositum,* intended to assist mercury in resolving nodes and other obstinate symptoms of syphilis. The antisyphilitic virtues of mezereum, however, have been by many writers very justly doubted. "The result of my own experience (says Mr. Pearson, of the Lock Hospital) by no means accords with the representation given of this root by former writers. From all that I have been able to collect, in the course of many years' observation, I feel myself authorised to assert, unequivocally, that the mezereum has not the power of curing the venereal disease in any one stage, or under any one form. If a decoction of this root should ever reduce a venereal node, where no mercury has been previously given, yet the patient will by no means be exempted from the necessity of employing mercury for as long a space of time, and in as large a quantity, as if no mezereum had been taken. With respect to the power it is said to possess, of alleviating the pain, and diminishing the bulk of membranous nodes, nothing peculiar and appropriate can be ascribed to the mezereum on these accounts, since we obtain the same good effects from sarsaparilla, guaiacum, volatile alkali, blistering plaisters, &c. Nevertheless, venereal nodes, which have subsided under the use of any of these articles of the materia medica, will appear again, and often with additional symptoms, if a full and efficacious course of mercury be not submitted to. It has, indeed, been alleged, that mezereum always alleviates the pain occasioned by a venereal node, and generally reduces it, where the periosteum only is affected; and that it seldom fails of removing those enlargements of the periosteum which have not yielded during the administration of mercury.

That some instances of success, in cases like these, may have fallen to the share of those who made the assertion, it would not become me to deny; but I have met with few such agreeable evidences of the efficacy of this medicine. I have given the mezereum in the form of a simple decoction, and also as an ingredient in compound decoctions of the woods, in many cases, where no mercury had been previously employed, but never with advantage to a single patient. I have also tried it, in numerons instances, after the completion of a course of mercury; yet, with the exception of two cases, where the thickened state of the periosteum was removed during the exhibition of it, I never saw the least benefit derived from taking this medicine. In a few cases of anomalous pains, which I supposed were derived from irregularities during a mercurial course, the mezereum was of service, after I had tried the common decoction of the woods without success; but even in this description of cases, I have always found it a very uncertain remedy. I have made trial of this vegetable in a great number of scrofulous cases, where the membranes covering the bones were in a diseased state, and I am not sure that one single patient obtained any evident and material benefit from it.

The late Dr. Cullen, whose reports may justly claim attention from all medical men, when treating of the mezereum, in his Materia Medica, says, 'I have frequently employed it in several cutaneous affections, and sometimes with success.' It were to have been wished, that the professor of medicine had specified what those diseases of the skin were, in which the mezereum was sometimes employed with success; for, if I except an instance or two of lepra, in which the decoction of this plant conferred a temporary benefit, I have very seldom found it possessed of medicinal virtue, either in syphilis, or in the sequelæ of that disease, in scrofula or in cutaneous affections. Indeed the mezereum is of so acrimonious a nature, often producing heat and other disagreeable sensations in the fauces, and, on many occasions, disordering the primæ viæ, that I do not often subject my patients, to the certain inconveniences which are connected with the primary effects of this medicine, as they are rarely compensated by any other important and useful qualities."

DAPHNELÆ'ON. (From δαφνη, the laurel, and ελαιον, oil.) The oil of bay-berries.

DAPHNIN. The bitter principle of the *Daphne alpina,* discovered by Vauquelin. From the alkoholic infusion of this bark, the resin was separated by its concentration. On diluting the tincture with water, filtering and adding acetate of lead, a yellow *daphnate* of lead fell, from which sulphuretted hydrogen separated the lead, and left the daphnin in small transparent crystals. They are hard, of a greyish colour, a bitter taste when heated, evaporate in acrid acid vapours, sparingly soluble in cold, but moderately in boiling water. It is stated, that its solution is not precipitated by acetate of lead; yet acetate of lead is employed in the first process to throw it down.

Daphni'tis. (From δαφνη, the laurel.) A sort of cassia resembling the laurel.

DAPHNOI'DES. (From δαφνη, the laurel, and ειδος, a likeness.) The herb spurge laurel. See *Daphne laureola.*

Da'rsin. (From *darzin,* Arabian.) The grosser sort of cinnamon.

DA'RSIS. (From δερω, to excoriate.) An excoriation.

DA'RTOS. (From δερω, to excoriate: so called from its raw and excoriated appearance.) The part so called, under the skin of the scrotum, is by some anatomists considered as a muscle, although it appears to be no more than a condensation of the cellular membrane lining the scrotum. It is by means of the dartos that the skin of the scrotum is corrugated and relaxed.

DARWIN, Erasmus, was born at Elton in Nottinghamshire, in 1731. After studying at Cambridge and Edinburgh, and becoming doctor of medicine, he went to settle at Litchfield. He had soon after the good fortune to succeed in the cure of a gentleman in the neighbourhood, who was so ill of a fever, as to have been given over by the physician previously in attendance: this speedily procured him very extensive practice. He soon after married, and by his first wife had three sons, of whom only one survived him. At the age of 50, he married again, and removed to Derby, where he continued till his death in 1802, leaving six children by his second wife. The active life he led, and his very temperate habits, preserved his health and faculties in a great degree unimpaired. He distinguished himself more as a poet, than by professional improvements: though he certainly suggested some ingenious methods of practice; but, warned by preceding examples, he avoided publishing any material poem, till his medical fame was thoroughly established. His "Botanic Garden," and "Zoonomia," are well known, but they have long ceased to be popular: and the philosophy of the latter work, which advocates materialism, is justly censured. He communicated to the College of Physicians an account of his successful use of digitalis in dropsy, and some other diseases, which was published in their Transactions. His son *Charles*, who died while studying at Edinburgh, obtained a gold medal by an Essay on the distinction of Pus and Mucus; and left another unfinished on the Retrograde Action of the Absorbents: which were published after his death by his father.

Dasy'mna. (From δασυς, rough.) A scabby roughness of the eye-lids.

Da'sys. (Δασυς, rough.) 1. A dry, parched tongue.

2. Difficult respiration.

DATE. See *Dactylus.*

Date plum, Indian. See *Dyospyrus lotus.*

DATOLYTE. Datholit of Werner. A species of silicious ore divided into common datolyte and botroidal datolyte.

DATU'RA. (Blanchard says, it is derived from the Indian word *datiro*, of which he knows not the meaning.) The name of a genus of plants in the Linnæan system. Class, *Pentandria:* Order, *Monogynia.*

Datura stramonium. The systematic name of the thorn-apple. *Stramonium; Dutray; Barryo coccalon; Solanum maniacum* of Dioscorides. *Stramonium spinosum* of Gerard. *Solanum fœtidum* of Bauhin, *Strammonium majus album.* Common thorn-apple. *Datura—pericarpiis spinosis erectis ovatis, foliis ovatis glabris,* of Linnæus. This plant has been long known as a powerful narcotic poison. In its recent state it has a bitterish taste, and a smell somewhat resembling that of poppies, especially if the leaves be rubbed between the fingers. Instances of the deleterious effects of the plant are numerous, more particularly of the seed. An extract prepared from the seeds is recommended by Baron Storck in maniacal, epileptic, and convulsive affections: and is said by some to succeed, while, in the hands of others, it has failed. In this country, says Dr. Woodville, we are unacquainted with any practitioners whose experience tends to throw light on the medical character of this plant. It appears to us, continues Dr. Woodville, that its effects as a medicine are to be referred to no other power than that of a narcotic. And Dr. Cullen, speaking on this subject, says, "I have no doubt that narcotics may be a remedy in certain cases of mania and epilepsy; but I have not, and I doubt if any other person has, learned to distinguish the cases to which such remedies are properly adapted. It is therefore that we find the other narcotics, as well as the stramonium, to fail in the same hands in which they had in other cases seemed to succeed. It is this consideration that has occasioned my neglecting the use of stramonium, and therefore prevented me from speaking more precisely from my own experience on this subject."

The extract of this plant has been the preparation usually employed from one to ten grains and upwards a day; but the powdered leaves, prepared after the manner of those of hemlock, would seem to be more certain and convenient. Greding found the strength of the extract to vary exceedingly; that which he obtained from Ludwig was much more powerful than that which he had of Stoerck. Externally, the leaves of stramonium have been applied to inflammatory tumours and burns, and it is said with success, and of late, the dried leaves have been smoked as a remedy in asthma; but it does not appear that they have been more efficacious in this way than tobacco.

DAUBENTON, Lewis Mary, was born in Burgundy, 1716. Having become doctor in medicine at the age of 24, he went to Paris, and being very zealous in the study of comparative anatomy, the office of keeper of the royal cabinet of natural history was procured for him by the celebrated Buffon. He contributed materially to enrich the splendid work of that eminent naturalist, by furnishing the anatomy both of man and animals. He was a member of several distinguished societies, among others of the Royal Academy of Sciences at Paris, to which he made some useful communications. Having escaped the revolutionary horrors in France, he was chosen, in 1799, a member of the Conservative Senate: but he died towards the end of the same year.

Dauc'ites vinum. Wild carrot-seeds steeped in must.

DAU'CUS. (Απο του δαυειν, from its relieving the colic, and discussing flatulencies.) The carrot. 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Dygynia.*

2. The pharmacopœial name of the garden carrot. See *Daucus carota.*

Daucus alsaticus. The *Oreoselinum pratense* of Linnæus.

Daucus annuus minor. The *Caucalis anthriscus* of Linnæus.

Daucus carota. The systematic name of the carrot plant. *Daucus; Daucus sylvestris; Pastinaca sylvestris tenuifolia officinarum; Daucus—seminibus hispidis, petiolis subtus nervosis* of Linnæus. The cultivated root, scraped and applied in the form of a poultice, is an useful application to phagedænic ulcers, and to cancers and putrid sores. The seeds, which obtain a place in the materia medica, have a light aromatic smell, and a warm acrid taste, and are esteemed for their diuretic qualities, and for their utility in calculous and nephritic complaints, in which an infusion of three spoonfuls of the seeds in a pint of boiling water has been recommended; or the seeds may be fermented in malt liquor, which receives from them an agreeable flavour, resembling that of lemon peel. The boiled root is said by many to be difficult of digestion; but this is the case only when the stomach is weak. It contains a considerable quantity of the saccharine principle, and is very nutritious.

Daucus creticus. See *Athamanta cretensis.*

Daucus sativus. A variety of the *Daucus carota*, the seeds of which are preferred by some practitioners.

Daucus seprinius. Common chervil.

Daucus sylvestris. Wild carrot, or bird's nest. The seeds of the wild plant are said to be more efficacious than those of the garden carrot; they possess demulcent and aromatic qualities, and are given, in infusion, or decoction, in calculous complaints.

DAY-MARE. See *Ephialtes.*

DAY-SIGHT. See *Paropsis noctifuga.*

Dead nettle. See *Lamium album.*

Deadly nightshade. See *Atropa Belladonna.*

DEAFNESS. *Surditas.* See *Paracusis.*

Deaf-dumbness. Speechlessness, from deafness.

Dearticula′tio. (From *de*, and *articulus*, a joint.) Articulation admitting evident motion.

Deascia′tio. (From *de*, and *ascio*, to chip, as with a hatchet.) A bone splintered on its side.

DECAGY′NIA. (From δεκα, ten, and γυνη, a woman.) The name of an order of the class *Decandria*, of the sexual system of plants. See *Plants.*

Decamy′ron. (From δεκα, ten, and μυρον, an ointment.) An aromatic ointment, mentioned by Oribasius, containing ten ingredients.

DECA′NDRIA. (From δεκα, ten, and ανηρ, a man.) The name of a class, and also of an order of plants in the sexual system. See *Plants.*

Decide′ntia. (From *decido*, to fall down.) Any change prolonging acute diseases.

DECI′DUA. (*Deciduus; from decido*, to fall off.) *Membrana decidua.* A very thin and delicate membrane or tunic, which adheres to the gravid uterus, and is said to be a reflection of the chorion, and, on that account, is called *decidua reflexa.* The tunica decidua comes away after delivery, in small pieces, mixed with the *lochia.*

DECI′DUUS. (From *decido*, to fall off, or down: to die.) Deciduous; falling off. Applied to trees and shrubs, which, in most European countries, lose their leaves as winter approaches, and to the *perianthum* of *Tilia europæa*, which does not fall off until after the flower is expanded.

This term is expressive of the second stage of duration, and, like *caducous*, has a different application according to the particular part to which it refers: thus leaves are deciduous which drop off in the autumn, petals which fall off with the stamina and pistils; and calyces are *deciduous* which fall off after the expansion, and before the dropping of the flower.

DECIMA′NUS. (From *decem*, ten, and *mane*, the morning.) Returning every tenth day, applied to some erratic fevers.

DECLI′VIS. (From *de*, and *clivis* a hill.) Declining, descending. A name of an abdominal muscle, because of its posture.

DECO′CTUM. (From *decoquo*, to boil.) A decoction. Any medicine made by boiling in a watery fluid. In a chemical point of view, it is a continued ebullition with water, to separate such parts of bodies as are only soluble at that degree of heat. The following are among the most approved decoctions.

Decoctum album. See *Mistura cornu usti.*

Decoctum aloes compositum. Compound decoction of aloes. Take of extract of liquorice, half an ounce; subcarbonate of potassa, two scruples; extract of spiked aloe powdered, myrrh powdered, saffron stigmata, of each a drachm; water, a pint. Boil down to twelve fluid ounces, and strain; then add compound tincture of cardamoms, four fluid ounces. This decoction now first introduced into the London Pharmacopœia, is analogous to an article in very frequent use, invented by the late Dr. Devalingin, and sold under the name of *Beaume de vie.* By the proportion of tincture which is added, it will keep unchanged for any length of time.

Decoctum althææ. Decoction of marsh mallows. Take of dried marsh mallow roots, ℥iv; raisins of the sun stoned, ℥jj; water ℔vjj. Boil to five pounds; place apart the strained liquor, till the fæces have subsided, then pour off the clear part. This preparation, directed in the Edinburgh Pharmacopœia, may be exhibited as a common drink in nephralgia, and many diseases of the urinary passages, with advantage.

Decoctum anthemidis. See *Decoctum chamæmeli.*

Decoctum astragali. Take of the root of the astragalus escapus, ℥j; distilled water, ℔jjj. These are to be boiled, till only a quart of fluid remain. The whole is to be taken, a little warmed, in the course of 24 hours. This remedy was tried very extensively in Germany, and said to evince very powerful effects, as an antisyphilitic.

Decoctum bardanæ. Take of bardana root, ℥vj; of distilled water, ℔vj. These are to be boiled till only two quarts remain. From a pint to a quart in a day is given, in those cases where sarsaparilla and other remedies that are called alterative are supposed to be requisite.

Decoctum chamæmeli. Chamomile decoction. Take of Chamomile flowers, ℥j; caraway seeds, ℥ss; water, ℔v. Boil fifteen minutes, and strain. A very common and excellent vehicle for tonic powders, pills, &c. It is also in frequent use for fomentation and clysters.

Decoctum cinchonæ. Decoction of cinchona, commonly called decoction of Peruvian bark. Take of lance-leaved cinchona bark bruised, an ounce; water, a pint. Boil for ten minutes, in a vessel slightly covered, and strain the decoction while hot. According to the option of the practitioner, the bark of either of the other species of cinchona, the cordifolia, or *yellow*, or the oblongifolia, or *red*, may be substituted for the lancifolia, or *quilled;* which is here directed. This way of administering the bark is very general, as all the other preparations may be mixed with it, as necessity requires. It is a very proper fomentation for prolapsus of the uterus and rectum.

Decoctum cornu. See *Mistura cornu usti.*

Decoctum cydoniæ. *Mucilago seminis cydonii malii. Mucilago seminum cydoniorum.* Decoction of quince seeds. Take of quince seeds, two drachms; water, a pint. Boil over a gentle fire for ten minutes, then strain. This decoction, in the new London Pharmacopœia, has been removed from among the mucilages, as being less dense than either of the others, and as being employed in larger doses, like other mucilaginous decoctions. In addition to gum, it contains other constituent parts of the seeds, and is therefore, more apt to spoil than common mucilage, over which it possesses no other advantages, than that it is more grateful, and sufficiently thin, without further dilution, to form the bulk of any liquid medicine. Its virtues are demulcent. Joined with syrup of mulberry and a little borax, it is useful against aphthæ of the mouth and fauces.

Decoctum daphnes mezerei. Decoction of mezereon. Take of the bark of mezereon root, ℥ij; liquorice root bruised, ℥ss; water, ℔iij. Boil it, with a gentle heat, down to two pounds, and strain it. From four to eight ounces of this decoction may be given four times a day, in some obstinate venereal and rheumatic affections. It operates chiefly by perspiration.

Decoctum dulcamaræ. Decoction of woody nightshade. Take of woody nightshade stalks, newly gathered, ℥j; distilled water, ℔jss. These are to be boiled away to a pint, and strained. The dose is half an ounce to two ounces, mixed with an equal quantity of milk. This remedy is employed in inveterate cases of scrophula; in cancer and phagedæna; in lepra and other cutaneous affections; and in anomalous local diseases, originating in venereal lues.

Decoctum geoffrææ inermis. Decoction of cabbage-tree plant. Take of bark of the cabbage-tree, powdered, ℥j; water, ℔ij. Boil it, with a gentle fire, down to one pound, and strain. This is a powerful anthelmintic. It may be given in doses of one table-spoonful to children, and four to adults. If disagreeable symptoms should arise from an over-dose, or from drinking cold water during its action, we must immediately purge with castor-oil, and dilute with acidulated drinks.

Decoctum guaiaci officinalis compositum. *Decoctum lignorum.* Compound decoction of guaiacum, commonly called decoction of the woods. Take of guaiacum raspings, ℥iij: raisins stoned, ℥ij; sassafras root, liquorice, each ℥j; water, ℔x. Boil the guaiacum and raisins with the water, over a gentle fire, to the consumption of one-half; adding, towards the end, the sassafras and liquorice. Strain the liquor without expression. This decoction possesses stimulant and diaphoretic qualities, and is generally exhibited in rheumatic and cutaneous diseases, which are dependent on a vitiated state of the humours. It may be taken by itself, to the quantity of a quarter of a pint, twice or thrice a day, or used as an assistant in a course of mercurial or antimonial alteratives; the patient, in either case, keeping warm, in order to promote the operation of the medicine.

Decoctum hellebori albi. Decoction of white hellebore. Take of the root of white hellebore powdered, by weight ℥j; water, two pints; rectified spirits of wine ℥ij by measure. Boil the water, with the root, to one pint; and the liquor being cold and strained, add to it the spirit. This decoction, in the last London Pharmacopœia, is called decoctum veratri. It is a very efficacious application, externally, as a wash, in tinea capitis, lepra, psora, &c. When the skin is very tender and irritable, it should be diluted with an equal quantity of water.

Decoctum hordei. *Decoctum hordei distichi. Aqua hordeata.* Take of pearl barley, ℥ij; water, four pints and a half. First wash away any adhering extraneous substances with cold water; next, having poured upon the barley half a pint of water, boil for a few minutes. Let this water be thrown away, and add the remainder of the water boiling; then boil down to two pints and strain. Barley-water is a nutritive and softening drink, and the most proper of all liquors in inflammatory diseases. It is an excellent gargle in inflammatory sore throats, mixed with a little nitre.

Decoctum hordei compositum. *Decoctum pectorale.* Compound decoction of barley. Take of decoction of barley, two pints; figs sliced, ℥ij; liquorice root, sliced and bruised, ℥ss; raisins stoned, ℥ij; water, a pint. Boil down to two pints, and strain. From the pectoral and demulcent qualities of this decoction, it may be administered as a common drink in fevers and other acute disorders, in catarrh, and several affections of the chest.

Decoctum hordei cum gummi. Barley water, ℔ij; gum arab. ℥j. The gum is to be dissolved in the barley decoction whilst warm. It then forms a suitable diluent in strangury, dysury, &c. for the gum, finding a passage into the bladder in an unaltered state, mixes with the urine, and prevents the action of its neutral salts on the urinary canal.

Decoctum lichenis. Decoction of Iceland moss or liverwort. Take of liverwort, one ounce: water a pint and a half. Boil down to a pint and strain. The dose is from ℥j to ℥iv.

Decoctum lobeliæ. Take a handful of the roots of the *Lobelia sphilitica;* distilled water, ℔xij. These are to be boiled in the usual way, till only four quarts remain. The very desirable property of curing the venereal disease has been attributed to this medicine; but it is not more to be depended on than guaiacum, or other vegetable substances, of which the same thing has been alleged. The effects of this decoction are purgative, and the manner of taking it, as described by Swediaur, is as follows:—The patient is to begin with half a pint twice a day. The same quantity is then to be taken four times a day, and continued so long as its purgative effect is not too considerable. When the case is otherwise, it is to be discontinued for three or four days, and then had recourse to again till the cure is completed. As this is a remedy on the old system, and not admitted into our pharmacopœias, little confidence ought to be placed in it.

Decoctum lusitanicum. Take of sliced sarsaparilla, lignum sassafras, lignum santalum rubrum, officinal lignum guaiacum, of each one ounce and a half; of the root of mezereon, coriander seed, of each half an ounce; distilled water, ten pounds. These are to be boiled till only half the fluid remains. The dose is a quart or more in a day.

Take of sliced sarsaparilla, lignum santalum rubrum, lignum santalum citrinum, of each ℥jss; of the root of glycyrrhiza and mezereon, of each ʒij; of lignum rhodii, officinal lignum guaiacum, and lignum sassafras, of each ℥ss; of antimony, ℥j; distilled water, ℔v. These ingredients are to be macerated for twenty-four hours, and afterwards boiled, till the fluid is reduced to half its original quantity. From one to four pints are given daily.

The late Mr. Hunter notices this, and also the following formula, in his treatise on the Venereal Disease.

Take of sliced sarsaparilla, of the root of China, of each ℥j; walnut peels dried, xx; antimony, jj℥; pumice-stone, powdered ℥j; distilled water, ℔x. The powdered antimony and pumice-stone are to be tied in separate pieces of rag, and boiled, along with the other ingredients. This last decoction is reckoned to be the genuine Lisbon diet drink, the qualities of which have been the subject of so much encomium.

Decoctum malvæ compositum. *Decoctum pro enemate. Decoctum commune pro clystere.* Compound decoction of mallows. Take of mallows dried, an ounce; chamomile flowers dried, half an ounce; water, a pint. Boil for a quarter of an hour, and strain. A very excellent form for an emollient clyster. A variety of medicines may be added to answer particular indications.

Decoctum mezerei. See *Decoctum daphnes mezerei.*

Decoctum papaveris. *Decoctum pro fomento. Fotus communis.* Decoction of poppy. Take of white poppy capsules bruised, ℥iv; water, four pints. Boil for a quarter of an hour, and strain. This preparation possesses sedative and antiseptic properties, and may be directed with advantage in sphacelus, &c.

Decoctum pro enemate. See *Decoctum malvæ compositum.*

Decoctum pro fomento. See *Decoctum papaveris.*

Decoctum quercus. Decoction of oak bark. Take of oak bark, ℥j; water, two pints. Boil down to a pint, and strain. This astringent decoction has lately been added to the Lond. Pharm. and is chiefly used for external purposes. It is a good remedy in prolapsus ani, and may be used also in some cases as an injection.

Decoctum sarsaparillæ. Decoction of sarsaparilla. Take of sarsaparilla root, sliced, ℥iv; boiling water, four pints. Macerate for four hours, in a vessel lightly covered, near the fire; then take out the sarsaparilla and bruise it. After it is bruised, put it again into the liquor, and macerate it in a similar manner for two hours more; then boil it down to two pints, and strain.

This decoction is much extolled by some practitioners, in phthisis, and to restore the strength after a long course of mercury.

Decoctum sarsaparillæ compositum. Compound decoction of sarsaparilla. Take of decoction of sarsaparilla boiling, four pints; sassafras root sliced, guaiacum wood shavings, liquorice root bruised, of each an ounce; mezereon root bark, ʒiij. Boil for a quarter of an hour, and strain. The alterative property of the compound is very great; it is generally given after a course of mercury, where there have been nodes and indolent ulcerations, and with great benefit. The dose is from half a pint to a pint in twenty-four hours.

Decoctum senegæ. Decoction of senega. Take of senega root, ℥j; water, two pints. Boil down to a pint, and strain. This is now first introduced into the Lond. Pharm. as being a useful medicine, especially in affections of the lungs, attended with debility and inordinate secretion.

Decoctum ulmi. Decoction of elm bark. Take of fresh elm bark bruised, four ounces; water, four pints. Boil down to two pints, and strain. This may be employed with great advantage as a collyrium in chronic ophthalmia. It is given internally in some cutaneous eruptions.

Decoctum veratri. See *Decoctum hellebori albi.*

DECOLLA'TIO. (From *decollo*, to behead.) The loss of a part of the skull.

Decompositæ. The name of a class in Sauvage's Methodus Foliorum, consisting of such as have twice compounded leaves; that is, have a common footstalk supporting a number of lesser leaves, each of which is compounded; as in *Fumaria*, and many umbelliferous plants.

DECOMPOSITION. *Decompositio.* The separation of the component parts or principles of bodies from each other. The decomposition of bodies forms a very large part of chemical science. It seems probable, from the operations we are acquainted with, that it seldom takes place but in consequence of some combinations or composition having been effected. It would be difficult to point out an instance of the separation of any of the principles of bodies which has been effected unless in consequence of some new combination. The only exceptions seem to consist in those separations which are made by heat, and voltaic electricity.

DECOMPOSITUS. A term applied to leaves, and means doubly compound. Sir James Smith observes, that Linnæus, in his Philosophia Botanica, gives an erroneous definition of this term, which does not agree with his own use of it. The *Ægopodium podagraria* and *Fulmaria claviculata*, afford examples of the decomposite leaves. *Supra decompositum*, means thrice compound, or more; as in *Caucalis anthriscus.* The decomposite flowers are such as contain within a common calyx a number of lesser or partial flower-cups, each of which is composed of many florets.

DECORTICATION. (*Decorticatio;* from *de*, from, and *cortex*, bark.) The stripping of any thing of its bark, husk, or shell: thus almonds, and the like, are decorticated, that is, deprived of their pellicle, when ordered for medicinal purposes.

DECREPITATION. (*Decrepitatio;* from *decrepo*, to crackle.) A kind of crackling noise, which takes place in some bodies, when heated: it is peculiar to some kinds of salts, as muriate of soda, sulphate of barytes, &c.

DECUMBENS. (From *decumbo*, to lie down.) Drooping: a term applied to flowers which incline to one side and downwards.

DECURRENS. Decurrent. A term applied by botanists to leaves which run down the stem or leafy border or wing; as in *Onopordium acanthium*, and many thistles, great mullein, and comfrey: and to leaf-stalks; as in *Pisum ochrus.*

DECURSIVE. Decurrently. Applied to leaflets that run down the stem; as in *Eryngium campestre.*

DECUSSATION. (*Decussatio;* from *decutio*, to divide.) When nerves, or muscular fibres cross one another, they are said to decussate each other.

DECUSSATUS. Decussated. Applied to leaves and spines which are in pairs, alternately crossing each other; as in *Veronica decussata*, and *Genista lucitanica.*

DECUSSO'RIUM. (From *decusso*, to divide.) An instrument to depress the dura mater, after trepanning.

Defensi'va. (From *defendo*, to preserve.) Cordial medicines, or such as resist infection.

DE'FERENS. (From *defero*, to convey; because it conveys the seamen to the vesiculæ seminales.) See *Vas deferens.*

DEFLAGRATION. (*Deflagratio;* from *deflagro*, to burn.) A chemical term, chiefly employed to express the burning or setting fire to any substance; as nitre, sulphur, &c.

DEFLUXION. (*Defluxio;* from *defluo*, to run off.) A falling down of humours from a superior to an inferior part. Many writers mean nothing more by it than inflammation.

DEFOLIATIO. (From *de*, and *folium*, a leaf.) The fall of the leaf. A term opposed to *frondescentia*, or the renovation of the leaf.

DEGLUTITION. (*Deglutitio;* from *deglu-*

tio, to swallow down.) A natural action. "It is understood to be the passage of a substance, either solid, liquid, or gaseous from the mouth to the stomach. Though deglutition is very simple in appearance, it is nevertheless the most complicated of all the muscular actions that serve for digestion. It is produced by the contraction of a great number of muscles, and requires the concurrence of many important organs.

All the muscles of the tongue, those of the *velum* of the palate, of the pharynx, of the larynx, and the muscular layer of the œsophagus, are employed in deglutition.

The *velum* is a sort of valve attached to the posterior edge of the roof of the palate; its form is nearly quadrilateral; its free or inferior edge is pointed, and forms the *uvula*. Like the other valves of the intestinal canal, the *velum* is essentially formed by a duplicature of the digestive mucous membrane; there are many mucous follicles that enter into its composition, particularly in the uvula. Eight muscles move it; it is raised by the two internal *pterygoid;* the external *pterygoid* hold it transversely; the two *palato-pharyngei*, and the two *constrictores isthmi faucium* carry it downwards. These four are seen at the bottom of the throat, where they raise the mucous membrane, and form the pillars of the *velum* of the palate, between which are situated the *amygdalæ*, a mass of mucous follicles. The opening between the base of the tongue below, the *velum* of the palate above, and the pillars laterally, is called the isthmus of the throat. By means of its muscular apparatus, the *velum* of the palate may have many changes of position. In the most common state it is placed vertically, one of its faces is anterior, the other posterior; in certain cases it becomes horizontal: it has then a superior and inferior aspect, and its free edge corresponds to the concavity of the pharynx. This last position is determined by the contraction of the elevating muscles.

The *pharynx* is a vestibule into which open the nostrils, the Eustachian tubes, the mouth, the larynx, and the œsophagus, and which performs very important functions in the production of voice, in respiration, hearing and digestion.

The pharynx extends from top to bottom, from the basilar process of the occipital bone, to which it is attached, to the level of the middle part of the neck.

Its transverse dimensions are determined by the os hyoides, the larynx and the pterygo-maxillary aponeurosis, to which it is fixed. The mucous membrane which covers it interiorly is remarkable for the developement of its veins, which form a very apparent plexus. Round this membrane is the muscular layer, the circular fibres of which form the three constrictor muscles of the pharynx, the longitudinal fibres of which are represented by the stylo-pharyngeus and constrictores isthmi faucium. The contractions of these different muscles are not generally subject to the will.

The *œsophagus* is the immediate continuation of the pharynx, and is prolonged as far as the stomach, where it terminates. Its form is cylindrical; it is united to the surrounding parts by a slack and extending cellular tissue, which gives way to its dilatation and its motions. To penetrate into the abdomen the œsophagus passes between the pillars of the diaphragm, with which it is closely united. The mucous membrane of the œsophagus is white, thin, and smooth; it forms longitudinal folds very proper for favouring the dilatation of the canal. Above it is confounded with that of the pharynx.

There are found in it a great number of mucous follicles, and at its surface there are perceived the orifices of many excretive canals of the mucous glands.

The muscular layer of the œsophagus is thick, its tissue is denser than that of the pharynx; the longitudinal fibres are the most external and the least numerous; the circular are placed in the interior and are very numerous.

Round the pectoral and inferior portion of the œsophagus, the two nerves of the eighth pair form a plexus, which embraces the canal, and sends many filaments into it.

The contraction of the œsophagus takes place without the participation of the will.

Mechanism of Deglutition. Deglutition is divided into three periods. In the first, the food passes from the mouth to the pharynx; in the second, it passes the opening of the glottis, that of the nasal canals, and arrives at the œsophagus; in the third it passes through this tube and enters the stomach.

Let us suppose the most common case, that in which we swallow at several times the food which is in the mouth, and according as mastication takes place.

As soon as a certain quantity of food is sufficiently chewed, it is placed, by the effects of the motions of mastication, in part upon the superior face of the tongue, without the necessity, as some think, of its being collected by the point of the tongue from the different parts of the mouth. Mastication then stops; the tongue is raised and applied to the roof of the palate, in succession, from the point towards the base. The portion of food, or the alimentary bolus placed upon its superior surface, having no other way to escape from the force that presses, is directed towards the pharynx; it soon meets the velum of the palate applied to the base of the tongue and raises it; the velum becomes horizontal, so as to make a continuation of the palate. The tongue, continuing to press the food, would carry it towards the nasal canals, if the velum did not prevent this by the tension that it receives from the external peristaphyline muscles, and particularly by the contraction of its pillars; it thus becomes capable of resisting the action of the tongue, and of contributing to the direction of the food towards the pharynx.

The muscles which determine more particularly the application of the tongue to the top of the palate, and to the velum of the palate, are the proper muscles of the organ, aided by the mylo-hyoideus. Here the first time of deglutition terminates. Its motions are voluntary, except those of the velum of the palate. The phenomena happen slowly and in succession; they are few and easily noticed.

The second period is not the same; in it the phenomena are simultaneous, multiplied, and are produced with such promptitude that Boerhaave considered them as a sort of convulsion.

The space that the alimentary bolus passes through in this time is very short, for it passes only from the middle to the inferior part of the pharynx; but it was necessary to avoid the opening of the glottis, and that of the nasal canals, where its presence would be injurious. Besides, its passage ought to be sufficiently rapid in order that the communication between the larynx and the external air may not be interrupted, except for an instant.

Let us see how nature has arrived at this important result. The alimentary bole no sooner touches the pharynx than every thing is in motion. First, the pharynx contracts, embraces and retains the bole; the velum of the palate, drawn down by its pillars, acts in the same way. On the other hand, and in the same instant, the base of the tongue, the os hyoides, the larynx, are raised and carried forward to meet the bole, in order to render its passage more rapid over the opening of the glottis. Whilst the os hyoides and the larynx are raised, they approach each other, that is, the superior edge of the thyroid cartilage engages itself behind the body of the os hyoides: the epiglottic gland is pushed back; the epiglottis descends, inclines downwards and backwards, so as to cover the entrance of the larynx. The cricoid cartilage makes a motion of rotation upon the inferior horns of the thyroid, whence it results that the entrance of the larynx becomes oblique downwards and backwards. The bole slides along its surface, and being always pressed by the contraction of the pharynx and of the velum of the palate, it arrives at the œsophagus.

It is not long since the position that the epiglottis takes in this case was considered as the only obstacle opposed to the entrance of the food into the larynx, at the instant of deglutition; but Dr. Magendie has shown, by a series of experiments, that this cause ought to be considered as only accessary. In fact, the epiglottis may be entirely taken away from an animal, without deglutition suffering any injury from it. What is the reason, then, that no part of the food is introduced into the larynx the instant that we swallow? The reason is this. In the instant that the larynx is raised and engaged behind the os hyoides, the glottis shuts with the greatest closeness. This motion is produced by the same muscles that press the glottis in the production of the voice; so that if an animal has the recurrents and nerves of the larynx divided, whilst the epiglottis is untouched, its deglutition is rendered very difficult, because the principal cause is removed which opposes the introduction of food into the glottis.

Immediately after the alimentary bole has passed the glottis, the larynx descends, the epiglottis is raised, and the glottis is opened to give passage to the air.

After what has been said, it is easy to conceive why the food reaches the œsophagus without entering any of the openings which end in the pharynx. The velum of the palate, which, in contracting, embraces the pharynx, protects the posterior nostrils and the orifices of the Eustachian tubes; the epiglottis, and particularly the motion by which the glottis shuts, preserves the larynx.

Thus, the second period of deglutition is accomplished; by the effects of which the alimentary bole passes the pharynx, and is engaged in the superior part of the œsophagus. All the phenomena which concur in it take place simultaneously, and with great promptitude: they are not subject to the will; they are then different in many respects from the phenomena that belong to the first period.

The third period of deglutition is that which has been studied with the least care, probably on account of the situation of the œsophagus, which is difficult to be observed except in its cervical portion.

The phenomena which are connected with it are not complicated. The pharynx, by its contraction, presses the alimentary bole into the œsophagus with sufficient force to give a suitable dilatation to the superior part of this organ. Excited by the presence of the bolus, its superior circular fibres very soon contract, and press the food towards the stomach, thereby producing the distension of those more inferior. These contract in their turn, and the same thing continues in succession until the bolus arrives at the stomach. In the upper two-thirds of the œsophagus, the relaxation of circular fibres follows immediately the contraction by which they displaced the alimentary bolus. It is not the same with the inferior third; this remains some moments contracted after the introduction of food into the stomach.

All the extent of the mucous surface that the alimentary bolus passes in the three periods of deglutition is lubricated by an abundant mucosity. In the way that the bolus passes, it presses more or less the follicles that it meets in its passage, it empties them of the fluid that they contain, and slides more easily upon the mucous membrane. We remark that in those places where the bolus passes more rapidly, and is pressed with greater force, the organs for secreting mucus are much more abundant. For example, in the narrow space where the second period of deglutition takes place, there are found the tonsils, the fungous papillæ of the base of the tongue, the follicles of the velum of the palate, and the uvula, those of the epiglottis, and the arytenoid glands. In this case the saliva and the mucosity fulfil uses analogous to those of the synovia.

The mechanism by which we swallow the succeeding mouthfuls of food does not differ from that which we have explained.

Nothing is more easy than the performance of deglutition, and, nevertheless, all the acts of which it is composed are beyond the influence of the will and of instinct. We cannot make an empty motion of deglutition. If the substance contained in the mouth is not sufficiently chewed, if it has not the form, the consistence, and the dimensions of the alimentary bolus, if the motions of mastication which immediately precede deglutition have not been made, we will frequently find it impossible to swallow it, whatever efforts we make. How many people do we not find who cannot swallow a pill, or medicinal bolus, and who are obliged to fall upon other methods to introduce it into the œsophagus?"—*Magendie.*

DE′GMUS. (From δακνω, to bite.) A biting pain in the orifice of the stomach.

DEHISCENTIA. (From *dehisco*, to gape wide.) A spitting, or bursting open. Applied to capsules, anthers, &c. of plants.

DEIDIER, ANTHONY, was son of a surgeon of Montpelier. Having graduated in medicine in 1691, he was six years after made professor of chemistry. In 1732, being appointed physician to the galleys, he went to Marseilles, where he died in 1746. He published among many other works on different branches of medicine, "Experiments on the Bile, and the Bodies of those who died of the Plague," which occurred while he was at Marseilles. He states that he tried mercurial inunctions, but they had no effect on the disease. There are three volumes of consultations and observations by him deserving of perusal. The rest of his works are scarcely now referred to.

DEINO′SIS. (From δεινοω, to exaggerate.) An enlargement of the supercilia.

DEJE′CTIO. A discharge of any excrementitious matter; generally applied to the fæces: hence *dejectio alvina.*

DEJECTO′RIA. (From *dejicio*, to cast out.) Purging medicines.

DELACHRYMATI′VA. (From *de*, and *lachryma*, a tear.) Medicines which dry the eyes, first purging them of tears.

DELA′PSIO. (From *delabor*, to slip down.) A falling down of any part, as the anus, uterus, or intestines.

DELETERIOUS. (*Deleterius;* from δηλεω, to hurt or injure.) Of a poisonous nature; as opium, hemlock, henbane, &c.

DELIQUESCENCE. Deliquation, or the spontaneous assumption of the fluid state of certain saline bodies, when left exposed to the air, in consequence of their attracting water from it.

DELI'QUIUM. (*Deliquium*; from *delinquo*, to leave.) A fainting. See *Syncope*.

DELI'RIUM. (From *deliro*, to rave.) A febrile symptom, consisting in the person's acting or talking unreasonably. It is to be carefully distinguished from an alienation of the mind, without fever.

DELIVERY. See *Parturition*.

Deloca'tio. (From *de*, from, and *locus*, a place.) A dislocation.

DELPHIA. See *Delphinia*.

DELPHINE. See *Delphinia*.

DELPHINIA. *Delphia.* Delphine. A new vegetable alkali, recently discovered by Lasseigne and Feneulle, in Stavesacre. See *Delphinium staphysagria*.

DELPHINIC ACID. *Acidum delphinicum.* The name of an acid, extracted from the oil of the dolphin. It resembles a volatile oil; has a light lemon colour, and a strong aromatic odour, analogous to that of rancid butter. Its taste is pungent, and its vapour has a sweetened taste of æther. It is slightly soluble in water, and very soluble in alkohol. The latter solution strongly reddens litmus. 100 parts of delphinic acid neutralise a quantity of base, which contains 9 of oxygen, whence its prime equivalent appears to be 11.11.

DELPHINITE. See *Epidote*.

DELPHI'NIUM. (From δελφινος, the dolphin.) Larkspur; so called from the likeness of its flower to the dolphin's head. The name of a genus of plants in the Linnæan system. Class, *Polyandria*; Order, *Trigynia*.

Delphinium consolida. The systematic name of the *Consolida regalis*. *Calcatrippa*. *Delphinium—nectariis monophyllis, caule subdiviso*, of Linnæus. Many virtues have been attributed to this plant. The flowers are bitter, and a water distilled from them is recommended in ophthalmia. The herb has been administered in calculous cases, obstructed menses, and visceral diseases.

Delphinium staphisagria. The systematic name of stavesacre. *Staphisagria*; *Staphis*; *Pedicularia*; *Delphinium—nectariis tetraphyllis petalo brevioribus, foliis palmatis, lobis obtusis*, of Linnæus. The seeds, which are the only parts directed for medicinal use, are usually imported here from Italy; they are large, rough, of an irregular triangular figure, and of a blackish colour on the outside, but yellowish within; their smell is disagreeable, and somewhat fœtid; to the taste they are very bitter, acrid, and nauseous. It was formerly employed as a masticatory, but is now confined to external use, in some kinds of cutaneous eruptions, but more especially for destroying lice and other insects: hence, by the vulgar, it is called louse-wort.

A new vegetable alkali has lately been discovered in this plant by Lasseigne and Feneulle. It is thus obtained:

The seeds, deprived of their husks, and ground, are to be boiled in a small quantity of distilled water, and then pressed in a cloth. The decoction is to be filtered, and boiled for a few minutes with pure magnesia. It must then be re-filtered, and the residuum left on the filter is to be well washed, and then boiled with highly rectified alkohol, which dissolves out the alkali. By evaporation, white pulverulent substance, presenting a few crystalline points, is obtained.

It may also be procured by the action of dilute sulphuric acid, on the bruised but unshelled seeds. The solution of sulphate thus formed, is precipitated by subcarbonate of potassa. Alkohol separates from this precipitate the vegetable alklali in an impure state.

Pure delphinia obtained by the first process, is crystalline while wet, but becomes opake on exposure to air. Its taste is bitter and acrid. When heated it melts; and on cooling becomes hard and brittle like resin. If more highly heated, it blackens and is decomposed. Water dissolves a very small portion of it. Alkohol and æther dissolve it very readily. The alkoholic solution renders syrup of violets green, and restores the blue tint of litmus reddened by an acid. It forms soluble neutral salts with acids. Alkalies precipitate the delphinia in a white gelatinous state, like alumina.

Sulphate of delphinia evaporates in the air, does not crystallise, but becomes a transparent mass like gum. It dissolves in alkohol and water, and its solution has a bitter acrid taste. In the voltaic circuit it is decomposed, giving up its alkali at the negative pole.

Nitrate of delphinia, when evaporated to dryness, is a yellow crystalline mass. If treated with excess of nitric acid, it becomes converted into a yellow matter, little soluble in water, but soluble in boiling alkohol. This solution is bitter, is not precipitated by potassa, ammonia, or lime-water, and appears to contain no nitric acid, though itself is not alkaline. It is not destroyed by further quantities of acid, nor does it form oxalic acid. Strychnia and morphia take a red colour from nitric acid, but delphinia never does. The muriate is very soluble in water.

The acetate of delphinia does not crystallise, but forms a hard transparent mass, bitter and acrid, and readily decomposed by cold sulphuric acid. The oxalate forms small white plates, resembling in taste the preceding salts.

Delphinia, calcined with oxide of copper, gave no other gas than carbonic acid. It exists in the seeds of the stavesacre, in combination with malic acid, and associated with the following principles: 1. A brown bitter principle, precipitable by acetate of lead. 2. Volatile oil. 3. Fixed oil. 4. Albumen. 5. Animalised matter. 6. Mucus. 7. Saccharine mucus. 8. Yellow bitter principle, not precipitable by acetate of lead. 9. Mineral salts.—*Annales de Chimie et de Physique*, vol. xii. p. 358.

DE'LPHYS. Δελφυς. The uterus, or pudendum muliebre.

DE'LTA. (The Greek letter Δ.) The external pudendum muliebre is so called, from the triangular shape of its hair.

DELTOI'DES. (From δελτα, the Greek letter Δ, and ειδος, a likeness; shaped like the Greek delta.) 1. A muscle of the superior extremity, situated on the shoulder. *Sous-acromio-clavihumeral* of Dumas. It arises exactly opposite to the trapezius, from one-third part of the clavicle, from the acromion and spine of the scapula, and is inserted, tendinous, into the middle of the os humeri, which bone it lifts up directly; and it assists with the supraspinatus and coracobrachialis in all the actions of the humerus, except the depression; it being convenient that the arm should be raised and sustained, in order to its moving on any side.

2. A leaf is so called, *folium deltoides*, which is trowel-shaped, or like the letter delta, having

three angles, of which the terminal one is much further from the base than the lateral ones; as in *Chenopodium bonus-henricus.*

DEME'NTIA. (From *de*, and *mens*, without mind.) Absence of intellect; madness; fatuity.

DEMERSUS. A leaf which is naturally under water, and different from those above, is so called; *folia immersa*, and *submersa*, are the same as *demersa*. See *Natans.*

DEMULCENT. (*Demulcens*; from *demulceo*, to soften.) Medicines suited to obviate and prevent the action of acrid and stimulant matters; and that not by correcting or changing their acrimony, but by involving it in a mild and viscid matter, which prevents it from acting upon the sensible parts of our bodies, or by covering the surface exposed to their action.

Where these substances are directly applied to the parts affected, it is easy to perceive how benefit may be derived from their application. But where they are received by the medium of the stomach, into the circulating system, it has been supposed that they can be of no utility, as they must lose that viscidity on which their lubricating quality depends. Hence it has been concluded that they can be of no service in gonorrhœa, and some similar affections. It is certain, however, says J. Murray, in his Elements of Materia Medica and Pharmacy, that many substances which undergo the process of digestion are afterwards separated, in their entire state, from the blood, by particular secreting organs, especially by the kidneys; and it is possible, that mucilaginous substances, which are the principal demulcents, may be separated in this manner. There can be no doubt, however, but that a great share of the relief demulcents afford, in irritation or inflammation of the urinary passages, is owing to the large quantities of water in which they are diffused, by which the urine is rendered less stimulating from dilution. In general, demulcents may be considered merely as substances less stimulating than the fluids usually applied.

Catarrh, diarrhœa, dysentery, calculus, and gonorrhœa, are the diseases in which demulcents are employed. As they are medicines of no great power, they may be taken in as large quantities as the stomach can bear.

The particular demulcents may be reduced to the two divisions of mucilages and expressed oils. The principal demulcents are, the acacia vera, astragalus, tragacanthe, linum usitatissimum, althæa officinalis, malva, sylvestris, glycyrrhiza glabra, cycas circinalis, orchis mascula, maranta arundinacea, triticum hybernum, ichthyocolla, olea Europæa, amygdalus communis, cetaceum, and cera.

DENDROLI'BANUS. (From *δενορον*, a tree, and *ολιβανος*, frankincense.) Frankincense-tree. See *Rosmarinus officinalis.*

DENS. (*Dens, tis.* m.; *quasi edens*; from *edo*, to eat, or from *οδους, οδοντος*.)

1. A tooth. See *Teeth.*

2. Many herbs have this specific name, from their fancied resemblance to the tooth of some animal; as *Dens leonis*, the dandelion; *Dens canis*, dog's tooth, &c.

DENS CANINUS. See *Teeth.*

DENS CUSPIDATUS. See *Teeth.*

DENS INCISOR. See *Teeth.*

DENS LACTEUS. See *Teeth*, and *Dentition.*

DENS LEONIS. See *Leontodon Taraxacum.*

DENS MOLARIS. See *Teeth.*

DENTA'GRA. (*Dentagra, οδονταγρα*; from *οδους*, a tooth, and *αγρα*, a seizure.) 1. The toothache.

2. An instrument for drawing the teeth.

DENTA'RIA. (*Dentaria*; from *dens*, a tooth: so called because its root is denticulated.) See *Plumbago europæa.*

DENTARPA'GA. (From *οδους*, a tooth, and *αρπαζω*, to fasten upon.) An instrument for drawing of teeth.

DENTATA. See *Dentatus.*

DENTA'TUS. (From *dens*, a tooth; from its tooth-like process.) 1. The second vertebra of the neck. *Dentata*; *Epistrophæus.* It differs from the other cervical vertebræ, by having a tooth-like process at the upper part of the body. See *Vertebræ.*

2. Toothed: applied to roots, leaves, petals, &c. which are beset with projecting, horizontal, rather distant teeth of its own substance; as in the leaf of *Atriplex lacinata*, and the perianthium of *Marrubium vulgare*, and *Ereca denticulata*, and the petals of the *Silene lucitanica.* The *Ophris corallorhiza* has a toothed root.

DENTELLA'RIA. (From *dentella*, a little tooth; so called because its root is denticulated.) The herb tooth-wort. See *Plumbago europæa.*

DENTIDU'CUM. (From *dens*, a tooth, and *duco*, to draw.) An instrument for drawing of teeth.

DENTIFRICE. (*Dentifricus*; from *dens*, a tooth, and *frigo*, to rub.) A medicine to clean the teeth.

DENTISCA'LPIUM. (From *dens*, a tooth, and *scalpo*, to scrape.) An instrument for scaling teeth.

DENTITION. (*Dentitio*; from *dentio*, to breed teeth.) *Odontiasis*; *Odontophica.* The breeding or cutting of the teeth. The first dentition begins about the sixth or seventh month, and the teeth are termed the *primary* or *milk* teeth. About the seventh year, these fall out, and are succeeded by others, which remain during life, and are called the *secondary* or *perennial* teeth. The last dentition takes place between the ages of twenty and five-and-twenty, when the four last grinders appear; they are called *dentes sapientiæ.* See also *Teeth.*

DENTODU'CUM. See *Dentiducum.*

DENUDATÆ PLANTÆ. The name of an order of Linnæus's Fragments of a Natural Method, embracing those plants the flowers of which are naked or without a flower-cup.

DENUDA'TIO. (From *denudo*, to make bare.) The laying bare any part; usually applied to a bone.

DENUDATUS. (From *denudo*, to strip naked.) Denude; naked.

DEOBSTRUENT. (*Deobstruens*; from *de*, and *obstruo*, to obstruct.) A medicine that is exhibited with a view of removing any obstruction.

DEOPPILA'NTIA. (From *de*, and *oppilo*, to stop.) *Deoppilativa.* Medicines which remove obstructions.

DEPARTI'TIO. (From *de*, and *partior*, to divide.) Separating metals.

DEPERDI'TIO. (From *deperdo*, to lose.) Abortion, or the undue loss of the fœtus.

DEPETI'GO. (From *de*, and *petigo*, a running scab.) A ring-worm, tetter, scurf, or itch, where the skin is rough.

DEPHLEGMA'TION. (*Dephlegmatio*; from *de*, and *phlegma*, phlegm.) The operation of rectifying or freeing spirits from their watery parts, or any method by which bodies are deprived of their water.

DEPHLOGISTICATED. A term of the old chemistry, implying deprived of phlogiston or the inflammable principle.

Dephlogisticated air. See *Oxygen gas.*

Dephlogisticated muriatic acid. See *Chlorine.*

DEPILATORY. (*Depilatorius*; from *de*, of, and *pilus*, the hair.) Any application which removes the hairs from any part of the body; thus, a pitch cap pulls the hairs of the head out by the roots.

DEPLU'MATIO. (From *de*, and *pluma*, a feather.) A disease of the eyelids, which causes the hair to fall off.

DEPREHE'NSIO. (From *deprehendo*, to catch unawares.) The epilepsy is so called, from the suddenness with which persons are seized with it.

DEPRESSION. (*Depressio*; from *deprimo*, to press down.) When the bones of the skull are forced inwards by fracture, they are said to be depressed.

DEPRE'SSOR. (From *deprimo*, to press down.) A muscle is so termed, which depresses the part on which it acts.

DEPRESSOR ALÆ NASI. See *Depressor labii superioris alæque nasi.*

DEPRESSOR ANGULI ORIS. A muscle of the mouth and lip, situated below the under lip. *Triangularis* of Winslow. *Depressor labiorum communis* of Douglas. *Depressor labiorum* of Cowper. *Sous-maxillo-labial* of Dumas. It arises broad and fleshy, from the lower edge of the lower jaw, near the chin; and is inserted into the angle of the mouth, which it pulls downwards.

DEPRESSOR LABII INFERIORIS. A muscle of the mouth and lip. *Quadratus* of Winslow. *Depressor labii inferioris proprius* of Douglas and Cowper. *Mentonier labial* of Dumas. It pulls the under lip and skin of the side of the chin downwards, and a little outwards.

DEPRESSOR LABII SUPERIORIS ALÆQUE NASI. A muscle of the mouth and lip. *Depressor alæ nasi* of Albinus. *Incisivus medius* of Winslow. *Depressor labii superioris proprius* of Douglas. *Constrictores alarum nasi, ac depressores labii superioris* of Cowper. *Maxillo-alveoli nasal* of Dumas. It is situated above the mouth, draws the upper lip and ala nasi downwards and backwards. It arises, thin and fleshy, from the superior maxillary bone, immediately above the joining of the gums, with the two incisor teeth and cuspidatus; from thence it runs upwards, and is inserted into the upper lip and root of the ala of the nose.

DEPRESSOR LABII SUPERIORIS PROPRIUS. See *Depressor labii superioris alæque nasi.*

DEPRESSOR LABIORUM COMMUNIS. See *Depressor anguli oris.*

DEPRESSOR OCULI. See *Rectus inferior oculi.*

DEPRESSUS. Depressed; flattened vertically, as the leaves of the *Mesembryanthemum linguiforme. Folia depressa* is applied also to radical leaves which are pressed close to the ground, as is seen in *Plantago media*; but when applied to stem leaves, it regards their shape only, as being vertically flattened in opposition to *compressa.*

DE'PRIMENS. See *Rectus inferior oculi.*

DEPURA'NTIA. (*Depurans*; from *depuro*, to make clean.) Medicines which evacuate impurities.

DEPURA'TION. *Depuratio.* The freeing a liquor or solid from its foulness.

DEPURATO'RIUS. (From *de*, and *purus*, pure.) Depuritory: applied to fevers, which terminate in perspiration.

DERBYSHIRE SPAR. A mineral formed of calcareous earth with fluoric acid.

DE'RIS. (Δερις; from δερω, to excoriate.) The skin.

DERIVATION. (*Derivatio*; from *derivo*, to drain off.) The doctrines of derivation and revulsion, talked of by the ancients, are now, in their sense of the terms, wholly exploded. Derivation means the drawing away any disease from its original seat to another part.

DE'RMA. Δερμα. The skin. See *Skin.*

DERMATO'DES. (From δερμα, skin, and ειδος, a likeness.) Resembling skin, or leather; applied to the dura mater.

DERMATOLO'GIA. (From δερμα, the skin, and λογος, a discourse.) A discourse or treatise on the skin.

DE'RTRON. (From δερις, skin.) The omentum, and peritonæum, are so named, from their skin-like consistence.

DESAULT, PETER, was a native of Bourdeaux, where he graduated, and became distinguished as a practitioner in medicine about the beginning of the last century. He was author of some popular and useful dissertations on medical subjects. In syphilis he maintained that a cure could be effected without salivation; and in calculous complaints by the patient drinking the Bareges water, this being also injected into the bladder: but it probably merely palliated the symptoms. He exposed also some of the prevailing errors concerning hydrophobia; as that the patient barked like a dog, and had a propensity to bite his attendants. The precise period of his death is not mentioned.

DESAULT, PETER JOSEPH, was chief surgeon to the Hôtel Dieu at Paris. He published several numbers of a surgical journal in 1791, &c.; also jointly with Chopart, in 1794, "A Treatise on Chirurgical Diseases, and the Operations required in their Cure;" which is allowed to have considerable merit. He attended the young King of France, Lewis XVII., in the Temple; and died under suspicious circumstances shortly before his royal patient in 1795.

DESCENSO'RIUM. (From *descendo*, to move downwards.) A vessel in which the distillation by descent is performed.

DESCE'NSUS. (From *descendo*, to move downwards.) The same chemists call it a distillation *per descensum*, by descent, when the fire is applied at the top and round the vessel, the orifice of which is at the bottom.

DESICCATI'VE. (*Desicativus*; from *desicco*, to dry up.) An application to dry up the humours and moisture running from a wound or ulcer.

DESIPIE'NTIA. (From *desipio*, to dote.) A defect of reason.

DESIRE. Will. We give the name of will to that modification of the faculty of perception by which we form desires. It is generally the effect of our judgment; but what is remarkable, our happiness or our misery is necessarily connected with it. When we satisfy our desires we are happy; but we are miserable if our desires be not fulfilled; it is then necessary to give such a direction to our desires that we may be enabled to obtain happiness. We ought not to desire things which cannot be obtained; we ought to avoid, even with greater care, those things which are hurtful; for in such cases we must be unhappy whether our desires are satisfied or not. Morality is a science which tends to give the best possible direction to our desires.

DE'SME. (From δεω, to bind up.) A bandage, or ligature.

DESMI′DION. (From δεσμη, a handful.) A small bundle, or little bandage.

DE′SMOS. (From δεω, to bind up.) 1. A bandage.

2. An inflammatory stricture of a joint, after luxation.

DE′SPUMATION. (*Despumatio;* from *dëspumo*, to clarify.) The clarifying a fluid, or separating its foul parts from it.

DESQUAMATION. (*Desquamatio;* from *desquamo*, to scale off.) The separating of laminæ, or scales, from a bone. Exfoliation.

DESQUAMATO′RIUM. (From *desquamo*, to scale off.) A trepan, or instrument to take a piece out of the skull.

DESTILLA′TION. See *Distillation.*

DESUDA′TIO. (From *desudo*, to sweat much.) An unnatural and morbid sweating.

DETE′NTIO. (From *detineo*, to stop, or hinder.) Epilepsy is so called, from the suddenness with which the patient is seized.

DETERGENT. (From *detergo*, to wipe away.) 1. A medicine which cleanses and removes such viscid humours as adhere to and obstruct the vessels.

2. An application that clears away foulness from ulcers.

DETERMINATE. Applied by botanists to branches and stems: *determinatè ramosus* is abruptly branched, when each branch, after terminating in flowers, produces a number of fresh shoots in a circular order from just below the origin of those flowers. The term occurs frequently in the latter publication of Linnæus, particularly the second *Mantissa;* but he does not appear to have any where explained its meaning. —*Smith.*

DETONATION. (*Detonatio;* from *detono*, to make a noise.) A sudden combustion and explosion.

DETRA′CTOR. (From *detraho*, to draw.) Applied to a muscle, the office of which is to draw the part to which it is attached.

DE′TRAHENS. (From *detraho*, to draw.) The name of a muscle, the office of which is to draw the part it is attached to.

DETRAHENS QUADRATUS. See *Platysma myoides.*

DETRU′SOR URINÆ. (From *detrudo*, to thrust out.) 1. The name of a muscle, the office of which is to squeeze out the urine.

2. The muscular coat of the urinary bladder was formerly so called.

DEU′TERI. (From δευτερος, second; because it is discharged next after the fœtus.) The secundines, or after-birth.

DEUTEROPA′THIA. (From δευτερος, second, and ϖαθος, a suffering.) An affection or suffering by consent, where a second part suffers, from consent, with the part originally affected, as where the stomach is disturbed through a wound in the head.

DEUTOXIDE. See *Oxide.*

Deutoxide of azot. See *Nitrogen.*

DEVENTER, HENRY, was born in Holland, towards the end of the 17th century. He took a degree in medicine, but his practice was principally in surgery, and at last almost confined to midwifery. He distinguished himself much by his improvements in this art, as well as by his mechanical inventions for obviating deformities in children. He published some obstetrical works several years prior to his death, which occurred in 1739; after which appeared a Treatise on the Rickets in his native language, of which Haller makes favourable mention.

Devil's dung. See *Ferula assafœtida.*

DIA. Δια. Many terms in medicine, surgery, and pharmacy commence with this word, when they signify composition and mixture; as *Diacassia*, *Diacastoreum*, &c.

DIABE′CUS. (From διαβεβαιοω, to strengthen; so called, as affording the chief support to the foot.) The ankle-bone.

DIABE′TES. (From δια, through, and βαινω, to pass.) An immoderate flow of urine. A genus of disease in the class *Neuroses*, and order *Spasmi* of Cullen.

There are two species in this complaint:

1. *Diabetes insipidus*, in which there is a superabundant discharge of limpid urine, of its usual urinary taste.

2. *Diabetes mellitus*, in which the urine is very sweet, and contains a great quantity of sugar.

Great thirst, with a voracious appetite, gradual emaciation of the whole body, and a frequent discharge of urine, containing a large proportion of saccharine and other matter, which is voided in a quantity even exceeding that of the aliment or fluid introduced, are the characteristics of this disease. Those of a shattered constitution, and those who are in the decline of life, are most subject to its attacks. It not unfrequently attends on hysteria, hypochendriasis, dyspepsia, and asthma; but it is always much milder when symptomatic, than when it appears as a primary affection.

Diabetes may be occasioned by the use of strong diuretic medicines, intemperance of life, and hard drinking; excess in venery, severe evacuations, or by any thing that tends to produce an impoverished state of the blood, or general debility. It has, however, taken place, in many instances, without any obvious cause.

That which immediately gives rise to the disease, has ever been considered as obscure, and various theories have been advanced on the occasion. It has been usual to consider diabetes as the effect of relaxation of the kidneys or as depending on a general colliquation of the fluids. Dr. Richter, professor of medicine in the university of Gottingen, supposes the disease to be generally of a spasmodic nature, occasioned by a stimulus acting on the kidneys; hence a *secretio aucta urinæ*, and sometimes *perversa*, is the consequence. Dr. Darwin thinks that it is owing to an *inverted* action of the urinary branch of the lymphatics; which doctrine, although it did not escape the censure of the best anatomists and experienced physiologists, met, nevertheless, with a very favourable reception on its being first announced. The late Dr. Cullen offered it as his opinion, that the proximate cause of this disease might be some fault in the assimilatory powers, or in those employed in converting alimentary matters into the proper animal fluids, which theory has since been adopted by Dr. Dobson, and still later by Dr. Rollo, surgeon-general to the royal artillery. The liver has been thought, by some, to be the chief source of the disease; but diabetes is hardly ever attended with any affection of this organ, as has been proved by frequent dissections; and when observed, it is to be considered as accidental.

The primary seat of the disease is, however, far from being absolutely determined in favour of any hypothesis yet advanced; and, from the most attentive consideration of all the circumstances, the weight of evidence appears to induce the majority of practitioners to consider diabetes as depending on a primary affection of the kidneys.

Diabetes sometimes comes on slowly and imperceptibly, without any previous disorder; and it now and then arises to a considerable degree, and subsists long without being accompanied with evident disorder in any particular part of the system; the great thirst which always, and the voracious appetite which frequently occur in it, being often the only remarkable symptoms; but it more generally happens, that a considerable affection of the stomach precedes the coming on of the disease; and that, in its progress, besides the symptoms already mentioned, there is a great dryness in the skin, with a sense of weight in the kidneys, and a pain in the ureters, and the other urinary passages.

Under a long continuance of the disease, the body becomes much emaciated, the feet œdematous, great debility arises, the pulse is frequent and small, and an obscure fever, with all the appearance of hectic, prevails.

The urine in diabetes mellitus, from being at first insipid, clear, and colourless, soon acquires a sweetish or saccharine taste, its leading characteristic; and, when subjected to experiment, a considerable quantity of saccharine matter is to be extracted from it. Sometimes it is so loaded with sugar, as to be capable of being fermented into a vinous liquor. Upwards of one-twelfth of its weight of sugar was extracted from some diabetic urine, by Cruickshank, which was at the rate of twenty-nine ounces troy a day, from one patient.

In some instances, the quantity of urine in diabetes is much greater than can be accounted for from all the sources united. Cases are recorded, in which 25 to 30 pints were discharged in the space of a natural day, for many successive weeks, and even months; and in which the whole ingesta, as was said, did not amount to half the weight of the urine. To account for this overplus, it has been alleged that water is absorbed from the air by the surface of the body; as also that a quantity of water is compounded in the lungs themselves.

Dissections of diabetes have usually shown the kidneys to be much affected. In some instances, they have been found in a loose flabby state, much enlarged in size, and of a pale ash colour; in others, they have been discovered much more vascular than in a healthy state, approaching a good deal to what takes place in inflammation, and containing, in their infundibula, a quantity of whitish fluid, somewhat resembling pus, but without any sign of ulceration whatever. At the same time that these appearances have been observed in their interior, the veins on their surface were found to be much fuller of blood than usual, forming a most beautiful net-work of vessels, the larger branches of which exhibited an absorbent appearance. In many cases of dissection, the whole of the mesentery has been discovered to be much diseased, and its glands remarkably enlarged; some of them being very hard, and of an irregular texture; others softer, and of an uniform spherical shape. Many of the lacteals have likewise been seen considerably enlarged. The liver, pancreas, spleen, and stomach, are in general perceived to be in a natural state; when they are not so, the occurrence is to be considered as accidental. The bladder, in many cases, is found to contain a considerable quantity of muddy urine.

A great variety of remedies has been proposed for this disease; but their success is generally precarious, or only temporary, at least in the mellitic form of the complaint. The treatment has been generally conducted on the principles of determining the fluids to other outlets, particularly the skin, and of increasing the tone of the kidneys. Diaphoretics are certainly very proper remedies, especially the combination of opium with ipecacuanha, or antimonials, assisted by the warm bath, suitable clothing, and perhaps removal to a milder climate: in the insipid form of diabetes, this plan has sometimes effected a cure; and it appears that the large use of opium has even the power of correcting, for the time, the saccharine quality of the urine. Cathartics are hardly of service, farther than to keep the bowels regular. Tonics are generally indicated by obvious marks of debility; and if the patient be troubled with acidity in the primæ viæ, alkaline medicines will be properly joined with them, preferring those which have no diuretic power. Astringents have been highly extolled by some practitioners, but do not appear likely to avail, except those which pass off by the urine, as uva ursi; or the milder stimulants, which can be directed to the kidneys, as copaiba, &c. may correct the laxity of those organs, if the disease depend on this cause. The tinctura lyttæ must be used with great caution, and its efficacy is not well established: and blisters to the loins can only be useful as counter-irritants, though not the most suitable. Frequent friction, especially over the kidneys, wearing a tight belt, and gentle exercise, may assist the recovery of the patient; and when the function of the skin is restored, using the bath gradually of a lower temperature, will tend greatly to obviate its suppression afterwards. It is likewise highly important to regulate the diet, especially in the mellitic diabetes. Dr. Rollo first pointed out the advantage derived from restricting the patient to a diet principally of animal food, avoiding especially those vegetables which might afford saccharine matter, the urine becoming thereby of a more healthy quality, and diminishing in quantity: but unfortunately the benefit appears but temporary, and the plan is not persevered in without distress to the patient. The same gentleman recommended also the sulphuret of potassa, and still more the hydrosulphuret of ammonia; but they are very nauseous medicines, and of doubtful efficacy. Another plan of treating the disease has been more recently proposed, namely, by bleeding, and other antiphlogistic measures; and some cases of its success have been recorded; but farther experience is certainly required, before we should be justified in relying much upon it.

Dia′bolus metallorum. Tin.

Diabo′tanum. (From *δια* and *βοτανη*, an herb.) A plaster made of herbs.

Diaca′dmias. (From *δια*, and *καδμια*, cadmia.) The name of a plaster, the basis of which is cadmia.

Diacalami′nthes. (From *δια*, and *καλαμινθη*, calamint.) The name of an antidote, the chief ingredient in which is calamint.

Diaca′rcinum. (From *δια*, and *καρκινος*, a crab.) The name of an antidote prepared from the flesh of crabs and cray-fish.

Diaca′ryon. (From *δια*, and *καρυον*, a nut.) Rob of nuts, or walnuts.

Diaca′ssia. (From *δια*, and *κασσια*, cassia.) Electuary of cassia.

Diacasto′rium. (From *δια*, and *καςωρ*, castor.) An antidote, the basis of which is castor.

Diacatho′licon. (From *δια*, and *καθολικος*, universal.) The name of a purge, so called from its general usefulnesss.

Diacentau′rium. (From *δια*, and *κενταυριον*, centaury.) The Duke of Portland's powder is so called, because its chief ingredient is centaury.

Diacentro′tum. (From *δια*, and *κεντροω*, to prick.) A collyrium, so called from its pungency and stimulating qualities.

Diachalci′tis. (From *δια*, and *χαλκιτις*, chalcitis.) A plaster, the chief ingredient in which is chalcitis.

DIACHA′LSIS. (From διαχαλω, to be relaxed.) 1. A relaxation.

2. The opening of the sutures of the head.

DIACHEIRI′SMUS. (From δια, and χειρ, the hand.) Any operation performed by the hand.

DIACHELIDO′NIUM. (From δια, and χελιδωνιον, celandine.) A plaster, the chief ingredient in which was the herb celandine.

DIACHORE′MA. (From διαχωρεω, to separate from.) *Diachoresis.* Any excretion, or excrement, but chiefly that by stool.

DIACHORE′SIS. See *Diachorema.*

DIACHARI′STA. (From δια, and χριω, to anoint.) Medicines to anoint parts.

DIACHRY′SUM. (From δια, and χρυσος, gold.) A plaster for fractured limbs; so named from its yellow colour.

DIA′CHYLUM. (From δια, and χυλος, juice.) A plaster formerly made of certain juices, but it now means an emollient digestive plaster.

DIA′CHYSIS. (From δια, and χυω, to pour out.) Fusion or melting.

DIACHY′TICA. (From διαχυω, to dissolve.) Medicines which discuss tumours.

DIACINE′MA. (From δια, and κινεω, to move.) A slight dislocation.

DIACI′SSUM. (From δια, and κισσος, ivy.) An application composed of ivy leaves.

DIA′CLASIS. (From δια, and χλαω, to break.) A small fracture.

DIACLY′SMA. (From διακλυζω, to wash out.) A gargle or wash for the mouth.

DIACOCCYME′LON. (From δια, and κοκκυμηλον, a plum.) An electuary made of prunes.

DIACO′DIUM. (From δια, and κωδια, a poppy head.) A composition made of the heads of poppies.

DIACOLOCY′NTHIS. (From δια, and κολοκυνθις, the colocynth.) A preparation, the chief ingredient of which is colocynth.

DIACO′MMA. (From διακοπτω, to cut through.) *Diacope.* A deep cut or wound.

DIA′COPE. See *Diacomma.*

DIACOPRÆ′GIA. (From δια, κοπρος, dung, and αιξ, a goat.) A preparation with goat's dung.

DIACORA′LLUM. (From δια, and κοραλλιον, coral.) A preparation in which coral is a chief ingredient.

DIA′CRISIS. (From διακρινω, to distinguish.) The distinguishing diseases one from another by their symptoms.

DIACRO′CIUM. (From δια, and κροκος, saffron.) A collyrium in which is saffron.

DIACURCU′MA. (From δια, and κυρκουμα, turmeric.) An antidote in which is turmeric or saffron.

DIACYDO′NIUM. (From δια, and κυδωνια, a quince.) Marmalade of quinces.

DIADAPHNI′DION. (From δια, and δαφνις, the laurel tree.) A drawing plaster in which were bay-berries.

DIADE′LPHIA. (From δις, twice, and αδελφις, a brotherhood; two brotherhoods.) The name of a class in the sexual system of plants, embracing those the flowers of which are hermaphrodites, and have the male organs united below into two sets of cylindrical filaments.

DIADE′MA. (From διαδεω, to surround.) 1. A diadem or crown.

2. A bandage to put round the head.

DIADE′XIS. (From διαδεχομαι, to transfer.) *Diadoche.* A transposition of humours from one place to another.

DIA′DOCHE. See *Diadexis.*

DIA′DOSIS. (From διαδιδωμι, to distribute.) The remission of a disorder.

DIÆ′RESIS. (From διαιρεω, to divide or separate.) A solution of continuity of the soft parts of the human body.

DIÆRE′TICA. (From διαιρεω, to divide.) Corrosive medicines.

DIÆ′TA. (From διαιταω, to nourish.) Diet; food. It means also the whole of the non-naturals. See *Diet.*

DIAGLAU′CIUM. (From δια, and γλαυκιον, the blue juice of an herb.) An eye-water made of the purging thistle.

DIAGNO′SIS. (From διαγινωσκω, to discern or distinguish.) The science which delivers the signs by which a disease may be distinguished from another disease: hence those symptoms which distinguish such affections are termed *diagnostic.*

DIAGRY′DIUM. Corrupted from dacrydium or scammony.

DIAHERMODA′CTYLUM. (From δια, and ερμοδακτυλος, the hermodactyl.) A purging medicine, the basis of which is the hermodactyl.

DIAI′REON. (From δια, and ιρις, the lily.) An antidote in which is the root of the lily.

DIAI′UM. (From δια, and ιον, a violet.) A pastil, the chief ingredient of which is violets.

DIALA′CCA. (From δια, and λακκα.) An antidote in which is the lacca.

DIALAGO′UM. (From δια, and γαλως, a hare.) A medicine in which is the dung of a hare.

DIALE′MMA. (From διαλαμβανω, to interrupt.) The remission of a disease.

DIALE′PSIS. (From διαλαμβανω, to interrupt.) 1. An intermission.

2. A space left between a bandage.

DIALI′BANUM. (From δια, and λιβανον, frankincense.) A medicine in which frankincense is a chief ingredient.

DIALLAGE. Smaragdite of Saussure. *Verde di Corsica duro* of artists. A species of the genus Schiller spar. It is a mineral of a greenish colour, composed of silica, alumina, magnesia, lime, oxide of iron, oxide of copper, and oxide of chrome. It is found principally in Corsica.

DIA′LOES. (From δια, and αλοη, the aloe.) A medicine chiefly composed of aloes.

DIALTHÆ′A. (From δια, and αλθαια, the mallow.) An ointment composed chiefly of marshmallows.

DIA′LYSIS. (From διαλυω, to dissolve.) A solution of continuity, or a destruction of parts.

DIA′LYSES. The plural of dialysis. The name of an order in the class *Locales* of Cullen's Nosology.

DIALY′TICA. (From διαλυω, to dissolve.) Medicines which heal wounds and fractures.

DIAMARGARI′TON. (From δια, and μαργαριτις, pearl.) An antidote in which pearls are the chief ingredient.

DIAMASSE′MA. (From δια, and μασσομαι, to chew.) A masticatory, or substance put into the mouth, and chewed to excite a discharge of the saliva.

DIA′MBRA. (From δια, and αμβρα, amber.) An aromatic composition in which was ambergris.

DIAME′LON. (From δια, and μηλον, a quince.) A composition of quinces.

DIAMI′SYOS. (From δια, and μισυ, misy.) A composition in which misy is an ingredient.

DIAMOND. The diamond, which was well known to the ancients, is principally found in the western peninsula of India, on the coast of Coromandel, in the kingdoms of Colconda and Visapour, in the island of Borneo, and in the Brazils. It is the most valued of all minerals.

Diamonds are generally found bedded in yellow ochre or in rocks of free-stone, or quartz, and sometimes in the beds of running waters. When taken out of the earth they are incrusted with an exterior earthy covering, under which is another, consisting of carbonate of lime.

In the Brazils, it is supposed that diamonds might be obtained in greater quantities than at present, if the sufficient working of the diamond-mines was not prohibited, in order to prevent that diminution of their commercial value, which a greater abundance of them might occasion.

Brazilian diamonds are, in commercial estimation, inferior to the oriental ones.

In the rough, diamonds are worth two pounds sterling the carat, or four grains, provided they are without blemish. The expense of cutting and polishing amounts to about four pounds more. The value however is far above what is now stated when they become considerable in size. The greatest sum that has been given for a single diamond is one hundred and fifty thousand pounds.

The usual method of calculating the value of diamonds is by squaring the number of carats, and then multiplying the amount by the price of a single carat: thus supposing one carat to be *2l.* a diamond of 8 carats is worth *128l.* being 8 × 8 × 2.

The famous Pigot diamond weighs 188 1-8th grains.

Physical Properties of Diamond.

Diamond is always crystallised, but sometimes so imperfectly, that, at first sight, it might appear amorphous. The figure of diamond, when perfect, is an eight-sided prism. There are also cubical, flat, and round diamonds. It is the oriental diamond which crystallises into octohedra, and exhibits all the varieties of this primitive figure. The diamond of Brazil crystallises into dodecahedra.

The texture of the diamond is lamellated, for it may be split or cleft with an instrument of well-tempered steel, by a swift blow in a particular direction. There are however some diamonds which do not appear to be formed of *laminæ*, but of twisted and interwoven fibres, like those of knots in wood. These exceed the others greatly in hardness, they cannot be cut or polished, and are therefore called by the lapidaries *diamonds of nature.*

The diamond is one of the hardest bodies known. It resists the most highly-tempered steel file, which circumstance renders it necessary to attack it with diamond powder. It takes an exquisite and lasting polish. It has a great refractive power, and hence its lustre, when cut into the form of a regular solid, is uncommonly great. The usual colour of diamonds is a light grey, often inclining to yellow, at times lemon colour, violet, or black, seldomer rose-red, and still more rarely green or blue, but more frequently pale brown. The purest diamonds are perfectly transparent. The colourless diamond has a specific gravity which is in proportion to that of water, as 3.512 to 1.000, according to Brisson. This varies however considerably. When rubbed it becomes *positively* electric, even before it has been cut by the lapidary.

Diamond is not acted upon by acids, or by any chemical agent, oxygen excepted; and this requires a very great increase of temperature to produce any effect.

The diamond burns by a strong heat, with a sensible flame, like other combustible bodies, attracting oxygen, and becoming wholly converted into carbonic acid gas during that process.

It combines with iron by fusion, and converts it, like common charcoal, into steel; but diamond requires a much higher temperature for its combustion than common charcoal does, and even then it consumes but slowly, and ceases to burn the instant its temperature is lowered.

"From the high refractive power of the diamond, Biot and Arago supposed that it might contain hydrogen. Sir H. Davy, from the action of potassium on it, and its non-conduction of electricity, suggested in his third Bakerian lecture, that a minute portion of oxygen might exist in it; and in his new experiments on the fluoric compounds, he threw out the idea, that it might be the carbonaceous principle, combined with some new, light, and subtle element of the oxygenous and chlorine class.

This unrivalled chemist, during his residence at Florence in March 1814, made several experiments on the combustion of the diamond and of plumbago, by means of the great lens in the cabinet of natural history; the same instrument as that employed in the first trials on the action of the solar heat on the diamond, instituted in 1694 by Cosmo III. Grand Duke of Tuscany. He subsequently made a series of researches on the combustion of different kinds of charcoal at Rome. His mode of investigation was peculiarly elegant, and led to the most decisive results.

He found that diamond, when strongly ignited by the lens, in a thin capsule of platinum, perforated with many orifices, so as to admit a free circulation of air, continued to burn with a steady brilliant red light, visible in the brightest sunshine, after it was withdrawn from the focus. Some time after the diamonds were removed out of the focus, indeed, a wire of platina that attached them to the tray was fused, though their weight was only 1.84 grains. His apparatus consisted of clear glass globes of the capacity of from 14 to 40 cubic inches, having single apertures to which stop-cocks were attached. A small hollow cylinder of platinum was attached to one end of the stop-cock, and was mounted with the little perforated capsule for containing the diamond. When the experiment was to be made, the globe containing the capsule and the substance to be burned was exhausted by an excellent air-pump, and pure oxygen, from chlorate of potassa, was then introduced. The change of volume in the gas after combustion was estimated by means of a fine tube connected with a stop-cock, adapted by a proper screw to the stop-cock of the globe, and the absorption was judged of by the quantity of mercury that entered the tube which afforded a measure so exact, that no alteration however minute could be overlooked. He had previously satisfied himself that a quantity of moisture, less than 1-100th of a grain, is rendered evident by deposition on a polished surface of glass; for a piece of paper weighing one grain was introduced into a tube of about four cubic inches' capacity, whose exterior was slightly heated by a candle. A dew was immediately perceptible on the inside of the glass, though the paper, when weighed in a balance turning with 1-100th of a grain, indicated no appreciable diminution.

The diamonds were always heated to redness before they were introduced into the capsule. During their combustion; the glass globe was kept cool by the application of water to that part of it immediately above the capsule, and where the heat was greatest.

From the results of his different experiments, conducted with the most unexceptionable precision, it is demonstrated, that diamond affords no other substance by its combustion than pure carbonic acid gas; and that the process is merely a solution of diamond in oxygen, without any change in the volume of the gas. It likewise appears, that in the combustion of the different kinds of charcoal, water is produced; and that from the diminution of the volume of the oxygen, there is every reason to believe that the water is formed by the combustion of hydrogen existing in strongly ignited charcoal. As the charcoal from oil of turpentine left no residuum, no other cause but the presence of hydrogen can be assigned for the diminution occasioned in the volume of the gas during its combustion.

The only chemical difference perceptible between diamond and the purest charcoal is, that the last contains a minute portion of hydrogen; but can a quantity of an element, less in some cases than 1-50,000th part of the weight of the substance, occasion so great a difference in physical and chemical characters? The opinion of Tennant, that the difference depends on crystallisation, seems to be correct. Transparent solid bodies are in general non-conductors of electricity; and it is probable that the same corpuscular arrangements which give to matter the power of transmitting and polarising light, are likewise connected with its relations to electricity. Thus water, the hydrates of the alkalies, and a number of other bodies which are conductors of electricity when fluid, become non-conductors in their crystallised form.

That charcoal is more inflammable than the diamond, may be explained from the looseness of its texture, and from the hydrogen it contains. But the diamond appears to burn in oxygen with as much facility as plumbago, so that at least one distinction supposed to exist between the diamond and common carbonaceous substances is done away by these researches. The power possessed by certain carbonaceous substances of absorbing gases, and separating colouring matters from fluids, is probably mechanical and dependent on their porous organic structure; for it belongs in the highest degree to vegetable and animal charcoal, and it does not exist in plumbago, coak, or anthracite.

The nature of the chemical difference between the diamond and other carbonaceous substances, may be demonstrated by igniting them in chlorine, when muriatic acid is produced from the latter, but not from the former. The visible acid vapour is owing to the moisture present in the chlorine uniting to the dry muriatic gas. But charcoal, after being intensely ignited in chlorine, is not altered in its conducting power of colour. This circumstance is in favour of the opinion, that the minute quantity of hydrogen is not the cause of the great difference between the physical properties of the diamond and charcoal." See *Carbon*.

Diamond-shaped. See *Leaf*.

DIAMO′RON. (From *δια*, and *μωρον*, a mulberry.) A preparation of mulberries.

DIAMO′SCHUM. (From *δια*, and *μοσχος*, musk.) An antidote in which musk is a chief ingredient.

DIAMOTO′SIS. (From *δια*, and *μοτος*, lint.) The introduction of lint into an ulcer or wound.

DIA′NA. 1. the moon.

2. The chemical name for silver from its white shining appearance.

DIANANCA′SMUS. (From *δια*, and *αναγκαζω*, to force.) 1. the forcible restoration of a luxated part into its proper place.

2. An instrument to reduce a distorted spine.

DIA′NDRIA. (From *δις* twice, and *ανηρ*, a man.) The name of a class in the sexual system, consisting of hermaphrodite plants which have flowers with two staminæ.

DIA′NTHUS. (From *Δις*, *διος*, Jove, and *ανθος*, a flower: so called from the elegance and fragrance of its flower.) The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order, *Digynia*.

DIANTHUS CARYOPHYLLUS. The systematic name of the clove-pink. *Caryophyllum rubrum*; *Tunica*; *Vetonica*; *Betonica*; *Coronaria*; *Caryophyllus hortensis*. Clove gilliflower. Clove July flower. This fragrant plant, *Dianthus—floribus solitariis, squamis calycinis subovatis, brevissimis, corollis crenatis*, of Linnæus, grows wild in several parts of England; but the flowers, which are pharmaceutically employed, are usually produced in gardens: they have a pleasant aromatic smell, somewhat allied to that of clove-spice; their taste is bitterish and sub-adstringent. These flowers were formerly in extensive use, but are now merely employed in form of syrup, as a useful and pleasant vehicle for other medicines.

DIAPA′SMA. (From *διαπασσω*, to sprinkle.) A medicine reduced to powder and sprinkled over the body, or any part.

DIAPEDE′SIS. (From *διαπηδαω*, to leap through.) The transudation or escape of blood through the coats of an artery.

DIAPE′GMA. (From *διαπηγνυω*, to close together.) A surgical instrument for closing together broken bones.

DIAPE′NTE. (From *δια*, and *πεντε*, five.) A medicine composed of five ingredients.

DIAPHANOUS. (*Diaphanosus*; from *δια* through, and *φαινω*, to shine.) A term applied to any substance which is transparent; as the hyaloid membrane covering the vitreous humour of the eye, which is as transparent as glass.

DIAPHŒ′NICUM. (From *δια*, and *φοινιξ*, a date.) A medicine made of dates.

DIA′PHORA. (From *διαφερω*, to distinguish.) The distinction of diseases by their characteristic marks and symptoms.

DIAPHORE′SIS. (From *διαφορεω*, to carry through.) Perspiration.

DIAPHORETIC. (*Diaphoreticus*; from *διαφορεω*, to carry through.) That which, from being taken internally, increases the discharge by the skin. When this is carried so far as to be condensed on the surface, it forms sweat: and the medicine producing it is named sudorific. Between diaphoretic and sudorific there is no distinction; the operation is in both cases the same, and differs only in degree from augmentation of dose, or employment of assistant means. This class of medicines comprehends five orders.

1. *Pungent Diaphoretics*, as the *volatile salts*, and *essential oils*, which are well adapted for the aged; those in whose system there is little sensibility; those who are difficultly affected by other diaphoretics; and those whose stomachs will not bear large doses of medicines.

2. *Calefacient diaphoretics*, such as *serpentaria contrayerva*, and *guaiacum*: these are given in cases where the circulation is low and languid.

3. *Stimulant diaphoretics*, as antimonial and mercurial preparations, which are best fitted for the vigorous and plethoric.

4. *Antispasmodic diaphoretics*, as *opium*, *musk*, and *camphire*, which are given to produce a diaphoresis, when the momentum of the blood is increased.

5. *Diluent diaphoretics*, as water, whey, &c. which are best calculated for that habit in which a predisposition to sweating is wanted, and in

which no diaphoresis takes place, although there be evident causes to produce it.

DIAPHRA'GMA. (*Diaphragma, matis.* n.; from δια, and φραττω, to divide.) *Septum transversum.* The midrif, or diaphragm. A muscle that divides the thorax from the abdomen. It is composed of two muscles; the first and superior of these arises from the sternum, and the ends of the last ribs on each side. Its fibres, from this semicircular origination, tend towards their centre, and terminate in a tendon, or aponeurosis, which is termed the *centrum tendinosum.* The second and inferior muscle comes from the vertebræ of the loins by two productions, of which that on the right side comes from the first, second, and third vertebræ of the loins; that on the left side is somewhat shorter, and both these portions join and make the lower part of the diaphragm, which joins its tendons with the tendon of the other, so that they make but one muscular partition. It is covered by the pleura on its upper side, and by the peritonæum on the lower side. It is pierced in the middle for the passage of the vena cava; in its lower part for the œsophagus, and the nerves, which go to the upper orifice of the stomach, and betwixt the productions of the inferior muscle, passes the aorta, the thoracic duct, and the vena azygos. It receives arteries and veins called phrenic or diaphragmatic, from the cava and aorta: and sometimes on its lower part two branches from the vena adiposa, and two arteries from the lumbares. It has two nerves which come from the third vertebra of the neck, which pass through the cavity of the thorax, and are lost in its substance. In its natural situation, the diaphragm is convex on the upper side towards the breast, and concave on its lower side towards the belly; therefore, when its fibres swell and contract, it must become plain on each side, and consequently the cavity of the breast is enlarged to give liberty to the lungs to receive air in inspiration; and the stomach and intestines are pressed for the distribution of their contents; hence the use of this muscle is very considerable; it is the principal agent in respiration, particularly in inspiration; for when it is in action the cavity of the thorax is enlarged, particularly at the sides, where the lungs are chiefly situated: and as the lungs must always be contiguous to the inside of the thorax and upper side of the diaphragm, the air rushes into them, in order to fill up the increased space. In expiration it is relaxed and pushed up by the pressure of the abdominal muscles upon the viscera of the abdomen; and at the same time that they press it upwards, they pull down the ribs, by which the cavity of the thorax is diminished, and the air suddenly pushed out of the lungs.

DIAPHRAGMATI'TIS. (From διαφραγμα, the diaphragm.) Inflammation of the diaphragm. See *Paraphrenitis.*

DIA'PHTHORA. (From διαφθειρω, to corrupt.) An abortion where the fœtus is corrupted in the womb.

DIAPHYLA'CTICA. (From διαφυλασσω, to preserve.) Medicines which resist putrefaction or prevent infection.

DIA'PHYSIS. (From διαφυω, to divide.) An interstice or partition between the joints.

DIAPISSELÆ'UM. (From δια, and πισσελαιον, the oil of pitch, or liquid pitch.) A composition in which is liquid pitch,

DIA'PLASIS. (From διαπλασσω, to put together.) The replacing a luxated or fractured bone in its proper situation.

DIAPLA'SMA. (From διαπλασσω, to anoint.) An unction or fomentation applied to the whole body or any part.

DIA'PNE. (From διαπνεω, to blow through, or pass gently as the breath does.) An insensible discharge of the urine.

DIA'PNOE. (From διαπνεω, to breathe through.) The transpiration of vapour through the pores of the skin.

DIAPNO'ICA. (From διαπνεω, to transpire.) Diaphoretics or medicines which promote perspiration.

DIAPORE'MA. (From διαπορεω, to be in doubt.) Nervous anxiety.

DIAPORON. (From δια, and οπωρα, autumnal fruits.) A composition in which are several autumnal fruits, as quinces, medlars, and services.

DIAPRA'SSIUM. (From δια, and πρασσιον, horehound.) A composition in which horehound is the principal ingredient.

DIAPRU'NUM. (From δια, and προυνη, a prune.) An electuary of prunes.

DIAPSO'RICUM. (From δια, and ψωρα, the itch or scurvy.) A medicine for the itch or scurvy.

DIAPTE'RNES. (From δια, and πτερνα, the heel.) A composition of cow heel and cheese.

DIAPTERO'SIS. (From δια, and πτερον, a feather.) The cleaning the ears with a feather.

DIAPYE'MA. (From δια, and πυον, pus.) A suppuration or abscess.

DIAPYE'MATA. (From διαπυημα, a suppuration.) Suppurating medicines.

DIAPYE'TICA. (From διαπυημα, a suppuration.) Suppurating applications.

DIARHO'CHA. (From δια, and ρηχος, a space.) The space between the foldings of a bandage.

DIA'RIUS. (From *dies*, a day.) A term applied to fevers which last but one day.

DIAROMA'TICUM. (From δια, and αρωματικον, an aromatic.) A composition of spices.

DIA'RRHAGE. (From διαρρηγνυμι, to break asunder.) A fracture.

DIARRHODO'MELI. (From δια, ροδον, a rose, and μελι, honey.) Scammony, agaric, pepper and honey.

DIA'RRHODON. (From δια, and ροδον, a rose.) A composition of roses.

DIARRHŒ'A. (From διαρρεω, to flow through. A purging. It is distinguished by frequent stools with the natural excrement, not contagious, and seldom attended with pyrexia. It is a genus of disease in the class *Neuroses*, and order *Spasmi* of Cullen, containing the following species:

1. *Diarrhœa crapulosa.* The feculent diarrhœa, from *crapulus*, one who overloads his stomach.

2. *Diarrhœa biliosa.* The bilious, from an increased secretion of bile.

3. *Diarrhœa mucosa.* The mucous, from a quantity of slime being voided.

4. *Diarrhœa hepatirrhœa.* The hepatic, in which there is a quantity of serous matter, somewhat resembling the washings of flesh, voided; the liver being primarily affected.

5. *Diarrhœa lienterica.* The lientery; when the food passes unchanged.

6. *Diarrhœa cœliaca.* The cœliac passion: the food passes off in this affection in a white liquid state like chyle.

7. *Diarrhœa verminosa.* Arising from worms.

Diarrhœa seems evidently to depend on an increase of the peristaltic motion, or of the secretion of the intestines; and besides the causes already noticed, it may arise from many others, influencing the system generally, or the particular seat of the disease. Of the former kind are cold, checking perspiration, certain passions of the mind, and other disorders; as dentition, gout, fever, &c. To the latter belong various acrid ingesta, drastic cathartics, spontaneous acidity, &c. In this complaint each discharge is usually preceded by a murmuring noise, with a sense of weight and uneasiness in the hypogastrium. When it is protracted, the stomach usually becomes affected with sickness, or sometimes vomiting, the countenance grows pale or sallow, and the skin generally dry and rigid. Ultimately great debility and emaciation, with dropsy of the lower extremities, often supervene. Dissections of diarrhœa, where it terminated fatally, have shown ulcerations of the internal surface of the intestines, sometimes to a considerable extent, especially about the follicular glands; in which occasionally a cancerous character has been observable. The treatment of this complaint must vary greatly according to circumstances: sometimes we can only hope to palliate, as when it occurs in the advanced period of phthisis pulmonalis; sometimes it is rather to be encouraged, relieving more serious symptoms, as a bilious diarrhœa coming on in fever, though still some limits must be put to the discharge. Where, however, we are warranted in using the most speedy means of stopping it, the objects are, 1. To obviate the several causes. 2. To lessen the inordinate action, and give tone to the intestine.

I. Emetics may sometimes be useful, clearing out the stomach, and liver, as well as determining to the skin. Cathartics also expelling worms, or indurated fæces; but any acrimony in the intestine would probably cause its own discharge, and where there is much irritability, they might aggravate the disease: however, in protracted cases, the alvine contents speedily become vitiated, and renew the irritation; which may be best obviated by an occasional mild aperient, particularly rhubarb. If, however, the liver do not perform its office, the intestine will hardly recover its healthy condition: and that may most probably be effected by the cautious use of mercury. Likewise articles which determine the fluids to other outlets, diuretics, and particularly diaphoretics, in many cases contribute materially to recovery; the latter perhaps assisted by bathing, warm clothing, gentle exercise, &c. Diluent, demulcent, antacid, and other chemical remedies, may be employed to correct acrimony, according to its particular nature. In children teething, the gums should be lanced; and if the bowels have been attacked on the repulsion of some other disease, it may often be proper to endeavour to restore this. But a matter of the greatest importance is the due regulation of the diet, carefully avoiding those articles, which are likely to disagree, or irritate the bowels, and preferring such as have a mild astringent effect. Fish, milk, and vegetables, little acescent, as rice, bread, &c. are best; and for the drink, madeira or brandy, sufficiently diluted rather than malt liquors.

II. Some of the means already noticed will help to fulfil the second indication also, as a wholesome diet, exercise, diaphoretics, &c.: but there are others of more power, which must be resorted to in urgent cases. At the head of these is opium, a full dose of which frequently at once effects a cure; but where there is some more fixed cause, and the complaint of any standing, moderate quantities repeated at proper intervals will answer better, and other subsidiary means ought not to be neglected; aromatics may prevent its disordering the stomach, rhubarb obviate its causing permanent constipation, &c. Tonics are generally proper, the discharge itself inducing debility, and where there is a deficiency of bile particularly, the lighter forms of the aromatic bitters, as the infusum calumbæ, &c. will materially assist; and mild chalybeates are sometimes serviceable. In protracted cases astringents come in aid of the general plan, and where opium disagrees, they may be more necessary: but the milder ones should be employed at first, the more powerful only where the patient appears sinking. Chalk and lime-water answer best where there is acidity; otherwise the pomegranate rind, logwood extract, catechu, kino, tormentil, &c. may be given: where these fail, alum, sulphate of zinc, galls, or superacetate of lead.

DIARTHRO'SIS. (From διαρθροω, to articulate.) A moveable connection of bones. This genus has five species, viz. enarthrosis, arthrodia, ginglymus, trochoides, and amphiarthrosis.

DIASAPO'NIUM. (From δια, and σαπων, soap.) An ointment of soap.

DIASATY'RIUM. (From δια, and σατυριον, the orchis.) An ointment of the orchis-root.

DIASCI'LLIUM. (From δια, and σκιλλα, the squill.) Oxymel and vinegar of squills.

DIASCI'NCUS. (From δια, and σκιγκος, the crocodile.) A name for the mithridate, in the composition of which there was a part of the crocodile.

DIASCO'RDIUM. (From δια, and σκορδιον, the water germander.) Electuary of scordium.

DIASE'NA. (From δια, and *sena*.) A medicine in which is senna.

DIASMY'RNUM. (From δια, and σμυρνη, myrrh.) *Diasmyrnes*. A wash for the eyes composed of myrrh.

DIASO'STICUS. (From διασωζω, to preserve.) That which preserves health.

DIASPE'RMATUM. (From δια, and σπερμα, seed.) A medicine composed chiefly of seeds.

DIA'SPHAGE. (From διασφαζω, to separate.) *Diasphaxis*. The interstice between two veins.

DIASPHY'XIS. (From δια, and σφυζω, to strike.) The pulsation of an artery.

DIA'STASIS. (From διιστημι, to separate.) *Diastema*. A separation. A separation of the ends of bones; as that which occasionally happens to the bones of the cranium, in some cases of hydrocephalus.

DIASTE'ATON. (From δια, and ςεαρ, fat.) An ointment of the fat of animals.

DIASTE'MA. See *Diastasis*.

DIASTOLE. (From δια, and στελλω, to stretch.) The dilatation of the heart and arteries. See *Circulation*.

DIASTOMO'SIS. (From διαςομοω, to dilate.) Any dilatation, or dilating instrument.

DIASTRE'MMA. (From διαςρεφω, to turn aside.) *Diastrophe*. A distortion of any limb or part.

DIA'STROPHE. See *Diastremma*.

DIA'TASIS. (From διατεινω, to distend.) The extension of a fractured limb, in order to reduce it.

DIATECOLI'THUM. (From δια, and τηκολιθος, the Jew's stone.) An antidote containing lapis judiacus.

DIATERE'SIS. (From δια, and τερεω, to perforate.) A perforation or aperture.

DIATERE'TICA. (From δια, and τερεω, to preserve.) Medicines which preserve health and prevent disease.

DIATE'SSARON. (From δια, and τεσσαρες, four.) A medicine compounded of four simple ingredients.

DIATE'TTIGUM. (From δια, and τεττιγων, a grasshopper.) A medicine in the composition of which were grasshoppers, given as an antidote to some nephritic complaints by Æginetus.

DIA'THESIS. (From διατιθημι, to dispose.)

Any particular state of the body: thus, in inflammatory fever, there is an inflammatory diathesis, and, during putrid fever, a putrid diathesis.

DIATHE'SMUS. (From διαθεω, to run through.) A rupture through which some fluid escapes.

DIATRAGACA'NTHUM. (From δια, and τραγακανθα, tragacanth.) A medicine composed of gum-tragacanth.

DIA'TRIUM. (From δια, and τρεις, three.) A medicine composed of three simple ingredients.

DIAXYLA'LOES. (From δια, and ξυλαλοη, the lignum aloes.) A medicine in which is lignum aloes.

DIAZO'MA. (From διαξωννυμι, to surround; because it surrounds the cavity of the thorax.) The diaphragm.

DIAZO'STER. (From διαξωννυμι, to surround; because when the body is girded, the belt usually lies upon it.) A name of the twelfth vertebra of the back.

DICENTE'TUM. (From δια, and κεντεω, to stimulate.) A pungent or stimulating wash for the eyes.

DICHASTE'RES. (From διχαζω, to divide, because they divide the food.) The name of the foreteeth.

DICHOPHY'IA. (From διχα, double, and φυω, to grow.) A distemper of the hairs, in which they split and grow forked.

DICHOTOMUS. (From δις, twice, and τεμνω, to cut; that is, cut into two.) Dichotomous or bifurcated. Applied to stems, styles, &c. which are forked or divided into two.

DICHROITE. A species of iolite.

DICOTYLEDONES. Two cotyledons. See *Cotyledon.*

DICROTIC. (*Dicroticus;* from δις, twice, and κρουω, to strike.) A term given to a pulse in which the artery rebounds after striking, so as to convey the sensation of a double pulsation.

DICTAMNI'TES. (From δικταμνος, dittany.) A wine medicated with dittany.

DICTA'MNUS. (From *Dictamnus*, a city in Crete, on whose mountains it grows.) The name of a genus of plants in the Linnæan system. Class, *Decandria;* Order, *Monogynia.* Dittany.

DICTAMNUS ALBUS. White fraxinella, or bastard dittany. *Fraxinella. Dictamnus albus—foliis pinnatis, caule simplici,* of Linnæus. The root of this plant is the part directed for medicinal use; when fresh, it has a moderately strong, not disagreeable smell. Formerly it was much used as a stomachic, tonic, and alexipharmic, and was supposed to be a medicine of much efficacy in removing uterine obstructions and destroying worms; but its medicinal powers became so little regarded by modern physicians, that it had fallen almost entirely into disuse, till Baron Stoerck brought it into notice, by publishing several cases of its success, viz. in tertian intermittents, worms, (lumbrici,) and menstrual suppressions. In all these cases he employed the powdered root to the extent of a scruple twice a-day. He also made use of a tincture, prepared of two ounces of the fresh root digested in 14 ounces of spirit of wine; of this 20 to 50 drops two or three times a-day, were successfully employed in epilepsies, and, when joined with steel, this root, we are told, was of great service to chlorotic patients. The dictamnus undoubtedly, says Dr. Woodville, is a medicine of considerable power; but notwithstanding the account of it given by Stoerck, who seems to have paid little attention to its modus operandi, we may still say with Haller, "*nondum autem vires prodignitate exploratus est,*" and it is now fallen into disuse.

DICTAMNUS CRETICUS. See *Origanum dictamnus.*

DIDYMÆ'A. (From διδυμος, double.) A cataplasm; so called by Galen, from the double use to which he puts it.

DI'DYMI. (From διδυμος, double.) Twins. An old name of the testicles, and two eminences of the brain, from their double protuberance.

DIDYNAMIA. (From δις, twice, and δυναμις, power, two powers.) A name of a class in the sexual system of plants, consisting of those with hermaphrodite flowers, which have four stamina, two of which are long and two short.

DIECBO'LIUM. (From δια, and εκβαλλω, to cast out.) A medicine causing an abortion.

DIELE'CTRON. (From δια, and ελεκτρον, amber.) A name of a troche, in which amber is an ingredient.

DIEMERBROECK, ISBRAND, was born near Utrecht, in 1609. After graduating at Angers, he went to Nimeguen in 1636, and for some years continued freely attending those who were ill of the plague, which raged with great violence, and of which he subsequently published an account. This obtained him much credit: and in 1642 he was made professor extraordinary in medicine at Utrecht; when he gave lectures on that subject, as well as on anatomy, which rendered him very popular. He received also other distinctions at that university, and continued in high esteem till his death in 1674. He was author besides of a system of anatomy, and several other works in medicine and surgery; part of which were published after his death by his son, especially his treatise on the measles and small-pox.

DIERVI'LLA. (Named in honour of Mr. Dierville, who first brought it from Arcadia.) See *Lonicera diervilla.*

DIET. *Diæta.* The dietetic part of medicine is no inconsiderable branch, and seems to require a much greater share of regard than it commonly meets with. A great variety of diseases might be removed by the observance of a proper diet and regimen, without the assistance of medicine, were it not for the impatience of the sufferers. However, it may on all occasions come in as a proper assistant to the cure, which sometimes cannot be performed without a due observance of the non-naturals. That food is, in general, thought the best and most conducive to long life, which is most simple, pure, and free from irritating qualities, and such as approaches nearest to the nature of our own bodies in a healthy state, or is capable of being easiest converted into their substance by the vis vitæ, after it has been duly prepared by the art of cookery; but the nature, composition, virtues, and uses of particular aliments can never be learnt to satisfaction, without the assistance of practical chemistry.

DIET DRINK. An alterative decoction employed daily in considerable quantities, at least from a pint to a quart. The decoction of sarsaparilla and mezereon, the Lisbon diet drink, is the most common and most useful.

DIETE'TIC. *Dieteticus.* That part of medicine which considers the way of living with relation to food, or diet, suitable to any particular case.

DIE'XODOS. (From δια, and εξοδος, a way to pass out.) *Diodos.* In Hippocrates it means evacuation by stool.

DIFFLA'TIO. (From *difflo*, to blow away.) Perspiration.

DIFFUSUS. Diffused; spreading. Applied to panicles and stems. *Panicula diffusa,* that is lax and spreading; as in *Saxifraga umbrosa;* the London pride, so common in our gardens;

and many grasses, especially the common cultivated oat. The *Bunias kakile*, or sea rocket, has the *caulis diffusus*.

DIGA'STRICUS. (From δις, twice, and γαστηρ, a belly; so called from its having two bellies.) *Biventer maxillæ* of Albinus. *Mastoido-hygenien* of Dumas. A muscle situated externally between the lower jaw and *os hyoides*. It arises, by a fleshy belly, from the upper part of the processus mastoideus, and descending, it contracts into a round tendon, which passes through the stylohyoideus, and an annular ligament which is fastened to the os hyoides: then it grows fleshy again, and ascends towards the middle of the edge of the lower jaw, where it is inserted. Its use is to open the mouth by pulling the lower jaw downwards and backwards; and when the jaws are shut, to raise the larynx, and consequently the pharynx, upwards, as in deglutition.

DIGERE'NTIA. (From *digero*, to digest.) Medicines which promote the secretion of proper pus in wounds and ulcers.

DIGESTER. A strong and tight iron kettle or copper, furnished with a valve of safety in which bodies may be subjected to the vapour of water, alkohol, or æther, at a pressure above that of the atmosphere.

DIGESTION. (*Digestio*; from *digero*, to dissolve.)

1. An operation in chemistry and pharmacy, in which such matters as are intended to act slowly on each other, are exposed to a heat, continued for some time.

2. In physiology, the change that the food undergoes in the stomach, by which it is converted into chyme.

"The immediate object of digestion is the formation of chyle, a matter destined for the reparation of the continual waste of the animal economy. The digestive organs contribute also in many other ways to nutrition.

If we judge of the importance of a function by the number and variety of its organs, digestion ought to be placed in the first rank; no other function of the animal economy presents such a complicated apparatus.

There always exists an evident relation between the sort of aliment proper for an animal and the disposition of its digestive organs. If, by their nature, the aliments are very different from the elements which compose the animal: if, for example, it is graminivorous, the dimensions of the apparatus will be more complicated, and more considerable; if, on the contrary, the animal feeds on flesh, the digestive organs will be fewer and more simple, as is seen in the carnivorous animals. Men, called to use equally animal and vegetable aliments, keeps a mean between the graminivorous and carnivorous animals, as to the disposition and complication of his digestive apparatus, without deserving, on that account, to be called omnivorous.

We may represent the digestive apparatus as a long canal differently twisted upon itself, wide in certain points, narrow in others, susceptible of contracting or enlarging its dimensions, and into which a great quantity of fluids are poured by means of different ducts. The canal is divided into many parts by anatomists;

1. The mouth.
2. The pharynx.
3. The œsophagus.
4. The stomach.
5. The small intestines.
6. The great intestines.
7. The anus.

Two membranous layers form the sides of the digestive canal in its whole length. The inner layer, which is intended to be in contact with the aliments, consists of a mucous membrane, the appearance and structure of which vary in every one of the portions of the canal, so that it is not the same in the pharynx as in the mouth, nor is it in the stomach like what it is in the œsophagus, &c. In the lips and the anus this membrane becomes confounded with the skin. The second layer of the sides of the digestive canal is muscular; it is composed of two layers of fibres, one longitudinal, the other circular. The arrangement, the thickness, the nature of the fibres which enter into the composition of these strata are different, according as they are observed in the mouth, in the œsophagus, or in the large intestine, &c. A great number of blood-vessels go to, or come from the digestive canal; but the abdominal portion of this canal receives a quantity incomparably greater than the superior parts. This presents only what are necessary for its nutrition, and the inconsiderable secretion, of which it is the seat; whilst the number and the volume of the vessels that belong to the abdominal portion show that it must be the agent of a considerable secretion. The chyliferous vessels arise exclusively from the small intestine.

As to the nerves, they are distributed to the digestive canal in an order inverse to that of the vessels; that is, the cephalic parts, *cervical* and *pectoral*, receive a great deal more than the abdominal portion, the stomach excepted, where the two nerves of the eighth pair terminate. The other parts of the canal scarcely receive any branch of the cerebral nerves. The only nerves that are observed, proceed from the *subdiaphragmatic* ganglions of the great sympathetic. We will see, farther on, the relation that exists between the mode of distribution of the nerves, and the functions of the superior and inferior portions of the digestive canal.

The bodies that pour fluids into the digestive canal, are,

1. The *digestive mucous membrane.*
2. *Isolated follicles* that are spread in great number in the whole length of this membrane.
3. The *agglomerated follicles* which are found at the isthmus of the throat, between the *pillars* of the *velum* of the palate, and sometimes at the junction of the œsophagus and the stomach.
4. The *mucous glands* which exist in a greater or less number in the sides of the cheeks, in the roof of the palate around the œsophagus.
5. The *parotid*, the *submaxillary*, and *sublingual glands*, which secrete the saliva of the mouth, the liver, and the pancreas; the first of which pours the bile, the second the pancreatic juice, by distinct canals, into the superior part of the small intestine, called duodenum.

All the digestive organs contained in the abdominal cavity are immediately covered, more or less completely, by the serous membrane called the peritonæum. This membrane, by the manner in which it is disposed, and by its physical and vital properties, is very useful in the act of digestion, by preserving to the organs their respective relations, by favouring their changes of volume, by rendering easy the sliding motions which they perform upon each other, and upon the adjoining parts.

The surface of the mucous digestive membrane is always lubrified by a glutinous adhesive matter, more or less abundant than is seen in greatest quantity where there exist no follicles,—a circumstance which seems to indicate that these are not the only secreting organs. A part of this matter, to which is given generally the name of *mucus*, continually evaporates, so that there exists habitually a certain quantity of vapours in all the points of the digestive canal. The chemical nature of this substance, as taken at the intestinal surface, is still very little known. It is transparent, with a light grey tint; it adheres to the membrane which forms it; its taste is salt, and its acidity is shown by the re-agents: its formation still continues some time after death. That which is formed in the mouth, in the pharynx, and in the œsophagus, goes into the stomach mixed with the saliva, and the fluids of the mucous glands, by movements of deglutition, which succeed each other at near intervals. According to this detail, it would appear that the stomach ought to contain, after it has been some time empty of aliments, a considerable quantity of a mixture of mucus, of saliva, and follicular fluid. This observation is not proved, at least in the greatest number of individuals. However, in a number of persons, who are evidently in a particular state, there exist, in the morning, in the stomach, many ounces of this mixture. In certain cases it is foamy, slightly troubled, very little viscous, holding suspended some flakes of mucus; its taste is quite acid, not disagreeable, very sensible in the throat, acting upon the teeth, so as to diminish the polish of their surface, and rendering their motion upon each other more difficult. This liquid reddens paper stained with turnsol.

In the same individual, in other circumstances, and with the same appearances as to colour, transparency, and consistency, the liquid of the stomach had no savour, nor any acid property; it is a little salt: the solution of potassa, as well as the nitric and sulphuric acids, produced in it no apparent change.

When we examine the dead bodies of persons killed by accident, the stomach not having received any aliments nor drink for some time, this organ contains only a very few acid mucosities adhering to the coats of the stomach, part of which, in the pyloric portion of that viscus, appears reduced to chyme. It is, then, very probable, that the liquid which ought to be in the stomach is digested by this viscus as an alimentary substance, and that this is the reason why it does not accumulate there.

In animals the organisation of which approaches to that of man, such as dogs and cats, there is no liquid found in the stomach after one, or many days of complete abstinence; there is seen only a small quantity of viscous mucosity adhering to the sides of the organ, towards its *splenic* extremity. This matter has the greatest analogy, both chemical and physical, with that which is found in the stomach of man. But, if we make these animals swallow a body which is not susceptible of being digested, as a pebble for example, there forms, after some time, in the cavity of the stomach, a certain quantity of an acid liquid mucous of a greyish colour, sensibly salt, which, in its composition, is nearly the same as that found sometimes in man.

This liquid, resulting from the mixture of the mucosities of the mouth, of the pharynx, of the œsophagus and the stomach, with the liquid secreted by the follicles of the same parts and with the saliva, has been called by physiologists the *gastric juice*, and to which they have attributed particular properties.

In the small intestine there is also formed a great quantity of mucous matter, which rests habitually attached to the sides of the intestine; it differs little from that of which we have spoken above; it is viscid, tough, and has a salt and acid savour; it is renewed with great rapidity. If the mucous membrane of this intestine is laid bare, in a dog, and the layer of mucous absorbed by a sponge, it will appear again in a minute. This observation may be repeated as often as we please, until the intestine becomes inflamed by the contact of the air, and foreign bodies.

The mucus of the stomach penetrates into the cavity of the small intestine only under the form of a pulpous matter, greyish and opaque, which has all the appearance of a particular chyme.

It is at the surface of this same portion of the digestive canal that the bile is delivered as well as the liquid secreted by the pancreas. In animals, such as dogs, the flowing of these liquids takes place at intervals, that is, about twice in a minute, there is seen to spring from the orifice of the ductus choledochus, or biliary canal, a drop of bile, which immediately spreads itself uniformly in a sheet upon the surrounding parts, which are already impregnated with it; there is, also, constantly found a certain quantity of bile in the small intestine.

The flowing of the liquid formed by the pancreas takes place much in the same manner, but it is much slower; sometimes a quarter of an hour passes before a drop of this fluid springs from the orifice of the canal which pours it into the intestine.

The different fluids deposited in the small intestine, which are, the chymous matter that comes from the stomach, the mucus, the follicular fluid, the bile, and the pancreatic liquid, all mix together; but, on account of its properties, and perhaps of its proportions, the bile predominates, and gives to the mixture its proper taste and colour. A great part of this mixture descends towards the large intestine, and passes into it; in this passage, it becomes more consistent, and the clear yellow colour which it had before becomes dark, and afterwards greenish. There are, however, in this respect, strong individual differences.

In the large intestine, the mucous and follicular secretion appears less active than in the small intestine; the mixture of fluids which comes from the small intestine acquires in it more consistence; it contracts a fœtid odour, analogous to that of ordinary excrements; it has, besides, the appearance of it, by its colour, odour, &c.

The knowledge of these facts enables us to understand how a person who uses no aliments can continue to produce excrements, and how, in certain diseases, their quantity is very considerable, though the sick person has been long deprived of every alimentary substance, even of a liquid kind. Round the anus exist follicles, which secrete a fatty matter of a singularly powerful odour.

We find gas almost always in the intestinal canal; the stomach contains only very little. The chemical nature of these gases has not yet been examined with care; but as the saliva that we swallow is always more or less impregnated with atmospheric air, it is probably the atmospheric air, more or less changed, which is found in the stomach. At least, it contains carbonic acid. The small intestine contains only a small quantity of gas; it is a mixture of carbonic acid, of azote and hydrogen. The large intestine contains carbonic acid, azote, and hydrogen, sometimes carbureted, sometimes sulphureted. Twenty-three per cent. of this gas was found in the rectum of an individual, whose large intestine contained no excrement.

The muscular layer of the digestive canal deserves to be remarked, in respect to the different modes of contraction it presents. The lips, the jaws, in most cases the tongue, the cheeks, are moved by a contraction, entirely like that of the muscles of locomotion. The roof of the palate, the pharynx, the œsophagus, and the tongue in certain particular circumstances, offer many motions, which have a manifest analogy with muscular contraction, but which are very different from it because they take place without the participation of the will.

This does not imply that the motions of the parts just named are beyond the influence of the nerves; experience proves directly the contrary. If, for example, the nerves that come to the œsophagus are cut, this tube is deprived of its contractile faculty.

The muscles of the velum of the palate, those of the pharynx, the superior two-thirds of the œsophagus, scarcely contract like digestive organs, but when they act in permitting substances to pass from the mouth into the stomach. The inferior third of the œsophagus presents a phenomenon which is important to be known: this is an alternate motion of contraction and relaxation which exists in a constant manner. The contraction commences at the union of the *superior two-thirds* of the canal with the *inferior third*; it is continued, with a certain rapidity, to the insertion of the œsophagus into the stomach: when it is once produced, it continues for a time, which is variable; its mean duration is, at least, thirty seconds. Being so contracted in its inferior third, the œsophagus is hard and elastic, like a cord strongly stretched. The relaxation which succeeds the contraction happens all at once, and simultaneously in all the contracted fibres; in certain cases, however, it seems to take place from the superior to the inferior fibres. In the state of relaxation, the œsophagus presents a remarkable flaccidity, which makes a singular contrast with its state of contraction.

This motion of the œsophagus depends on the nerves of the eighth pair. When these nerves of an animal are cut, the œsophagus no longer contracts, but neither is it in the relaxed state that we have described; its fibres being separated from nervous influence, shorten themselves with a certain force, and the canal is found in an intermediate state between contraction and relaxation. The vacuity, or distention of the stomach, has an influence upon the duration and intensity of the contraction of the œsophagus.

From the inferior extremity of the stomach to the end of the intestine rectum, the intestinal canal presents a mode of contraction which differs, in almost every respect, from the contraction of the sub-diaphragmatic portion of the canal. This contraction always takes place slowly, and in an irregular manner; sometimes an hour passes before any trace of it can be perceived; at other times many intestinal portions contract at once. It appears to be very little influenced by the nervous system: for example; it continues in the stomach after the section of the nerves of the eighth pair; it becomes more active by the weakness of animals, and even by their death; in some, by this cause, it becomes considerably accelerated; it continues, though the intestinal canal is entirely separated from the body. The pyloric portion of the stomach, the small intestine, are the points of the intestinal canal where it is presented oftenest, and most constantly. This motion, which arises from the successive or simultaneous contraction of the longitudinal or circular fibres of the intestinal canal, has been differently denominated by authors: some have named it *vermicular*, others *peristaltic*, others again, *sensible organic contractility*, &c. Whatever it is, the will appears to exert no sensible influence upon it.

The muscles of the anus contract voluntarily.

The supra-diaphragmatic portion of the digestive canal is not susceptible of undergoing any considerable dilatation; we may easily see, by its structure, and the mode of contraction of its muscular coat, that it is not intended to allow the aliments to remain in its cavity, but that it is rather formed to carry these substances from the mouth into the stomach: this last organ, and the large intestine, are evidently prepared to undergo a very great distention; substances, also, which are introduced into the alimentary canal, accumulate, and remain for a time, more or less, in their interior.

The diaphragm, and the abdominal muscles, produce a sort of perpetual agitation of the digestive organs contained in the abdominal cavity; they exert, upon them, a continual pressure, which becomes sometimes very considerable.

The digestive actions which, by their union, constitute digestion, are—

1. The apprehension of aliments.
2. Mastification.
3. Insalivation.
4. Deglutition.
5. The action of the stomach.
6. The action of the small intestines.
7. The action of the large intestines.
8. The expulsion of the fœcal matter.

All the digestive actions do not equally contribute to the production of chyle; the action of the stomach and that of the small intestines are alone absolutely necessary.

The digestion of solid food requires generally the eight digestive actions; that of drinks is much more simple; it comprehends only apprehension, deglutition, the action of the stomach, and that of the small intestine.

The mastication and deglutition of the food being effected, we have now to notice the action of the stomach on the aliment: chemical alterations will now present themselves to our examination. In the stomach the food is transformed into a matter proper to animals, which is named *chyme*.

Before showing the changes that the food undergoes in the stomach, it is necessary to know the phenomena of their accumulation in this viscus, as well as the local and general effects that result from it.

The first mouthfuls of food swallowed are easily lodged in the stomach. This organ is not much compressed by the surrounding viscera; its sides separate easily, and give way to the force which presses the alimentary bole; but its distention becomes more difficult in proportion as new food arrives, for this is accompanied by the pressing together of the abdominal viscera, and the extension of the sides of the abdomen. This accumulation takes place particularly towards the right extremity and the middle part: the pyloric half gives way with more difficulty.

Whilst the stomach is distended, its form, its relations, and even its positions, undergo alterations: in place of being flattened on its aspects, of occupying only the epigastrium and a part of the left *hypochondrium*, it assumes a round form; its great *cul de sac* is thrust into this *hypochondrium*, and fills it almost completely; the greater *curvature* descends towards the umbilicus, particularly on the left side; the pylorus, alone, fixed by a fold of the *peritonæum*, preserves its motion and its relations with the surrounding parts. On account of the resistance that the vertebral column presents behind, the posterior surface of the stomach cannot distend itself on that side: for that reason this viscus is wholly carried forward; and as the pylorus and the œsophagus cannot be displaced in this direction, it makes a motion of rotation, by which its great curve is directed a little forward; its posterior aspect inclines downwards, and its superior upwards.

Though it undergoes these changes of position and relation, it, nevertheless, preserves the recurved conoid form which is proper to it. This effect depends on the manner in which the three tunics contribute to its dilatation. The two plates of the serous membrane separate and give place to the stomach. The muscular layer suffers a real distention; its fibres are prolonged, but so as to preserve the particular form of the stomach. Lastly, the mucous membrane gives way, particularly in the points where the folds are multiplied. It will be noticed that these are found particularly along the larger curve, as well as at the splenic extremity.

The dilatation of the stomach alone produces very important changes in the abdomen. The total volume of this cavity augments; the belly juts out; the abdominal viscera are compressed with greater force; often the necessity of passing urine, or fæces, is felt. The diaphragm is pressed towards the breast, it descends with some difficulty; thence the motions of respiration, and the phenomena which depend on it, are more incommoded, such as speech, singing, &c.

In certain cases, the dilatation of the stomach may be carried so far that the sides of the abdomen are painfully distended, and respiration becomes difficult.

To produce such effects, the contraction of the œsophagus, which presses the food in the stomach, must be very energetic. We have remarked above the considerable thickness of the muscular layer of this canal, and the great number of nerves which go to it; nothing less than this disposition is necessary to account for the force with which the food distends the stomach. For more certainty the finger has only to be introduced into the œsophagus of an animal by the cardiac orifice, and the force of the contraction will be found striking.

But if the food exerts so marked an influence upon the sides of the stomach and the abdomen, they ought themselves to suffer a proportionate re-action, and tend to escape by the two openings of the stomach. Why does this effect not take place? It is generally said that the cardia and pylorus shut; but this phenomenon has not been submitted to any particular researches. Here is what Dr. Magendie's experiments have produced in this respect.

The alternate motion of the œsophagus prevents the return of the food into this cavity. The more the stomach is distended, contraction becomes the more intense and prolonged, and the relaxation of shorter duration. Its contraction generally coincides with the instant of inspiration, when the stomach is most forcibly compressed. Its relaxation ordinarily happens at the instant of expiration.

We may have an idea of this mechanism by laying bare the stomach of a dog, and endeavouring to make the food pass into the œsophagus by compressing the stomach with both hands. It will be nearly impossible to succeed, whatever force is used, if it is done at the instant when the œsophagus is contracted: but the passage will take place, in a certain degree, of itself, if the stomach is compressed at the instant of relaxation.

The resistance that the pylorus presents to the passage of the aliments is of another kind. In living animals, whether the stomach is empty or full, this opening is habitually shut, by the constriction of its fibrous ring, and the contraction of its circular fibres. There is frequently seen another constriction in the stomach, at the distance of one or two inches, which appears intended to prevent the food from reaching the pylorus; we perceive, also, irregular and peristaltic contractions, which commence at the duodenum, and are continued into the pyloric portion of the stomach, the effect of which is to press the food towards the splenic part. Besides, should the pylorus not be naturally shut, the food would have little tendency to enter it, for it only endeavours to escape into a place where the pressure is less; and this would be equally great in the small intestine as in the stomach, since it is nearly equally distributed over all the abdominal cavity.

Among the number of phenomena produced by the food in the stomach, there are several, the existence of which, though generally admitted, do not appear sufficiently demonstrated; such is the diminution of the volume of the spleen, and that of the blood-vessels of the liver, or the *omenta*, &c.; such is also a motion of the stomach, which should preside over the reception of the food, distribute it equally by exerting upon it a gentle pressure, so that its dilatation, far from being a passive phenomenon, must be essentially active. Dr. Magendie has frequently opened animals the stomachs of which were filled with food; he has examined the bodies of executed persons, a short time after death, and has seen nothing favourable to these assertions.

The accumulation of food in the stomach is accompanied by many sensations, of which it is necessary to take account;—at first, it is an agreeable feeling, or the pleasure of a want satisfied. Hunger is appeased by degrees; the general weakness that accompanied it is replaced by an active state, and a feeling of new force. If the introduction of food is continued, we experience a sensation of fulness and satiety which indicates that the stomach is suffcently replenished; and if, contrary to this instinctive information, we still persist to make use of food, disgust and nausea soon arrive, and they are very soon followed by vomiting. These different impressions must not be attributed to the volume of the aliments alone. Every thing being equal in other respects, food very nutritive occasions, more promptly, the feeling of satiety. A substance which is not very nourishing does not easily calm hunger, though it is taken in great quantity.

The mucous membrane of the stomach, then, is endowed with considerable sensibility, since it distinguishes the nature of substances which come in contact with it. This property is very strongly marked if an irritating poisonous substance is swallowed; intolerable pain is then felt. We also know that the stomach is sensible to the temperature of food.

We cannot doubt that the presence of the aliments of the stomach causes a great excitement, from the redness of the mucous membrane, from the quantity of fluid it secretes, and the volume of vessels directed there; but this is favourable to chymification. This excitement of the stomach influences the general state of the functions.

The time that the aliments remain in the stomach is considerable, generally several hours; it is during this stay that they are transformed into chyme.

Changes of the Aliments in the Stomach:—It is more than an hour before the food suffers any apparent change in the stomach, more than what results from the perspiratory and mucous fluids with which they are mixed, and which are continually renewed.

The stomach is uniformly distended during this time; but the whole extent of the pyloric portion afterwards contracts, particularly that nearest the splenic portion, into which the food is pressed. Afterwards, there is nothing found in the pyloric portion but chyme, mixed with a small quantity of unchanged food.

The best authors have agreed to consider the chyme as a homogeneous substance, pultaceous, greyish, of a sweetish taste, insipid, slightly acid, and preserving some of the properties of the food. This description leaves much to be explained.

The result of Dr. Magendie's experiments are as follows:

A. There are as many sorts of chyme as there are different sorts of food, if we judge by the colour, consistence, appearance, &c.; as we may easily ascertain, by giving different simple alimentary substances to dogs to eat, and killing them during the operation of digestion. He frequently found the same result in man, in the dead bodies of criminals, or persons dead by accident.

B. Animal substances are generally more easily and completely changed than vegetable substances. It frequently happens that these last traverse the whole intestinal canal without changing their apparent properties. He has frequently seen in the rectum, and in the small intestine, the vegetables which are used in soup, spinage, sorrel, &c., which had preserved the most part of their properties: their colour alone appeared sensibly changed by the contact of the bile.

Chyme is formed particularly in the pyloric portion. The food appears to be introduced slowly into it, and during the time they remain they undergo transformation. The Doctor believes, however, that he has observed frequently chymous matter at the surface of the mass of aliments which fill the splenic portion; but the aliments in general preserve their properties in this part of the stomach.

It would be difficult to tell why the pyloric portion is better adapted to the formation of chyme than the rest of the stomach; perhaps the great number of follicles that are seen in it modify the quantity or the nature of the fluid that is there secreted. The transformation of alimentary substances into chyme takes place generally from the superficies to the centre. On the surface of portions of food swallowed, there is formed a soft layer easy to be detached. The substances seem to be attacked and corroded by a reagent capable of dissolving them. The white of a hard egg, for instance, becomes in a little time as if plunged in vinegar, or in a solution of potassa.

C. Whatever is the alimentary substance employed, the chyme has always a sharp odour and taste, and reddens paper coloured with turnsol.

D. There is only a small quantity of gas found in the stomach during the formation of chyme; sometimes there exists none. Generally it forms a small bubble at the superior part of the splenic portion. Once only in the body of a criminal a short time after death, he gathered with proper precautions a quantity sufficient to be analysed. Chevreuil found it composed of:

Oxygen,	11.00
Carbonic acid,	14.00
Pure hydrogen,	3.55
Azote,	71.45
Total,	100.00

There is rarely any gas found in the stomach of a dog. We cannot then believe, with Professor Chaussier, that we swallow a bubble of air at every motion of deglutition, which is pressed into the stomach by the alimentary bole. Were it so, there ought to be found a considerable quantity of air in this organ after a meal: now the contrary is to be seen.

E. There is never a great quantity of chyme accumulated in the pyloric portion: the most that the Doctor ever saw in it was scarcely equal in volume to two or three ounces of water. The contraction of the stomach appears to have an influence upon the production of chyme. The following is what he observed in this respect. After having been some time immoveable, the extremity of the duodenum contracts, the pylorus and the pyloric portion contract also; this motion presses the chyme towards the splenic portion; but it afterwards presses it in a contrary direction, that is, after being distended, and having permitted the chyme to enter again into its cavity, the pyloric portion contracts from left to right, and directs the chyme towards the duodenum, which immediately passes the pylorus and enters the intestine.

The same phenomenon is repeated a certain number of times, but it stops to begin again, after a certain time. When the stomach contains much food, this motion is limited to the parts of the organ nearest the pylorus; but in proportion as it becomes empty, the motion extends farther, and is seen even in the splenic portion when the stomach is almost entirely empty. It becomes generally more strong about the end of chymification. Some persons have a distinct feeling of it at this moment.

The pylorus has been made to play a very important part in the passage of the chyme from the stomach to the intestine. It judges, they say, of the chymification of the food; it opens to those that have the required qualities, and shuts against those that have not. However, as we daily observe substances not digestible traverse it easily, such as stones of cherries, it is added, that becoming accustomed to a substance not chymified, which presents itself repeatedly, it at last opens a passage. These considerations, consecrated in a certain degree by the word *pylorus*, *a porter*, may please the fancy, but they are purely hypothetical.

F. All the alimentary substances are not transformed into chyme with the same promptitude.

Generally the fat substances, the tendons, the cartilages, the concrete albumen, the mucilaginous and sweet vegetables, resist more the action of the stomach than the caseous, fibrinous, and glutinous substances. Even some substances appear refractory: such as the bones, the epidermis of fruits, their stones, and whole seeds, &c.

In determining the digestibility of food, the volume of the portions swallowed ought to be taken into account. The largest pieces, of whatever nature, remain longest in the stomach; on the contrary, a substance which is not digestible, if it is very small, such as grape stones, does not rest in the stomach, but passes quickly with the chyme into the intestine.

In respect of the facility and quickness of the formation of chyme, it is different in every different individual. It is evident, after what has been said, that to fix the necessary time for the chymification of all the food contained in the stomach, we ought to take into account their quantity, their chemical nature, the manner in which the mastication acts upon them, and the individual disposition. However, in four or five hours after an ordinary meal, the transformation of the whole of the food into chyme is generally effected.

The nature of the chemical changes that the food undergoes in the stomach is unknown. It is not because there have been no attempts at different periods to give explanations of them more or less plausible. The ancient philosophers said that the food became putrified in the stomach; Hippocrates attributed the digestive process to coction; Galen assigned the stomach attractive, retentive, concoctive, expulsive faculties, and by their help he attempted to explain digestion. The doctrine of Galen reigned in the schools until the middle of the seventeenth century, when it was attacked and overturned by the *fermenting chemists*, who established in the stomach an *effervescence*, a particular fermentation, by means of which the food was *macerated*, *dissolved*, *precipitated*, &c.

This system was not long in repute; it was replaced by ideas much less reasonable. Digestion was supposed to be only a trituration, a bruising performed by the stomach; an innumerable quantity of little worms was supposed to attack and divide the food. Boerhaave thought he had found the truth by combining the different opinions that had reigned before him. Haller did not follow the ideas of his master; he considered digestion a simple *maceration*. He knew that vegetable and animal matters plunged into water are soon covered with soft homogeneous layer; he believed that the food underwent a like change, by macerating in the saliva and fluids secreted by the stomach.

Reaumur and Spallanzani made experiments on animals, and demonstrated the falsity of the ancient systems; they showed that food, contained in hollow metallic balls pierced with small holes, was digested the same as if it was free in the cavity of the stomach. They proved that the stomach contains a particular fluid which they call *gastric juice*, and that this fluid was the principal agent of digestion; but they much exaggerated its properties, and they were mistaken when they thought to have explained digestion in considering it as a *solution*: because, in not explaining this solution, they did not explain the changes of food in the stomach.

In the formation of chyme, it is necessary to consider, 1st, The circumstances in which the food is found in the stomach. 2dly, the chemical nature of it.

The circumstances affecting the food in the stomach during its stay there are not numerous: 1st, it suffers a pressure more or less strong either from the sides of the abdomen, or from those of the stomach; 2dly, the whole is entirely moved by the motions of respiration; 3dly, it is exposed to a temperature of thirty to thirty-two degrees of Reaumur; 4thly, it is exposed to the action of the saliva, of the mucosities proceeding from the mouth and the œsophagus, as well as the fluid secreted by the mucous membrane of the stomach.

It will be remembered that this fluid is slightly viscous, that it contains much water, mucus, salts, with a base of soda and ammonia, and lactic acid of Berzelius.

With regard to the nature of the food, we have already seen how variable it is, since all the immediate principles, animal or vegetable, may be carried into the stomach in different forms and proportions, and serve usefully in the formation of chyme. Now, making allowance for the nature of the food, and the circumstances in which it is placed in the stomach, shall we be able to account for the known phenomena of the formation of chyme? The temperature of thirty to thirty-two degrees, R. = 100 to 104 F.; the pressure, and the tossing that the food sustains, cannot be considered as the principal cause of its transformation into chyme; it is probable that they only co-operate in this; the action of the saliva and that of the fluid secreted in the stomach remain; but after the known composition of the saliva it is hardly possible that it can attack and change the nature of the food; at most, it can only serve to divide, to imbibe it in such a manner as to separate its particles: it must then be the action of the fluid formed by the internal membrane of the stomach. It appears certain that this fluid, in acting chemically upon the alimentary substances, dissolves them from the surface towards the centre.

To produce a palpable proof of it, with this fluid of which we speak, there have been attempts made to produce what is called in physiology, *artificial digestions*, that is, after having macerated food, it is mixed with gastric juice, and then exposed in a tube or any other vase to a temperature equal to that of the stomach. Spallanzani advanced that these digestions succeeded, and that the food was reduced to chyme; but, according to the researches of de Montegre, it appears that they are not; and that, on the contrary, the substances employed undergo no alteration analogous to chymification; this is agreeable to experiments made by Reaumur. But because the gastric juice does not dissolve the food when put with it into a tube, we ought not to conclude that the same fluid cannot dissolve the food when it is introduced into the stomach; the circumstances are indeed far from being the same: in the stomach, the temperature is constant, the food is pressed and agitated, and the saliva and gastric juice are constantly renewed; as soon as the chyme is formed, it is carried away and pressed in the duodenum. Nothing of this takes place in the tube or vase which contains the food mixed with gastric juice; therefore, the want of success in artificial digestions, proves nothing which tends to explain the formation of chyme.

But how does it happen that the same fluid can act in a manner similar upon the great variety of alimentary substances, animal and vegetable? The acidity which characterizes it, though fit to dissolve certain matters, as albumen, for example, would not be suitable for dissolving fat.

To this it may be answered, that nothing proves the gastric juice to continue always the same; the small number of analyses that have been made of it demonstrate, on the contrary, that it presents considerable varieties in its properties. The contact of different sorts of food upon the mucous membrane of the stomach may possibly influence its composition; it is at least certain, that this varies in the different animals. For example, that of man is incapable of acting on bones; it is well known that the dog digests these substances perfectly.

Generally speaking, the action by which the chyme is formed prevents the re-action of the constituent elements of the food upon each other: but this effort takes place only in good digestions; in bad digestion, fermentation, and even putrefaction may take place: this may be suspected by the great quantity of inodorous gases that are developed in certain cases, and the sulphureted hydrogen which is disengaged in others.

The nerves of the eighth pair have long been considered to direct the act of chymification: in fact, if these nerves are cut, or tied in the neck, the matters introduced into the stomach undergo no alteration. But the consequence (says Dr. Magendie) that is deduced from this fact does not appear to me to be rigorous. Is not the effect produced upon the stomach by the injury done to respiration, confounded here with the direct influence of the section of the nerves of the eighth pair upon this organ? I am inclined to believe it; for, as I have many times done, if the two-eighth pairs be cut in the breast *below* the branches which go to the lungs, the food which is introduced afterwards into the stomach is transformed into chyme, and ultimately furnishes an abundant chyle.

Some persons imagine that electricity may have an influence in the production of chyme, and that the nerves we mention may be the conductors: there is no established fact to justify this conjecture. The most probable use of the nerves of the eighth pair is, to establish intimate relations between the stomach and the brain, to give notice whether any noxious substances have entered along with the food, and whether they are capable of being digested.

In a strong person, the operation of the formation of chyme takes place without his knowledge; it is merely perceived that the sensation of fulness, and the difficulty of respiration produced by the distention of the stomach, disappear by degrees; but frequently, with people of a delicate temperament, digestion is accompanied with feebleness in the action of the senses, with a general coldness, and slight shiverings; the activity of the mind diminishes, and seems to become drowsy, and there is a disposition to sleep. The vital powers are then said to be concentrated in the organ that acts, and to abandon for an instant the others. To those general effects are joined the production of the gas that escapes by the mouth, a feeling of weight, of heat, of giddiness, and sometimes of burning, followed by an analogous sensation along the œsophagus, &c. These effects are felt particularly towards the end of the chymification. It does not appear, however, that these laborious digestions are much less beneficial than the others.

From the stomach the food is received into the *small intestine*, which is the longest portion of the digestive canal; it establishes a communication between the stomach and the large intestine. Not being susceptible of much distention, it is twisted a great many times upon itself, being much longer than the place in which it is contained. It is fixed to the vertebral column by a fold of the peritonæum, which limits, yet aids its motions; its longitudinal and circular fibres are not separated as in the stomach; its mucous membrane, which presents many villi, and a great number of mucous follicles, forms irregular circular folds, the number of which are greater in proportion as the intestine is examined nearer the pyloric orifice: these folds are called *valvulæ conniventes*.

The small intestine receives many blood-vessels; its nerves come from the *ganglions* of the *great sympathetic*. At its internal surface the numerous orifices of the chyliferous vessels open.

This intestine is divided into three parts, called the *duodenum*, *jejunum*, and *ileum*. The mucous membrane of the small intestine, like that of the stomach, secretes abundance of mucus; viscous, thready, of a salt taste, and reddens strongly turnsol paper; all which properties are also in the liquid secreted by the stomach. Haller gave this fluid the name of *intestinal juice;* the quantity that is formed in twenty-four hours he estimated at eight pounds.

Not far from the gastric extremity of this intestine is the common orifice of the biliary and pancreatic canals, by which the fluid secreted by the liver and the pancreas flow into the intestinal cavity. If the formation of the chyme is still a mystery, the nature of the phenomena that take place in the small intestine are little better known.

In the experiments which have been made on dogs and rabbits, the chyme is seen to pass from the stomach into the duodenum. The phenomena are these. At intervals, more or less distant, a contractile motion commences towards the middle of the duodenum; it is propagated rapidly to the site of the pylorus: this ring contracts itself, as also the pyloric part of the stomach; by this motion, the matters contained in the duodenum are pressed back towards the pylorus, where they are stopped by the valve, and those that are found in the *pyloric* part, are partly pressed towards the *splenic* part; but this motion, directed from the intestine towards the stomach, is very soon replaced by another in a contrary direction, that is, which propagates itself from the stomach towards the duodenum, the result of which is to make a considerable quantity of chyme pass the pylorus.

This fact seems to indicate that the valve of the pylorus serves as much to prevent the matters contained in the small intestine from flowing back into the stomach, as to retain the chyme and the food in the cavity of this organ.

The motion that we have described, is generally repeated many times following, and modified as to the rapidity, the intensity of the contraction, &c.; it then ceases to begin again after some time. It is not very marked in the first moments of the formation of the chyme; the extremity only of the pyloric part participates in it. It augments in proportion as the stomach becomes empty; and, towards the end of chymification, it often takes place over the whole stomach. It is not suspended by the section of the nerves of the eighth pair.

Thus the entrance of chyme into the small intestine is not perpetual. According as it is repeated, the chyme accumulates in the first portion of the intestine, it distends its sides a little, and presses into the intervals of the valves; its presence very soon excites the organ to contract, and by this means one part advances into the intestine; the other remains attached to the surface of its membrane, and afterwards takes the same direction. The same phenomenon continues down to the large intestine; but, as the duodenum receives new portions of the chyme, it happens at last that the small intestine is filled in its whole length with this matter. It is observed only to be much less abundant near the *cæcum* than at the pyloric extremity.

The motion that determines the progress of the chyme through the small intestine, has a great analogy with that of the pylorus: it is irregular, returns at periods which are variable, is sometimes in one direction, sometimes in another, takes place sometimes in many parts at once; it is always slow, more or less; it causes relative changes among the intestinal circumvolutions. It is beyond the influence of the will.

We should form a false idea of it were we merely to examine the intestine of an animal recently dead; it has then a much greater activity than during life. Nevertheless, in weak digestions it appears to acquire more than ordinary energy and velocity.

In whatever manner this motion takes place, the chyme appears to move very slowly in the small intestine: the numerous valves that it contains, the multitude of asperities that cover the mucous membrane, the many bendings of the canal, are so many circumstances that ought to contribute to retard its progress, but which ought to favour its mixture with the fluids contained in the intestine, and the production of the chyle which results from it.

Changes that the chyme undergoes in the small intestine.—It is only about the height of the orifice of the choledochus and pancreatic canal that the chyme begins to change its properties. Before this, it preserves its colour, its semi-fluid consistence, its sharp odour, its slightly acid savour; but, in mixing with the bile and the pancreatic juice, it assumes new qualities: its colour becomes yellowish, its taste bitter, and its sharp odour diminishes much. If it proceeds from animal or vegetable matters, which contained grease or oil, irregular filaments are seen to form here and there upon its surface; they are sometimes flat, at other times rounded, attach themselves quickly to the surface of the valve, and appear to consist of crude chyle. This matter is not seen when the chyme proceeds from matter that contained no fat; it is a greyish layer, more or less thick, which adheres to the mucous membrane, and appears to contain the elements of chyle. The same phenomena are observed in the *two superior thirds* of the small intestine: but in the *inferior third*, the chymous matter is more consistent; its yellow colour becomes more deep; it ends sometimes by becoming of a greenish brown, which pierces through the intestinal parietes, and gives an appearance to the *ileum*, distinct from that of the *duodenum* and *jejunum*. When it is examined near the *cæcum*, there are few or no whitish chylous striæ seen; it seems, in this place, to be only the remainder of the matter which has served in the formation of the chyle.

After what has been said above, upon the varieties that the chyme presents, we may understand that the changes it undergoes in the small intestine are variable according to its properties; in fact, the phenomena of digestion in the small intestine, vary according to the nature of the food. The chyme, however, preserves its acid property; and if it contains small quantities of food or other bodies that have resisted the action of the stomach, they traverse the small intestine without undergoing any alteration. The same phenomena appear when the same substances have been used. Dr. Magendie has ascertained this fact upon the bodies of two criminals who, two hours before death, had taken an ordinary meal, in which they had eaten the same food nearly in equal quantity; the matters contained in the stomach, the chyme in the pyloric portion and in the small intestine, appeared to him exactly the same as to consistence, colour, taste, odour, &c.

There is generally gas found in the small intestine during the formation of chyle. Drs. Magendie and Chevreuil have made experiments upon the bodies of criminals opened shortly after death, and who being young and vigorous presented the most favourable conditions for such researches. In a subject of twenty-four years, who had eaten, two hours before his death, bread, and some Swiss cheese, and drank water reddened with wine, they found in the small intestine:

Oxygen	0.00
Carbonic acid	24.39
Pure hydrogen	55.53
Azote	20.08
Total	100.00

In a second subject, aged twenty-three years, who had eaten of the same food at the same hour, and whose punishment took place at the same time:

Oxygen	0.00
Carbonic acid	40.00
Pure hydrogen	51.15
Azote	8.85
Total	100.00

In a third experiment, made upon a young man of twenty-eight years, who, four hours before death had eaten bread, beef, lentiles, and drank red wine, they found in the same intestine:

Oxygen	0.00
Carbonic acid	25.00
Pure hydrogen	8.40
Azote	66.60
Total	100.00

They never observed any other gases in the small intestine. These gases might have different origins. They might possibly come from the stomach with the chyme; or they were perhaps, secreted by the intestinal mucous membrane; they might arise from the reciprocal action of the matters contained in the intestine; or perhaps they might come from all these sources at once.

However, the stomach contains oxygen, and very little hydrogen, whilst they have almost always found much hydrogen in the small intestine, and never any oxygen. Besides, it is a daily observation, that the little gas that the stomach contains is generally passed by the mouth towards the end of chymification, probably, because at this instant it can more easily advance into the œsophagus.

The probability of the formation of gases by the secretion of the mucous membrane could not be at all admissible, except for carbonic acid, which seems to be formed in this manner in respiration. With regard to the action of matters contained in the intestine, Dr. Magendie says he has many times seen the chymous matter let bubbles of gas escape very rapidly. This took place from the orifice of the ductus choledochus to the commencement of the *ileum*; there was no trace of it perceived in this last intestine, nor in the superior part of the duodenum, nor the stomach. He made this observation again upon the body of a criminal four hours after death; it presented no traces of putrefaction.

The alteration which chyme undergoes in the small intestine is unknown; it is easily seen to be the result of the action of the bile, of the pancreatic juice, and of the fluid secreted by the mucous membrane, upon the chyme. But what is the play of the affinities in this real chemical operation, and why is the chyle precipitated against the surface of the *valvulæ conniventes*, whilst the rest remains in the intestine to be afterwards expelled? This is completely unknown.

We have learned something more of the time that is necessary for this alteration of the chyme. The phenomenon does not take place quickly: in animals, it often happens that we do not find any chyle formed three or four hours after the meal.

After what has been said, we see that in the small intestine, the chyme is divided into two parts: the one which attaches itself to the sides, and which is the chyle still impure; the other the true refuse, which is destined to be thrown into the large intestine, and afterwards entirely carried out of the body.

The manner in which drinks accumulate in the stomach differs little from that of the aliments; it is generally quicker, more equal, and more easy; probably because the liquids spread, and distend the stomach more uniformly. In the same manner as the food, they occupy more particularly its left and middle portion; the pyloric, or right extremity contains always much less.

The distention of the stomach must not, however, be carried to a great degree, for the liquid would be expelled by vomiting. This frequently happens to persons that swallow a great quantity of drink quickly. When we wish to excite vomiting in persons who have taken an emetic, one of the best means is to make them drink a number of glasses of liquid quickly.

The presence of drinks in the stomach produces local phenomena like those which take place from the *accumulation of the aliments;* the same changes in the form and position of the organ, the same distention of the abdomen, the same contraction of the pylorus and the œsophagus, &c.

The general phenomena are different from those produced by the aliments: this depends on the action of the liquids upon the sides of the stomach, and the quickness with which they are carried into the blood.

Potations, in passing rapidly through the mouth and the œsophagus, preserve more than the food their proper temperature until they arrive in the stomach. We therefore prefer them to those, when we wish to experience in this organ a feeling of heat or of cold: hence arises the preference that we give to hot drinks in winter, and cold drinks in summer.

Every one knows that the drinks remain much shorter time in the stomach than the aliments; but the manner of their passage out of the viscus is still very little known. It is generally supposed that they traverse the pylorus and pass into the small intestine, where they are absorbed with the chyle; nevertheless a ligature applied round the pylorus in such a manner as to hinder it from penetrating into the duodenum, does not much retard its disappearance from the cavity of the stomach.

Alteration of drinks in the stomach.—Fluids, in respect of the alterations that they prove in the stomach, may be divided into two classes: the one sort do not form any chyme, and the other are chymified wholly or in part.

To the first class belong pure water, alcohol, sufficiently weak to be considered as a drink, the vegetable acids, &c. During its stay in the stomach, water assumes an equilibrium of temperature with the sides of this viscus: it mixes at the same time with mucus, the gastric juice, and the saliva which are found in it; it becomes muddy, and afterwards disappears slowly without suffering any other transformation. One part passes into the small intestine; the other appears to be directly absorbed. There remains after its disappearance a certain quantity of mucus, which is very soon reduced to chyme like the aliments. By observation we know that water deprived of atmospheric air, as distilled water, or water charged with a great quantity of salts, as well-water, remain long in the stomach and produce a feeling of weight.

Alkohol acts quite in a different manner. We know the impression of burning heat that it causes at first in its passage through the mouth, the pharynx, the œsophagus; and that which it excites when it enters the stomach: the effects of this action determine the contraction of this organ, irritate the mucous membrane, and augment the secretion of which it is the seat; it coagulates at the same time all the albuminous parts with which it is in contact; and as the different liquids in the stomach contain a considerable proportion of this matter, it happens that a short time after alkohol has been swallowed, there is in this viscus a certain quantity of concrete albumen. The mucus undergoes a modification analogous to that of the albumen; it becomes hard, forms irregular elastic filaments, which preserve a certain transparency.

In producing these phenomena, the alkohol mixes with the water that the saliva and the gastric juice contain; probably it dissolves a part of the elements that enter into their composition, so that it ought to be much weakened by its stay in the stomach. It disappears very quickly; its general effects are also very rapid, and drunkenness or death follow almost immediately the introduction of too great a quantity of alkohol into the stomach.

The matters coagulated by the action of the alkohol are, after its disappearance, digested like solid aliments.

Among the drinks that are reduced to chyme, some are reduced in part and some wholly.

Oil is in this last case; it is transformed, in the pyloric part, into a matter analogous in appearance with that which is drawn from the purification of oils by sulphuric acid; this matter is evidently the chyme of oil. On account of this transformation, oil is perhaps the liquid that remains longest in the stomach.

Every one knows that milk curdles soon after it is swallowed; this curd then becomes a solid aliment, which is digested in the ordinary manner. Whey only can be considered as drink.

The greatest number of drinks that we use are formed of water, or of alkohol, in which are in suspension or dissolution, immediate animal or vegetable principles, such as gelatine, albumen, osmazome, sugar, gum, fecula, colouring or astringent matters, &c. These drinks contain salts of lime, of soda, of potassa, &c.

The result of several experiments that have been made upon animals, and some observations that have been made on man, is, that there is a separation of the water and the alkohol in the stomach from the matters that these liquids hold in suspension or solution. These matters remain in the stomach, where they are transformed into chyme, like the aliments; whilst the liquids with which they were united are absorbed, or pass into the small intestine; lastly, they are conducted, as we have just now seen, in treating of water and alkohol.

Salts that are in solution in water do not abandon this liquid, and are absorbed with it. Red wine, for example, becomes muddy at first by its mixture with juices that are formed in, or carried into the stomach; it very soon coagulates the albumen of these fluids, and becomes flaky; afterwards, its colouring matter, carried perhaps by the mucus and the albumen, is deposited upon the mucous membrane: there is a certain quantity of it seen at least in the pyloric portion; the watery and alkoholic parts disappear with rapidity.

The broth of meat undergoes the same changes. The water that it contains is absorbed; the gelatine, the albumen, the fat, and probably the osmazome, remain in the stomach, where they are reduced into chyme.

Action of the small intestine upon drinks.—After what has been read, it is clear that fluids penetrate, under two forms, into the small intestine: 1st, under that of liquid; 2dly, under that of chyme.

The liquids that pass from the stomach into the intestine remain but a short time, except under particular circumstances; they do not appear to undergo any other alteration than their mixture with the intestinal juice, the chyme, the pancreatic liquid, and the bile; they do not form any sort of chyle; they are generally absorbed in the duodenum, and the commencement of the jejunum; they are rarely seen in the ilium, and still more rarely in the large intestine. It appears that this last case does not happen except in the state of sickness; for example, during the action of a purgative.

The chyme that proceeds from drinks follows the same rule, and appears to undego the same changes as that of the food; it therefore produces chyle.

Such are the principal phenomena of the digestion of drinks: we see how necessary it was to distinguish them from those that belong to the digestion of the aliments.

But we do not always digest the aliments and the drinks separately, as we have supposed; very frequently the two digestions take place at the same time.

Drink favours the digestion of the aliments; this effect is probably produced in various manners. Those that are watery, soften, divide, dissolve even certain foods; they aid in this manner their chymification and their passage through the pylorus.

Wine fulfils analogous uses, but only for the substances that it is capable of dissolving; besides, it excites by its contact the mucous membrane of the stomach, and causes a greater secretion of the gastric juice. Alkohol acts much in the same manner as wine, only it is more intense. It is thus that those liquors which are used after meals, are useful in exciting the action of the stomach."—*Magendie's Physiology.*

DIGESTIVE. (*Digestivus;* from *digero,* to dissolve.) A term applied by surgeons to those substances which, when applied to an ulcer or wound, promote suppuration: such are the *ceratum resinæ, unguentum elemi,* warm poultices, fomentations, &c.

Digestive salt. The muriate of potassa.

Digestive salt of Sylvius. The muriate of potassa.

DIGESTI'VUM SAL. See *Potassæ murias.*

DIGITA'LIS. (From *digitus,* a finger; because its flower represents a finger.)

1. The name of a genus of plants in the Linnæan system. Class, *Didynamia;* Order, *Angiospermia.* Fox-glove.

2. The pharmacopœial name of the common fox-glove. See *Digitalis purpurea.*

DIGITALIS PURPUREA. The systematic name of the fox-glove. *Digitalis—calycinis foliolis ovatis acutis, corollis obtusis, labio superiore integro,* of Linnæus. The leaves of this plant have a bitter nauseous taste, but no remarkable smell; they have been long used externally to ulcers and scrophulous tumours with considerable advantage. When properly dried, their colour is a lively green. They ought to be collected when the plant begins to blossom, to be dried quickly before the fire, and preserved unpowdered.

Of all the narcotics, digitalis is that which diminishes most powerfully the actions of the system; and it does so without occasioning any previous excitement. Even in the most moderate dose it diminishes the force and frequency of the pulse, and, in a large dose, reduces it to a great extent, as from 70 beats to 40 or 35 in a minute, occasioning, at the same time, vertigo, indistinct vision, violent and durable sickness, with vomiting. In a still larger quantity, it induces convulsions, coldness of the body, and insensibility; symptoms which have sometimes terminated fatally. As a narcotic, fox-glove has been recommended in epilepsy, insanity, and in some acute inflammatory diseases. Lately it has been very extensively employed in phthisis, and the beneficial effects which it produces in that disease, are probably owing to its narcotic power, by which it reduces the force of the circulation through the lungs and general system. It is administered so as to produce this effect. One grain of the powdered leaves, or ten drops of the saturated tincture, may be given night and morning. This dose is increased one-half every second day, till its action on the system becomes apparent. As soon as the pulse begins to be diminished, the increase of dose must be made with more caution; and, whenever nausea is induced, it ought rather to be reduced, or, if necessary, intermitted for a short time. If the sickness become urgent, it is best relieved by stimulants, particularly large doses of brandy, with aromatics. The tincture has been supposed to be the best form of administering digitalis, when the remedy is designed to act as a narcotic: it is also more manageable in its dose, and more uniform in its strength, than the dried leaves.

Besides its narcotic effects, digitalis acts as one of the most certain diuretics in dropsy, apparently from its power of promoting absorption. It has frequently succeeded where the other diuretics have failed. Dr. Withering has an undoubted claim to this discovery; and the numerous cases of dropsy related by him, and other practitioners of established reputation, afford incontestable evidence of its diuretic powers, and of its practical importance in the cure of those disorders. From Dr. Withering's extensive experience of the use of the digitalis in dropsies, he has been able to judge of its success by the following circumstances;—"It seldom succeeds in men of great natural strength, of tense fibre, of warm skin, of florid complexion, or in those with a tight and cordy pulse. If the belly in ascites be tense, hard, and circumscribed, or the limbs in anasarca solid and resisting, we have but little hope. On the contrary, if the pulse be feeble, or intermitting, the countenance pale, the lips livid, the skin cold, the swollen belly soft and fluctuating, the anasarcous limbs readily pitting under the pressure of the finger, we may expect the diuretic effects to follow in a kindly manner." Of the inferences which he deduces, the fourth is, "that if it (digitalis) fails, there is but little chance of any other medicine succeeding." Although the digitalis is now generally admitted to be a very powerful diuretic, yet it is but justice to acknowledge that this medicine has more frequently failed than could have been reasonably expected from a comparison of the facts stated by Dr. Withering. The dose of the dried leaves in powder is from one to three grains twice a day. But if a liquid medicine be preferred, a drachm of the dried leaves is to be infused for four hours, in half a pint of boiling water, adding to the strained liquor an ounce of any spirituous water. One ounce of this infusion, given twice a day, is a medium dose. It is to be continued in these doses till it either acts upon the kidneys, the stomach, the pulse (which, as has been said, it has a remarkable power of lowering,) or the bowels.

The administration of this remedy requires to be conducted with much caution. Its effects do not immediately appear; and when the doses are too frequent, or too quickly augmented, its action is concentrated so as to produce frequently the most violent symptoms. The general rules are to begin with a small dose, to increase it gradually, till the action is apparent on the kidneys, stomach, intestines, or vascular system; and immediately suspending its exhibition, when its effects on any of these parts take place.

The symptoms arising from too large a dose of digitalis are, extreme sickness, vertigo, indistinct vision, incessant vomiting, and a great reduction of the force of the circulation, terminating sometimes in syncope, or convulsions. They are relieved by frequent and small doses of opium, brandy, aromatics, and strong bitters, and by a blister applied to the region of the stomach.

DIGITATUS. Digitate or fingered. A leaf is called *folium digitatum*, when several leaflets proceed from the summit of a common footstalk, as in *Potentilla verna;* and *reptans.*

DIGITIFORMIS. Finger-like. Applied to the receptacle of the *Arum maculatum*, and *Calla æthiopica.*

Digi'tium. (From *digitus*, a finger.)

1. A contraction of the finger-joint.

2. A whitlow, or other sore upon the finger.

DI'GITUS. (From *digero*, to direct.) A finger. *Digitus manus*, is the finger, properly so called; and *digitus pedis*, the toe.

Digitus manus. A finger. The *fingers* and thumb in each hand consist of fourteen bones, there being three to each *finger*, and two to the thumb; they are a little convex and round towards the back of the hand, but hollow and plain towards the palm, except the last, where the nails are. The order of their disposition is called first, second, and third *phalanx*. The first is longer than the second, and the second longer than the third. What has been said of the fingers applies to the toes also.

Digitus pedis. A toe. See *Digitus Manus.*

DIGLO'SSUM. (From δις, double, and γλωσσα, a tongue: so called because above its leaf there grows a lesser leaf, like two tongues.) 1. The *Laurus alexandrina.*

2. Galen makes mention of a man born with two tongues.

Digno'tio. (From *dignosco*, to distinguish.) See *Diagnosis.*

DIGY'NIA. (From δις, twice, and γυνη, a woman.) The name of an order of several classes of the sexual system of plants, embracing those plants which to the character of the class, whatever it may be, add the circumstance of having two styles.

Dihæ'maton. (From δια, and αιμα, blood.) An antidote in which is the blood of many animals.

Diha'lon. (From δια, and αλς, salt.) A plaster prepared with salt and nitre, adapted to foul ulcers.

Dii'petes. (From Ζευς, διος, Heaven, and ϖιπτω, to fall: *i. e.* falling as rain.) An epithet applied by Hippocrates to semen, when it is discharged like a shower of rain.

DILATA'TIO. (From *dilato*, to enlarge.)

1. Dilatation, or enlargement.

2. The diastole of the heart.

DILA'TOR. (From *dilato*, to enlarge.) The name of some muscles the office of which is to open and enlarge parts.

Dilator alæ nasi. See *Levator labii superioris.*

DILATO'RIUM. (From *dilato*, to enlarge.) A surgical instrument for enlarging any part.

DILL. See *Anethum.*

DILUENT. (*Diluens;* from *diluo*, to wash away.) Those substances which increase the proportion of fluid in the blood. It is evident that this must be done by watery liquors. Water is, indeed, properly speaking, the only diluent. Various additions are made to it, to render it pleasant, and frequently to give it a slightly demulcent quality. But these are not sufficiently important to require to be noticed, or to be classed as medicines.

Diluents are merely secondary remedies. They are given in acute inflammatory diseases, to lessen the stimulant quality of the blood. They are used to promote the action of diuretics in dropsy, and to favour the operation of sweating.

Di'nica. (From δινος, giddiness.) Medicines which relieve a giddiness.

Di'nos. See *Dinus.*

DI'NUS. (From δινεω, to turn round.) *Dinos.* Dizziness. The name of a genus of disease in Good's Nosology. Class, *Neurotica;* Order, *Systatica.* It has only one species. *Dinus vertigo.* Vertigo, or giddiness.

Dio'cres. The name of a lozenge.

Di'odos. (From δια, and οδος, the way through.) Evacuation by stool.

DIŒ'CIA. (From δις, double, and οικια, a house.) The name of a class of plants in the sexual system of Linnæus, containing such as have barren, or male, flowers on one individual, and fertile, or female, ones no another of the same species.

Diœna'nthes. (From δια, and οιναvθη, the flower of the vine.) A remedy said to be good for cholera, in which was the flower of the vine-tree.

DIO'GMUS. (From διωκω, to persecute.) A distressing palpitation of the heart.

DIOI'CUS. (From δις, double, and οικια, a house.) Dioecious. Plants and flowers are so called when the barren and fertile flowers grow from two separate roots.

DIONIS, Peter, was born about the middle of the 17th century, and educated to the practice of surgery. He was appointed to read the lectures in anatomy, &c. in the royal gardens at Paris, instituted by Lewis XIV., and after this, surgeon to the queen, and other branches of the royal family, which offices he held, with great credit, to his death, in 1718. His first publication gave an account of a woman who died in the sixth month of pregnancy, of what he considered to be a ruptured uterus; but as he states that there were two uteri, it is suspected that the ruptured part was one of the Fallopian tubes much enlarged. He afterwards gave a useful epitome of anatomy, which was very favourably received, passed through several editions, and was even translated into the Tartar language, by order of the Emperor of China. His next work, a course of surgical operations, obtained still more celebrity, which it even now in some degree retains, especially as commented upon by Heister. Besides these, a dissertation on sudden death, and a treatise on midwifery, were published by this author.

Dionysi'cus. (From Διονυσος, Bacchus, who was of old represented as having horns.) Certain bony excrescences, near the temples were called dionysisci.

Dionysony'mphas. (From Διονυςος, Bacchus, and νυμφα, a nymph.) An herb which, if bruised, smells of wine, and yet resists drunkenness.

Diopo'rum. (From δια, and οπωρα, autumnal fruits.) A medicine composed of ripe fruits for quincy.

DIOPSIDE. A subspecies of oblique edged augite, found near Piedmont.

DIOPTASE. Emerald copper ore.

Dio'ptra. (From διοπτομαι, to see through.) *Dioptron.* 1. Speculum ani, oris, or uteri.

2. The lapis specularis.

DIO'PTRICS. (*Dioptricus*; from διοπτομαι, to see through.) The doctrine of the refraction of light.

Dioptri'smus. (From διοπτομαι, to see through.) Dilatation of any natural passage.

Dio'robum. (From δια, and οροβος, a vetch.) A medicine, in the composition of which there are vetches.

Diorrho'sis. (From δια, and οῤῥος, the serum.) *Diorosis.* 1. A dissolved state of the blood.

3. A conversion of the humours into serum and water.

Diorthro'sis. (From διορθροω, to direct.) The reduction of a fracture.

DIOSCO'REA. (Named in honour of Dioscorides.) The name of a genus of plants in the Linnæan system. Class, *Diœcia*; Order, *Hexandria.*

Dioscorea alata. The name of the plant which affords the esculent root, called the yam. It is obtained, however, from three species; the *alata, bulbifera,* and *sativa.* They grow spontaneously in both Indies, and their roots are promiscuously eaten as the potatoe is with us. There is great variety in the colour, size, and shape of yams; some are generally blue or brown, round or oblong, and weigh from one pound to two. They are esteemed when dressed as being nutritious and easy of digestion, and are preferred to wheaten bread. Their taste is somewhat like the potatoe, but more luscious. The negroes, whose common food is yams, boil and mash them. They are also ground and made into bread and puddings.

When they are to be kept for some time, they are exposed upon the ground to the sun, as we do onions, and when sufficiently withered, they are put into dry sand in casks, and placed in a dry garret, where they remain often for many seasons without losing any of their primitive goodness.

Dioscorea bulbifera. See *Dioscorea alata.*

Dioscorea sativa. See *Dioscorea alata.*

DIOSCOR'IDES, Pedacius, or Pedanius, a celebrated Greek physician and botanist of Anazarba, in Cilicia, now Caramania, who is supposed to have lived in the time of Nero. He is said to have been originally a soldier, but soon became eminent as a physician, and travelled much to improve his knowledge. He paid particular attention to the materia medica, and especially to botany, as subservient to medicine. He profited much by the writings of Theophrastus, who appears to have been a more philosophical botanist. Dioscorides has left a treatise on the materia medica, in five books, chiefly considering plants; also two books on the composition and application of medicines, an essay on antidotes, and another on venomous animals. His works have been often printed in modern times, and commented upon, especially by Matthiolus. He notices about 600 plants, but his descriptions are often so slight and superficial, as to leave their identity a matter of conjecture; which is perhaps of no very great medical importance; though their virtues being generally handed down from the Greeks, it might be useful to ascertain which particular plants they meant.

Dioscu'ri. (*i. e.* Διος, Κουροι, the sons of Jupiter, or Castor and Pollux.) The parotid glands were so named from their twin-like equality in shape and position.

Diospy'ros lotus. The Indian date plum. The fruit when ripe, has an agreeable taste, and is very nutritious.

Dioxelæ'um. (From δια, οξυς, acid, and ελαιον, oil.) A medicine composed of oil and vinegar.

Dio'xos. (From δια, and οξυς, acid.) A collyrium composed chiefly of vinegar.

DIPHYLLUS. (From δις, double, and φυλλον, a leaf.) Diphyllous, or two-leaved. Applied to the perianthium of flowers, when there are two calyces; as in *Papaver rhœas.*

Diplasia'smus. (From διπλοω, to double.) The re-exacerbation of a disease.

DI'PLOE. (From διπλοω, to double.) The spongy substance between the two tables of the skull.

DIPLO'PIA. (From διπλοος, double, and οπτομαι, to see.) *Visus duplicatus.* A disease of the eye, in which the person sees an object double or triple. Dr. Cullen makes it a variety of the second species of pseudoblepsis, which he calls mutans, in which objects appear changed from what they really are; and the disease varies according to the variety of the remote causes.

Di'pnoos. (From δις, twice, and πνεω, to breathe.) A wound which is perforated quite through, and admits the air at both ends.

Dipple's animal oil. See *Animal oil.*

DI'PSACUS. (From διψα, thirst: so called from the concave situation of its leaves, which hold water, by which the thirst of the traveller may be relieved.) *Dipsacum.*

1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia.* The teasel.

2. A diabetes, from the continual thirst attending it.

DIPSOSIS. (From διψα, thirst.) The name of a genus of diseases in Good's Nosology, known by the desire for drinking being excessive or impaired. It has two species, *Dipsosis avens*, and *Dipsosis expers.*

DIPYRE. Schmelstein. A mineral found in white or reddish steatite in the Western Pyrenees, composed of silica, alumina, and lime.

Dipyre'num. (From δις, twice, and πυρην, a berry.) 1. A berry, or kernel.

2. A probe with two buttons.

Dipyri'tes. (From δις, twice, and πυρ, fire.) *Dipyros.* An epithet given by Hippocrates to bread twice baked, and which he recommended in dropsies.

DIRE'CTOR. (From *dirigo*, to direct.)

1. A hollow instrument for guiding an incisor-knife.

2. The name of a muscle.

Director penis. (From *dirigo*, to direct.) The same as erector penis.

Diri'nga. A name, in the isle of Java, for the *Calamus aromaticus.* See *Acorus calamus.*

Disce'ssus. (From *discedo*, to depart.) The separation of any two bodies, before united, by chemical operation.

DISCIFO'RMIS. (From *discus*, a quoit, and *forma*, likeness.) Resembling a disk, or quoit, in shape. It is applied to the knee-pan.

DISCOI'DES. (From δισπος, a quoit, and ειδος, resemblance.) Resembling a disk, or quoit, in shape. It is applied to the crystalline humour of the eye.

Discri'men. 1. A small roller.

2. The diaphragm.

DISCUS. (From δισκος, a quoit and disk, and from its flat and round appearance like the circumference of the sun.) The disk, or central part of a leaf, and of a compound flower. In the common daisy, the white leaflets of the flower surround the disk.

The disk of a leaf is the whole flat surface within the margin.

DISCU′TIENT. (*Discutiens; from discutio*, to shake in pieces.) *Discusorius; Diachyticus.* A term in surgery, applied to those substances which possess a power of repelling or resolving tumours.

DISEASE. *Morbus.* Any alteration from a perfect state of health. A disease is variously termed: when it pervades the whole system, as fever does, it is called a *general disease*, to distinguish it from inflammation of the eye, or any other viscus, which is a *partial* or *local* one. When it does not depend on another disease, it is termed *idiopathic*, which may be either general or partial, to distinguish it from a *symptomatic* one, which depends upon another disease. See also *Endemic, Epidemic, Sporadic*, &c.

DISK. See *Discus.*

DISLOCA′TION. (*Dislocatio;* from *disloco*, to put out of place.) Luxation. The secession of a bone of a moveable articulation from its natural cavity.

DISPE′NSARY. (*Dispensarium;* from *dispendo*, to distribute.) 1. The shop or place in which medicines are prepared.

2. The name of an institution, in which the poor are supplied with medicines and advice.

DISPE′NSATORY. (*Dispensatorium;* from *dispendo*, to distitabute.) *Antidotarium.* A book which treats of the composition of medicines.

DISSE′CTION. (*Dissectio;* from *disseco*, to cut asunder.) The cutting to pieces of any part of an animal, or vegetable, for the purpose of examining its structure. See *Anatomy.*

DISSECTUS. Cut. A term used by botanists synonymously with *incised* and *laciniated*, to leaves which are cut, as it were, into numerous irregular portions. See *Leaf.*

DISSEPIMENTUM. (From *dissepio*, to separate.) A partition. Applied by botanists to partitions which separate the cells of a capsule. See *Capsula.*

DISSE′PTUM. (From *dissepio*, to inclose round.) The diaphragm, or membrane, which divides the cavity of the thorax from the abdomen.

DISSOLVE′NTIA. (From *dissolvo*, to loosen.) 1. Medicines which loosen and dissolve morbid concretions in the body.

2. In chemistry, it means menstrua.

DISSOLU′TUS. (From *dissolvo*, to loosen.) Loose, morbus dissolutus. An epithet applied to dysentery.

DISTANS. Distant. Applied to petals from their direction; as in *Cucubalus bacciferus.*

DISTE′NTIO. (From *distendo*, to stretch out.) 1. Distention, or dilatation.

2. A convulsion.

DISTHENE. See *Cyanite.*

DISTI′CHIA. See *Distichiasis.*

DISTICHI′ASIS. (From διστιχια, from δις, double, and ςιχος, a row.) *Districhiasis; Distichia.* A disease of the eye-lash, in which there is a double row of hairs, the one row growing outwards, the other inwards towards the eye.

DISTICHUS. Two-ranked. Applied to stems, leaves, &c. when they spread in two horizontal directions; as the branches of the *Pinus picea*, or silver fur, and the leaves of the *Taxus baccata*, or yew.

DISTILLA′TION. (*Distillatio;* from *distillo*, to drop little by little.) *Alsacta; Catastagmos.* A chemical process, very similar to evaporation, instituted to separate the volatile from the fixed principles, by means of heat. Distillatory vessels are either alembics or retorts; the former consist of an inferior vessel called a cucurbit designed to contain the matter to be examined, and having an upper part fixed to it, called the capital, or head. In this last, the vapours are condensed by the contact of the surrounding air, or, in other cases, by the assistance of cold water surrounding the head, and contained in a vessel called the refrigeratory. From the lower part of the capital proceeds a tube, called the nose, beak, or spout, through which the vapours, after condensation, are, by a proper figure of the capital, made to flow into a vessel called the receiver, which is usually spherical. These receivers have different names, according to their figure, being called mattrasses, balloons, &c. Retorts are a kind of bottle of glass, pottery, or metal, the bottom being spherical, and the upper part gradually diminishing into a neck, which is turned on one side.

Distilled vinegar. See *Acetum.*

DISTO′RTION. (*Distortio;* from *distorqueo*, to wrest aside.) A term applied to the eyes, when a person seems to turn them from the object he would look at, and is then called squinting, or strabismus. It also signifies the bending of a bone preternaturally to one side; as distortion of the spine, or vertibræ.

DISTO′RTOR. (From *distorqueo*, to wrest aside.) A muscle, the office of which is to draw the mouth awry.

DISTORTOR ORIS. See *Zygomaticus minor.*

DISTRICHI′ASIS. See *Distichiasis.*

DI′STRIX. (From δις, double, and θριξ, the hair.) A disease of the hair, when it splits and divides at the end.

DITTANDER. See *Lepidium sativum.*

DITTANY. See *Dictamnus.*

Dittany, bastard. See *Dictamnus albus.*

Dittany of Crete. See *Origanum dictamnus.*

Dittany, white. See *Dictamnus albus.*

DIURE′SIS. (From δια, through, and ουρεω, to make water.) An increased secretion of urine. It is also applied to a diabetes.

DIURETIC. (*Diureticus.* Διουρητικος; from διουρησις, a discharge of urine.) That which, when taken internally, augments the flow of urine from the kidneys. It is obvious that such an effect will be produced by any substance capable of stimulating the secreting vessels of the kidneys. All the saline diuretics seem to act in this manner. They are received into the circulation; and passing off with the urine, stimulate the vessels, and increase the quantity secreted.

There are other diuretics, the effect of which appears not to arise from direct application, but from an action excited in the stomach, and propagated by nervous communication to the secreting urinary vessels.

The diuretic operation of squill, and other vegetables, appears to be of this kind.

There is still, perhaps, another mode in which certain substances produce a diuretic effect; that is by promoting absorption. When a large quantity of watery fluid is introduced into the circulating mass, it stimulates the secreting vessels of the kidneys, and is carried off by urine. If, therefore, absorption be promoted, and if a portion of serous fluid, perhaps previously effused, be taken up, the quantity of fluid secreted by the kidneys will be increased. In this way digitalis seems to act: its diuretic effect, it has been said, is greater when exhibited in dropsy than it is in health.

On the same principle (the effect arising from stimulating the absorbent system,) may probably be explained the utility of mercury in promoting the action of several diuretics.

The action of these remedies is promoted by drinking freely of mild diluents. It is also influenced by the state of the surface of the body. If external heat be applied, diuresis is frequently prevented, and diaphoresis produced. Hence the doses of them should be given in the course of the day, and the patient, if possible, be kept out of bed.

The direct effects of diuretics are sufficiently evident. They discharge the watery part of the blood; and, by that discharge, they indirectly promote absorption over the whole system.

Dropsy is the disease in which they are principally employed; and when they can be brought to act, the disease is removed with less injury to the patient than it can be by exciting any other evacuation. Their success is very precarious, the most powerful often failing: and, as the disease is so frequently connected with organic affection, even the removal of the effused fluid, when it takes place, only palliates without effecting a cure.

Diuretics have been likewise occasionally used in calculous affections, in gonorrhœa, and with a view of diminishing plethora, or checking profuse perspiration.

Murray, in his Elements of Materia Medica, classes the super-tartrate of potassa, or cream of tartar, and nitrate of potassa, or nitre, the muriate of ammonia, or crude sal-ammoniac, potassa, and the acetate of potassa, or kali acetatum, among the *saline* diuretics; and selects the following from the *vegetable* kingdom:—scilla maritima, digitalis purpurea, nicotiana tabacum, solanum dulcamara, lactuca virosa, colchicum autumnale, gratiola officinalis, spartium scoparium, juniperus communis, copaifera officinalis, pinus balsamea, and pinus larix; and the lytta vesicatoria from the *animal* kingdom.

In speaking of particular diuretics, Dr. Cullen says, the diuretic vegetables mentioned by writers are of very little power, and are employed with very little success. Of the umbellatæ, the medicinal power resides especially in their seeds; but he never found any of them very efficacious. The semen dauci sylvestris has been commended as a diuretic; but its powers as such are not very remarkable. In like manner, some of the *plantæ stellatæ* have been commended as diuretics; but none of them deserve our notice, except the *rubia tinctorium*, the root of which passes so much by the kidneys as to give its colour to the urine. Hence it may fairly be supposed to stimulate the secretories; but Dr. Cullen found its diuretic powers did not always appear and never to any considerable degree; and as, in brute animals, it has always appeared hurtful to the system, he does not think it fit to be employed to any extent in human diseases. The bardana, lithospermum, ononis, asparagus, enula campana, are all substances which seem to pass, in some measure, by the kidneys; but their diuretic powers are hardly worth notice.

The principal articles included by Dr. Cullen, in his catalogue of diuretics, are dulcamara, digitalis, scilla; some of the alliaceæ and siliquosæ; the balsams and resins; cantharides, and the diuretic salts.

Divapora′tio. Evaporation.

DIVARICATION. The crossing of any two things: thus when the muscular or tendinous fibres intersect each other at different angles, they are said to divaricate.

Divellent affinity. See *Affinity quiescent.*

Diverso′rium. (From *diversor*, to resort to.) The receptaculum chyli.

DIVERTI′CULUM. A mal-formation or diseased appearance of a part, in which a portion goes out of the regular course; and thereby forms a diverticulum, or deviation from the usual course. It is generally applied to the alimentary canal.

Diverticulum nuckii. The opening through which the round ligaments of the uterus pass. Nuck asserted that it remained open a long time after birth; to these openings he gave the name of *diverticula.*

DIVI′NUS. A pompous epithet of many compositions, from their supposed excellence.

Divu′lsio. (From *divello*, to pull asunder.) Urine with uneven sediment.

DOCIMASTIC. *Ars docimastica.* The art of examining fossils, in order to discover what metals, &c. they contain.

DOCK. See *Rumex.*

Dock-cresses. See *Lapsana.*

Dock, sour. See *Rumex acetosa.*

Dock, water. See *Rumex hydrolapathum.*

DODDER. See *Cuscuta epithymum.*

Dodecada′ctylus. (From *δωδεκα*, twelve, and *δακτυλος*, a finger; so named because its length is about the breadth of twelve fingers.) The duodenum, an intestine so called. It must be observed, that at the time this name was given, anatomy consisted in the dissection of brutes; and the length was therefore probably adjudged from the gut of some animal, and not of man.

DODECA′NDRIA. (From *δωδεκα*, twelve, and *ανηρ*, a man.) The name of a class of plants in the sexual system, embracing those with hermaphrodite flowers, and twelve stamina.

Dodecapha′rmacum. (From *δωδεκα*, twelve, and *φαρμακον*, a medicine.) An ointment consisting of twelve ingredients, for which reason it was called the ointment of the twelve apostles.

Dodeca′theon. (From *δωδεκα*, twelve, and *τιθημι*, to put.) An antidote consisting of twelve simples.

DODONÆUS, Rembertus, (or Dodoens,) was born at Mechlin in 1517. He became physician to two succeeding emperors, and in 1582 was appointed professor of physic in the newly-founded University of Leyden, the duties of which he performed with credit till his death, three years after. His fame at present chiefly rests on his botanical publications, particularly his "Pemptades," or 30 books of the history of plants. The "Frugum Historia," "Herbarium Belgicum," &c. are of much inferior merit.

DOG. See *Canis.*

Dog's-bane, Syrian. See *Asclepias syriaca.*

Dog's-grass. See *Triticum repens.*

Dog's-mercury. See *Mercurialis perennis.*

Dog-rose. See *Rosa canina.*

Dog-stones. See *Orchis mascula.*

DO′GMA. (From *δοκεω*, to be of opinion.) A dogma, or opinion founded on reason and experience.

DOLERITE. When volcanic masses are composed of grains distinct from each other, and contain besides felspar, much pyroxene, black oxide of iron, ampibole, &c. they are called by the French geologist, *dolerite.*

DO′LICHOS. (From *δολιχος*, long: so called from its long shape.) 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria.*

2. The pharmacopœial name of the cowhage. See *Dolichos pruriens.*

Dolichos pruriens. The systematic name of the cowhage. *Dolichos; Dolichos—volubilis, leguminibus racemosis, valvulis subcarinatis hirtis, pedunculis ternis,* of Linnæus. The pods of this plant are covered with sharp hairs, which are the parts employed medicinally in form of electuary, as anthelmintics. The manner in which these hairy spicula act, seems to be purely mechanical: for neither the tincture, nor the decoction, possess the least anthelmintic power.

Dolichos soja. The plant which affords the soy. It is much cultivated in Japan, where it is called *daidsu:* and where the pods supply their kitchens with various productions; but the two principal are, a sort of butter, termed *miso,* and a pickle called *sooju.*

DOLABRIFORMIS. (From *dolabella,* a hatchet, and *forma,* resemblance.) Hatchet-shaped. A term applied to a leaf, which is compressed with a very prominent dilated keel, and a cylindrical base; as in *Misembryanthemum dolabriforme.*

DOLOMITE. A calcareo-magnesian carbonate.

DO'LOR. (*Dolor, oris.* f.) Pain.

Dolor faciei. See *Tic douloureux.*

DORO'NICUM. (From *dorongi,* Arab.) Leopard's bane. See *Arnica montana.*

Doronicum germanicum. See *Arnica montana.*

Doronicum romanum. The pharmacopœial name of the Roman leopard's bane. See *Doronicum pardalianches.*

Doronicum pardalianches. The systematic name of the Roman leopard's bane. *Doronicum romanum; Doronicum—foliis cordatis, obtusis, denticulatis; radicalibus petiolatis; caulinis amplexicaulibus,* of Linnæus. The root of this plant, if given in a full dose, possesses poisonous properties; but instances are related of its efficacy in epileptical and other nervous diseases.

DO'RSAL. (*Dorsalis;* from *dorsum,* the back.) Belonging to the back.

Dorsalis nervus. The nerve which passes out from the vertebræ of the back.

DORSTE'NIA. (Named in honour of Dr. Dorsten.) The name of a genus of plants in the Linnæan system. Class, *Tetrandria;* Order, *Monogynia.*

Dorstenia braziliensis. The root of this plant is used by the natives of Brazil, internally and externally. They call it *Caa-apia.* When chewed, it has the same effects as ipecacuanha. The wounds from poisoned darts, are said to be cured with the juice of the root, which they pour into the wound.

Dorstenia contrayerva. The systematic name of the plant which affords the contrayerva root; *Contrayerva; Drakena; Cyperus longus, odorus, peruanus; Bezoardica radix.* The contrayerva root was first brought into Europe about the year 1581, by Sir Francis Drake, whence its name Drakena. It is the root of a small plant found in Peru, and other parts of the Spanish West Indies. Dr. Houston observes, that the roots of different species of dorstenia are promiscuously gathered and exported for those of the contrayerva, and, as all the species bear a great resemblance to each other, they are generally used for medical purposes in this country. The tuberous parts of these roots are the strongest, and should be chosen for use. They have an agreeable aromatic smell; a rough bitter, penetrating taste; and, when chewed, they give out a sweetish kind of acrimony.

It is diaphoretic and antiseptic; and was formerly used in low nervous fevers, and those of the malignant kind; but its use is superseded by the cinchona.

Dr. Cullen observes, that this and serpentaria are powerful stimulants; and both have been employed in fevers in which debility prevailed. However, he thinks, wine may always supersede the stimulant powers of these medicines; and that debility is better remedied by the tonic and antiseptic powers of cold and Peruvian bark, than by any stimulants.

By the assistance of heat, both spirit and water extract all its virtues; but they carry little or nothing in distillation; extracts made by inspissating the decoction, retain all the virtues of the root.

The London College forms the compound powder of contrayerva, by combining five ounces of contrayerva root with a pound and a half of prepared shells. This powder was formerly made up in balls, and called *lapis contrayervæ,* employed in the decline of ardent fevers, and through the whole course of low and nervous ones. The radix serpentariæ virginiensis, in all cases, may be substituted for the contrayerva.

Drostenia drakena. The systematic name for one sort of the contrayerva.

Dorstenia houstonii. See *Dorstenia contrayerva.*

Do'thien. A name for the furunculus.

DOUGLAS, James, M.D. was born in Scotland in 1675. After completing his education, he came to London, and applied himself diligently to the study of anatomy and surgery, which he both taught and practised several years with success. Haller has spoken very highly of his preparations, to show the motion of the joints, and the structure of the bones. He patronised the celebrated William Hunter; who assisted him shortly before his death in 1742. He was reader of Anatomy to the Company of Surgeons, and a Fellow of the Royal Society, to which he made several communications. He published, in 1707, a more correct description of the muscles than had before appeared; eight years after, a tolerable account of preceding anatomical writers; in 1726, a History of the lateral Operation for the Stone; and in 1730, a very accurate Description of the Peritonæum, &c.

DOUGLAS, John, brother of the preceding, was surgeon to the Westminster Infirmary, and author of several controversial pieces. In one of them, called "Remarks on a late pompous Work," he censures, with no small degree of severity, Cheselden's Anatomy of the Bones; in another, he criticises, with equal asperity, the works of Chamberlen and Chapman; and in a third, he decries the new forceps of Dr. Smellie. He also wrote a work on the high operation for the stone, which he practised; a Dissertation on the Venereal Disease; and an Account of the Efficacy of Bark in stopping Gangrene.

DOVE'S FOOT. See *Geranium rotundifolium.*

Dover's powder. See *Pulvis ipecacuanhæ compositus.*

Down of seed. See *Pappus.*

DRA'BA. (From δρασσω, to seize; so called from its sudden effect upon the nose of those who eat it.) The name of a genus of plants in the Linnæan system. Class, *Tetradynamia;* Order, *Siliculosa.*

Draba verna. A common plant on most

walls. The seed is hot and stimulating, and might be used for pepper.

DRA'CO. (*Draco, onis.* m. Δρακων, the dragon.) The dragon.

Draco mitigatus. The submuriate of mercury.

Draco sylvestris. See *Achillea Ptarmica.*

DRACOCE'PHALUM. (From δρακων, a dragon, and κεφαλη, a head.) The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Gymnospermia.*

Dracocephalum canariense. The systematic name of the balm of Gilead. Turkey-balsam; Canary balsam; Balsam of Gilead. *Moldavica; Melissa Turcica. Dracocephalum moldavica—floribus verticellatis, bracteis lanceolatis, serraturis capillaceis* of Linnæus. This plant affords a fragrant essential oil, by distillation, known in Germany by the name of *oleum syriæ.* The whole herb abounds with an aromatic smell and an agreeable taste, joined with an aromatic flavour; it is recommended to give tone to the stomach and nervous system.

Draconis sanguis. Dragon's blood. See *Calamus rotang.*

Dracontia. The dracontra of the Greeks, according to Pliny, was the Guinea worm, or *dracunculus.* See *Medinensis vena.*

Draco'ntium. (From δρακων, a dragon; so called because its roots resemble a dragon's tail.) See *Arum dracunculus.*

DRACU'NCULUS. (From δρακων, a serpent.) *Gordius medinensis; Vermis medinensis; Vena medinensis; Vermiculus capillaris.* The Guinea worm. This animalcule is common in both Indies, in most parts of Africa, occasionally at Genoa, and other hot countries. It resembles the common worm, but is much larger; is commonly found in the legs, but sometimes in the muscular part of the arms. It principally affects children, and its generation is not unlike that of the broad worms of the belly. While it moves under the skin, it creates no trouble; but, in length of time, the place near the dracunculus suppurates, and the animal puts forth its head. If it be drawn, it excites considerable uneasiness, especially if drawn so forcibly as to break it; for the part left within creates intolerable pain. These worms are of different lengths. In the Edin. Med. Essays, mention is made of one that was three yards and a half in length.

Dracunculus pratensis. See *Achillea ptarmica.*

Dragaca'ntha. See *Astragalus.*

Dragant gum. See *Astragalus.*

DRAGON. See *Draco.*

Dragon's blood. See *Calamus rotang.*

Dragon's wort. See *Arum dracunculus.*

DRAKE, James, M.D. Fellow of the College of Physicians, and of the Royal Society, published, in 1707, "A new System of Anatomy;" which, though taken principally from Cowper, being on a reduced plan, and more within the reach of students, was pretty favourably received. In the third edition, it was styled "Anthropologia Nova." In abscesses of the antrum maxillare, he advised drawing one of the molar teeth, to let out the matter. The description of the internal nostrils, and of the cavities entering them, is new; as are also the plates of the abdominal viscera.

Drake'na. See *Dorstenia contrayerva.*

DRA'STIC. (*Drasticus.* Δραστικος, active, brisk; from δραω, to effect.) A term generally applied to those medicines which are very violent in their action; thus, drastic purges, emetics, &c.

Drawing slate. See *Chalk, black.*

DRELINCOURT, Charles, was born at Paris in 1633; and after studying some years at Saumur, he went to graduate at Montpelier. He soon after attended the celebrated Turenne in his campaigns, and was by him made physician to the army. He was also appointed one of the physicians to Lewis XIV. But in 1688 he was chosen to succeed Vander Linden, as professor of medicine at Leyden; and two years after he was advanced to the chair of anatomy. He was also made physician to William, then Prince of Orange, and his consort; and on their accession to the throne of England, he spoke the congratulatory oration to them, as rector of the university. He continued in his professorship, giving general satisfaction to the period of his death in 1697. He was a voluminous and learned, but hardly an original writer; yet his works were very much read at the time. In one of his orations, he exculpates medical men from the charge of impiety, observing that the contemplation of the works of God tends to blind them more to religion. In his "Apologia Medica," he refutes the notion, that physicians were excluded from Rome for six hundred years. He strenuously opposed the introduction of chemical preparations into medicine, which was then very prevalent. His son, *Charles,* succeeded him in practice, but has left no publication, except his thesis "De Lienosis."

Dro'ma. The name of a plaster described by Myrepsus.

Dropaci'smus. (From δρεπω, to remove.) *Dropax.* A stimulant plaster of pitch, wax, &c. to take off hair.

Dro'pax. See *Dropacismus.*

DRO'PSY. *Hydrops.* A collection of a serous fluid in the cellular membrane; in the viscera and the circumscribed cavities of the body. See *Hydrops, Ascites, Anasarca, Hydrocephalus, Hydrothorax, Hydrocele.*

Dropsy of the belly. See *Ascites.*

Dropsy of the brain. See *Hydrocephalus.*

Dropsy of the chest. See *Hydrothorax.*

Dropsy of the ovary. See *Ascites.*

Dropsy of the skin. See *Anasarca.*

Dropsy of the testicle. See *Hydrocele.*

DROPWORT. See *Œnanthe,* and *Spiræa.*

Dropwort, hemlock. See *Œnanthe.*

Dropwort, water. See *Œnanthe.*

DRO'SERA. (From δροσερα, dewy; which is from δροσος, dew; drops hanging on the leaves like dew.) The name of a genus of plants. Class, *Pentandria*; Order, *Hexagynia.* Sundew.

Drosera rotundifolia. The systematic name of the sun-dew. *Ros solis; Rorella.* Sundew. *Drosera rotundifolia—scapis radicatis; foliis orbiculatis* of Linnæus. This elegant little plant is said to be so acrid as to ulcerate the skin, and remove warts and corns; and to excite a fatal coughing and delirium in sheep who eat it. It is seldom given medicinally in this country but by the lower orders, who esteem a decoction of it as serviceable in asthmas and coughs.

Drosobo'tanum. (From δροσος, dew, and βοτανη, an herb: so called from its being covered with an aromatic dew.) The herb betony. See *Betonica.*

Drosso'meli. (From δροσος, dew, and μελι, honey.) Honey-dew. Manna.

DRUPA. (*Drupæ,* unripe olives.) A stone fruit formed of a fleshy or coriaceous seed-vessel, enclosing a nut.

It is distinguished into,

1. *Drupa succosa,* when of a succulent fleshy consistence; as the cherry, plum, peach, and nectarine.

2. *D. fibrosa*, the nut being fibrose; as in *Cocus nucifera.*

3. *D. exsicca*, dry and subcoriaceous; as the almond and horse-chesnut.

4. *D. dehiscens*, opening; as in *Juglans regia*, and *Myristica moschata.*

From the number of nuts it contains, the *drupa* is said to be *monosperma*, when there is but one, as in the olive and pistachia; and *disperma* when there are two, as in *Styrax.*

DRUPACEUS. Drupaceous; resembling a drupe, or stone fruit. Applied to the pod of *Erucago* and *Bunias.*

DUCT. See *Ductus.*

Duct, biliary. See *Biliary duct.*

DUCTI'LITY. *Ductilitas.* A property by which bodies are elongated by repeated or continued pressure. It is peculiar to metals. Most authors confound the words malleability, laminability, and ductility, together, and use them in a loose indiscriminate way; but they are very different. Malleability is the property of a body which enlarges one or two of its three dimensions by a blow or pressure very suddenly applied. Laminability belongs to bodies extensible in dimension by a gradually applied pressure; and ductility is properly to be attributed to such bodies as can be rendered longer and thinner by drawing them through a hole of less area than the transverse section of the body so drawn.

DU'CTUS. A canal or duct.

DUCTUS ARTERIOSUS. A great artery-like canal found only in the fœtus, and very young children, between the pulmonary artery and the aorta. In adults it is closed up.

DUCTUS AURIS PALATINUS. The Eustachian tube.

DUCTUS BILIARIS. See *Choledochus ductus.*

DUCTUS COMMUNIS CHOLEDOCHUS. See *Choledochus ductus.*

DUCTUS CYSTICUS. The trunk of the biliary ducts in the liver which carries the bile from them into the gall-bladder.

DUCTUS HEPATICUS. See *Hepatic duct.*

DUCTUS LACHRYMALIS. See *Lachrymal ducts.*

DUCTUS LACTIFERUS. *Ductus galactophorus.* The excretory ducts of the glandular substance composing the female breast. The milk passes along these ducts to the nipple.

DUCTUS AD NASUM. See *Canalis nasalis.*

DUCTUS PANCREATICUS. The pancreatic duct. It is white and small, and arises from the sharp extremity of the pancreas, runs through the middle of the gland towards the duodenum, into which it pours its contents by an opening common to it and the *ductus communis choledochus.*

DUCTUS SALIVALES. The excretory ducts of the salivary glands, which convey the saliva into the mouth.

DUCTUS STENONIS. The Stenonian duct, which was so called after its discoverer, *Steno.* It arises from all the small excretory ducts of the parotid gland, and passes transversely over the masseter muscle, penetrates the buccinator, and opens into the mouth.

DUCTUS THORACICUS. See *Thoracic duct.*

DUCTUS VENOSUS. When the vena cava passes the liver in the fœtus, it sends off the ductus venosus, which communicates with the sinus of the vena portæ; but, in adults, it becomes a flat ligament.

DUCTUS WARTHONIANUS. The excretory duct of the maxillary glands; so named after its discoverer.

DULCA'CIDUM. (From *dulcis*, sweet, and *acidus*, sour.) A medicine composed of a sweet and sour ingredient.

DULCAMA'RA. (From *dulcis*, sweet, and *amarus*, bitter.) Bitter sweet. See *Solanum dulcamara.*

Dumbness. See *Aphonia* and *Paracusis.*

DUMOSUS. (From *dumus*, a bush.) Bushy.

DUMOSÆ. The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of shrubby plants, which are thick set with irregular branches, and bushy.

DUNCAN, DANIEL, was born at Montauban, in Languedoc, in 1649, son of a professor of physic in that city, but of a family originally Scotch. Having lost both his parents in early infancy, he was taken under the protection of his maternal uncle, and at a proper age sent to study medicine at Montpellier, where he took his degree. He afterwards resided seven years at Paris, where he published his first work, upon the principle of motion in animal bodies. He then visited London, partly to arrange some family affairs, partly to obtain information concerning the plague; and intended to have settled there, but after two years he was summoned to attend his patron, the great Colbert. He soon after made public two works, in which he attempted to explain the Annual Functions on Chemical and Mechanical Principles. On the death of Colbert, he resided for some years in his native city; but the persecution of the Protestants in 1690 drove him to Switzerland, and he was appointed Professor of Anatomy and Chemistry at Berne, where he got into considerable practice. In 1699 he was sent for to attend the Princess of Hesse-Cassel, who had symptoms of threatening consumption, induced by the excessive use of tea, and other hot liquors; which led him to write a Treatise against that practice, published subsequently by the persuasion of his friend, Boerhaave. He remained there three years, affording meanwhile much relief to the French refugees; and the fame of his liberality procured his invitation to the court of Berlin: but a regard to his health and to economy soon obliged him to remove to the Hague. In 1714 he accomplished his favourite object of settling in London, and when he reached his 70th year, put in practice his previous resolution of giving his professional services only gratuitously: in which he steadily persevered during the remaining sixteen years of his life, though, in 1721, he lost the third part of his property by the South-sea scheme.

DUNG. See *Fæx.*

Dung, devil's. See *Ferula assafœtida.*

DUO. (Δυω, two.) Some compositions consisting of two ingredients, are distinguished by this term; as pilulæ ex duobus.

DUODE'NUM. (From *duodenus*, consisting of twelve; so called because it was supposed not to exceed the breadth of twelve fingers: but as the ancients dissected only animals, this does not hold good in the human subject.) The first portion of the small intestines. See *Intestines.*

DUPLEX. (From *duo*, two, and *plico*, to fold.) Double or two-fold. In botany applied to leaves, petals, perianths, &c. The *perianthum duplex* is seen in *Malva althæa* and *Hibiscus.*

DUPLICA'NA. (From *duplex*, double.) A name of the double tertian fever.

DUPLICATUS. (From *duplex*, double.) This term is applied to a flower which has two series or rows of petals.

DU'RA MATER. (From *durus*, hard, and *mater*, a mother: called *dura*, from its comparative hardness with the *pia mater;* and *mater*, from its being supposed to be the source of all the other membranes. Other parts have received the trivial name of dura, from their comparative hardness; as portio dura, a branch of the seventh pair of nerves.) *Dura meninx; Dermatodes.* A thick and somewhat opaque and insensible membrane, formed of two layers, that surrounds and defends the brain, and adheres strongly to the internal surface of the cranium. It has three considerable processes, the falciform, the tentorium, and the septum cerebelli; and several sinuses, of which the longitudinal, lateral, and inferior longitudinal, are the principal. Upon the external surface of the dura mater, there are little holes, from which emerge fleshy-coloured papillæ, and which, upon examining the skull-cap, will be found to have corresponding foveæ. These are the external glandulæ Pacchioni. They are in number from ten to fifteen on each side, and are chiefly lateral to the course of the longitudinal sinus. The arteries which supply this membrane with vessels for its own nourishment, for that of the contiguous bone, and for the perpetual exudation of the fluid, or halitus rather, which moistens or bedews its internal surface, may be divided into anterior, middle, and posterior. The first proceeds from the ophthalmic and ethmoidal branches; the second from the internal maxillary and superior pharyngeal; the posterior from the occipital and vertebral arteries.

The principal artery of the dura mater, named, by way of distinction, the great artery of the dura mater, is derived from the internal maxillary artery, a branch of the external carotid. It is called the spinalis, or spheno-spinalis, from its passing into the head through the spinous hole of the sphenoid bone, or meninga media, from its relative situation, as it rises in the great middle fossa of the skull. This artery, though it sometimes enters the skull in two branches, usually enters in one considerable branch, and divides, soon after it reaches the dura mater, into three or four branches, of which the anterior is the largest; and these spread their ramifications beautifully upon the dura mater, over all that part which is opposite to the anterior, middle and posterior lobes of the brain. Its larger trunks run upon the internal surface of the parietal bone, and are sometimes for a considerable space buried in its substance. The extreme branches of this artery extend so as to inosculate with the anterior and posterior arteries of the dura mater; and through the bones (chiefly parietal and temporal bones,) they inosculate with the temporal and occipital arteries. The meningeal artery has been known to become aneurismal, and distended at intervals; it has formed an aneurism, destroying the bones and causing epilepsy.

Dura meninx. See *Dura mater.*

DWALE. See *Atropa belladonna.*

Dwarf elder. See *Sambucus ebulus.*

Dyo'ta. (From δυω, two, and ους, ωτος, an ear.) A chemical instrument with two ears, or handles.

DYSÆSTHE'SIA. (From δυς, difficulty, and αισθανομαι, to feel or perceive.) Impaired feeling.

Dysæsthesiæ. (The plural of *Dysæsthesia.*) The name of an order in the class *Locales* of Dr. Cullen's Nosology, containing these diseases, in which the senses are depraved, or destroyed, from a defect of the external organs.

Dysanago'gus. (From δυς, with difficulty, and αναγω, to subdue.) Viscid expectoration.

DYSCATAPO'TIA. (From δυς, and καταπινω, to drink.) A difficulty of swallowing liquids, which Dr. Mead thinks a more proper term than that generally used for canine madness, viz. hydrophobia; as it is more particularly descriptive of the affection under which the unhappy patients labour; for, in reality, they dread water from the difficulty of swallowing it.

DYSCINE'SIA. (From δυς, bad, and κινεω, to move.) Bad or imperfect motion.

Dyscinesiæ. The plural of *dyscinesia.*) Applied to an order in the class *Locales* of Cullen's Nosology; embracing diseases in which the motion is impeded, or depraved, from an imperfection of the organ.

DYSCOPHO'SIS. (Fram δυς, with difficulty, and κωφοω, to be deaf.) A defect in the sense of hearing.

DYSCRA'SIA. (From δυς, with difficulty, and κεραννυμι, to mix.) A bad habit of body.

DYSECŒ'A. (From δυς, difficulty, and ακοη, hearing.) *Cophosis.* Deafness. Hearing diminished, or destroyed. A genus of disease in the class *Locales*, and order *Dysæsthesiæ* of Cullen, containing two species: *Dysecœa organica*, which arises from wax in the meatus, injuries of the membrane, or inflammation and obstruction of the tube: *Dysecœa atonica*, when without any discernible injury of the organ.

Dyse'lcia. (From δυς, with difficulty, and ελκος, an ulcer.) An inveterate ulcer, or one difficult to heal.

Dyse'metus. (From δυς, with difficulty, and εμεω, to vomit.) A person not easily made to vomit.

DYSENTE'RIA. See *Dysentery.*

DYSENTERY. (*Dysenteria*, from δυς, difficulty, and εντερα, the bowels.) *Dissolutus morbus. Diarrhœa carnosa.* The flux. A genus of disease in the class *Pyrexiæ*, and order *Profluvia* of Cullen's Nosology. It is known by contagious pyrexia; frequent griping stools; tenesmus; stools, chiefly mucous, sometimes mixed with blood, the natural fæces being retained or voided in small, compact, hard substances, known by the name of scybala, loss of appetite, and nausea. It occurs chiefly in summer and autumn, and is often occasioned by much moisture succeeding quickly intense heat, or great drought; whereby the perspiration is suddenly checked, and a determination made to the intestines. It is likewise occasioned by the use of unwholesome and putrid food, and by noxious exhalations and vapours; hence it appears often in armies encamped in the neighbourhood of low marshy grounds, and proves highly destructive; but the cause which most usually gives rise to it, is a specific contagion; and when it once makes its appearance, where numbers of people are collected together, it not unfrequently spreads with great rapidity. A peculiar disposition in the atmosphere seems often to predispose or give rise to the dysentery, in which case it prevails epidemically.

It frequently occurs about the same time with autumnal intermittent and remittent fevers, and with these, it is often complicated.

The disease, however, is much more prevalent in warm climates than in cold ones; and in the months of August, September, and October, which is the rainy season of the year in the West Indies, it is very apt to break out and to become very general among the negroes on the different plantations in the colonies. The body having been rendered irritable by the great heat of the summer, and being exposed suddenly to much moisture with open pores, the blood is thereby thrown from the exterior vessels upon the interior, so as to give rise to dysenteries.

An attack of dysentery is sometimes preceded by loss of appetite, costiveness, flatulency, sickness at the stomach, and a slight vomiting, and comes on with chills, succeeded by heat in the skin, and frequency of the pulse. These symptoms are in general the forerunners of the griping and increased evacuations which afterwards occur.

When the inflammation begins to occupy the lower part of the intestinal tube, the stools become more frequent and less abundant; and, in passing through the inflamed parts, they occasion great pain, so that every evacuation is preceded by a severe griping, as also a rumbling noise.

The motions vary both in colour and consistence, being sometimes composed of frothy mucus, streaked with blood, and at other times of an acrid watery humour, like the washings of meat, and with a very fœtid smell. Sometimes pure blood is voided; now and then lumps of coagulated mucus, resembling bits of cheese, are to be observed in the evacuations, and in some instances a quantity of purulent matter is passed.

Sometimes what is voided consists merely of a mucus matter, without any appearance of blood, exhibiting that disease which is known by the name of dysenteria alba, or morbus mucosus.

Whilst the stools consist of these various matters, and are voided frequently, it is seldom that we can perceive any natural fæces among them, and when we do, they appear in small hard balls, called scybala, which being passed, the patient is sure to experience some temporary relief from the griping and tenesmus.

It frequently happens, from the violent efforts which are made to discharge the irritating matters, that a portion of the gut is forced beyond the verge of the anus, which, in the progress of the disease, proves a troublesome and distressing symptom; as does likewise the tenesmus, there being a constant inclination to go to stool, without the ability of voiding any thing, except perhaps a little mucus.

More or less pyrexia usually attends with the symptoms which have been described, throughout the whole of the disease, where it is inclined to terminate fatally; and is either of an inflammatory or putrid tendency. In other cases, the febrile state wholly disappears after a time, while the proper dysenteric symptoms probably will be of long continuance. Hence the distinction into acute and chronic dysentery.

When the symptoms run high, produce great loss of strength, and are accompanied with a putrid tendency and a fœtid and involuntary discharge, the disease often terminates fatally in the course of a few days; but when they are more moderate, it is often protracted to a considerable length of time, and so goes off at last by a gentle perspiration, diffused equally over the whole body; the fever, thirst, and griping then ceasing, and the stools becoming of a natural colour and consistence. When the disease is of long standing, and has become habitual, it seldom admits of an easy cure; and when it attacks a person labouring under an advanced stage of scurvy, or pulmonary consumption, or whose constitution has been much impaired by any other disorder, it is sure to prove fatal. It sometimes appears at the same time with autumnal intermittent and remittent fevers, as has been observed, and is then more complicated and difficult to remove.

Upon opening the bodies of those who die of dysentery, the internal coat of the intestines (but more particularly of the colon and rectum) appears to be affected with inflammation and its consequences, such as ulceration, gangrene, and contractions. The peritonæum, and other coverings of the abdomen, seem likewise, in many instances, to be affected by inflammation.

In the treatment of the acute dysentery, when not arising from contagion, but attended by considerable pyrexia and pain, in persons of a strong and full habit, it will be right to commence by a moderate venæsection; but, in general, leeches to the abdomen will abstract a sufficient quantity of blood followed by fomentations, or the warm bath, which may produce a powerful determination to the surface as well as counteract spasm; also blisters or rubefacients should not be neglected. With regard to internal remedies, a brisk emetic will often be adviseable, particularly where the tongue is very foul, the stomach loaded, or marks of congestion in the liver appear: it may also, by inducing diaphoresis, materially check the violence of the symptoms, nay, sometimes cut short the disease at once. The next object is effectually to clear out the bowels: for which purpose calomel, joined with opium in quantity sufficient to relieve the pain may be given, and followed up by castor oil, neutral salts, &c. till they operate. In the mean time, mucilaginous demulcents may help to moderate the irritation. When the bowels have been thoroughly evacuated, it will be important to procure a steady determination to the surface, and the compound powder of ipecacuanha is perhaps the best medicine; assisted by warm clothing, friction, exercise, &c. Should the liver not perform its office properly, the continued use of mercury may be necessary; to restore the strength, and relieve dyspeptic symptoms, tonics and antacids will be useful, with a mild nutritious diet; and great care must be taken to obviate accumulation of fæces. In the chronic form of the disease, demulcents and sedatives may be freely employed by the mouth, or in the form of clyster; the bowels may be occasionally relieved by rhubarb, or other mild aperients; mercury should be cautiously employed, where the discharge of bile is indicated, or if that cannot be borne, nitric acid may be tried; and besides great attention to regimen, as in the decline of acute dysentery, mild astringents, with tonics, &c. may contribute materially to the recovery of the patient.

DYSEPULO′TICUS. (From δυς, with difficulty, and επυλοω, to cicatrize.) *Dysepulotus.* An inveterate ulcer difficult to be healed.

DYSHÆMORRHO′IS. (From δυς, with difficulty, and αιμορροις, the piles.) Suppression of the bleeding from piles.

DYSLO′CHIA. (From δυς, difficulty, and λοχια, the lochia.) A suppression of the lochia.

DYSMENORRHÆ′A. (From δυς, with difficulty, and μηνορροια, the menses.) A difficult or painful menstruation, accompanied with severe pains in the back, loins, and bottom of the belly.

DYSO′DES. (From δυς, bad, and οζω, to smell.) 1. A bad smell. Fœtid.

2. Hippocrates applies it to a fœtid disorder of the small intestines.

3. The name of a malagma and acopon in Galen and Paulus Ægineta.

DYSO′PIA. (From δυς, bad, and ωψ, an eye.) *Parorasis.* Difficult sight. Sight depraved, requiring one certain quantity of light, one particular distance, or one position. A genus of disease in the class *Locales*, and order *Dysæsthesiæ* of Cullen, containing the five following species:

1. *Dysopia tenebrarum*, called also *Amblyopia crepuscularis*, requiring objects to be placed in a strong light.

2. *Dysopia luminis*, likewise termed *Amblyopia meridiana*, objects only discernible in a weak light.

3. *Dysopia dissitorum*, in which distant objects are not perceived.

4. *Dysopia proximorum*, or *Dysopia amblyopia*, in which objects too near are not perceived.

5. *Dysopia lateralis*, called also *Amblyopia luscorum*, in which objects are not seen unless placed in an oblique position.

DYSORE'XIA. (From δυς, bad, and ορεξις, appetite.) A depraved appetite.

DYSOREXIÆ. (The plural of *Dysorexia*.) The name of an order in the class *Locales* of Cullen's Nosology, which he divides into two sections, appetitus erronei, and deficientes.

DYSPE'PSIA. (From δυς, bad, and ϖεπτω, to concoct.) *Apepsia*. Indigestion. Dr. Cullen arranges this genus of disease in the class *Neuroses*, and order *Adynamiæ*. It chiefly arises in persons between thirty and forty years of age, and is principally to be met with in those who devote much time to study, or who lead either a very sedentary or irregular life. A great singularity attendant on it is, that it may and often does continue a great length of time, without any aggravation or remission of the symptoms.

Great grief and uneasiness of mind, intense study, profuse evacuations, excess in venery, hard drinking, particularly of spirituous liquors, and of tea, tobacco, opium, and other narcotics, immoderate repletion, and over distention of the stomach, a deficiency in the secretion of the bile, or gastric juice, and the being much exposed to moist and cold air, when without exercise, are the causes which usually occasion dyspepsia.

A long train of nervous symptoms generally attend on this disease, such as a loss of appetite, nausea, heart-burn, flatulency, acid, fœtid, or nidorous eructations, a gnawing in the stomach when empty, a sense of constriction and uneasiness in the throat, with pain in the side, or sternum, so that the patient at times can only lie on his right side; great costiveness, habitual chilliness, paleness of the countenance, languor, unwillingness to move about, lowness of spirits, palpitations, and disturbed sleep.

The number of these symptoms varies in different cases, with some, being felt only in part; in others, being accompanied even with additional ones, equally unpleasant, such as severe transient pains in the head and breast, and various affections of the sight, as blindness, double vision, &c.

Dyspepsia never proves fatal, unless when, by a very long continuance, it produces great general debility and weakness; and so passes into some other disease, such as dropsy; but it is at all times very difficult to remove, but more particularly so in warm climates.

The morbid appearances to be observed on dissections of this disease, are principally confined to that part of the stomach which is called the pylorus; which is often found either in a contracted, scirrhous, or ulcerated state. In every instance, the stomach is perceived to be considerably distended with air.

The treatment of dyspepsia consists, 1. In obviating the several exciting causes. 2. In relieving urgent symptoms, some of which may tend to prolong the disease. 3. In restoring the tone of the stomach, or of the general system, and thus getting rid of the liability to relapse.

I. In fulfilling the first indication, we are often much circumscribed by the circumstances or habits of the patient; and particularly when they have been accustomed to drink spirits, which they can hardly relinquish, or only in a very gradual manner. The diet must be regulated by the particular form of the disease: in those who are liable to acidity, it should be chiefly of an animal nature, with the least acescent vegetable substances, and for drink, toast and water, or soda water, adding a little brandy, is really necessary; where the opposite, or septic tendency appears, which happens especially in persons of a florid complexion, it should consist principally of vegetable matter, particularly the ripe subacid fruits, with the meat of young animals occasionally, and if plain water be not agreeable, table-beer, cyder, &c. may be allowed for drink; and in those of the phlegmatic temperament the most nutritious and digestible articles must be selected, mostly of an animal nature, assisted by the warmer condiments, and the more generous fermented liquors in moderation. It will be generally better to take food oftener, rather than to load the stomach too much at once; but more than four meals a day can hardly be requisite; if at any other time a craving should occur, a crust of bread or a piece of biscuit may be eaten.

II. Among the symptoms requiring palliation, heart-burn is frequent, resulting from acrimony in the stomach, and to be relieved by antacid, or antiseptic remedies, according to circumstances, or diluents and demulcents may answer the purpose. A sense of weight at the stomach, with nausea, may occasionally indicate a gentle emetic; but will be less likely to occur if the bowels are kept regular. Flatulence may be relieved by aromatics, æther, &c.; and these will be proper for spasmodic, or nervous pains; but if ineffectual, opium should be had recourse to. Vomiting is generally best checked by carbonic acid. When diarrhœa occurs, the aromatic confection is mostly proper, sometimes with a little opium. But the bowels are much more commonly confined, and mild cathartics should be frequently exhibited, as castor oil, rhubarb, aloes, &c.; sometimes the more active, where these do not answer. In those of a florid complexion a laxative diet, with the supertartrate of potassa, or other saline cathartic occasionally, may agree better: and where the liver is torpid, mercurials should be resorted to.

III. The third object is to be attempted by tonics, particularly the aromatic bitters, the mineral acids, or the preparations of iron; by the cold bath prudently regulated; by gentle exercise steadily persevered in, particularly walking or riding on horseback; by a careful attention to the diet; by seeking a pure mild air, keeping regular hours, with relaxation and amusement of the mind, &c.

DYSPERMATI'SMUS. (From δυς bad, and σπερμα, seed.) *Agenesia*. Slow, or impeded emission of semen, during coition, insufficient for the purpose of generation. A genus of disease in the class *Locales*, and order *Epischeses* of Cullen. The species are:

1. *Dyspermatismus urethralis*, when the obstruction is in the urethra.

2. *Dyspermatismus nodosus*, when a tumour is formed in either corpus cavernosum penis.

3. *Dyspermatismus præputialis*, when the impediment is from a straightness of the orifice of the præpuce.

4. *Dyspermatismus mucosus*, when the urethra is obstructed by a viscid mucus.

5. *Dyspermatismus hypertonicus*, when there is an excess of erection of the penis.

6. *Dyspermatismus epilepticus*, from epileptic fits coming on during coition.

7. *Dyspermatismus apractodes*, from a want of vigour in the genitals.

8. *Dyspermatismus refluus*, in which the semen is thrown back into the urinary bladder.

DYSPHA'GIA. (From δυς, with difficulty, and φαγω, to eat.) A difficulty of deglutition. A genus of disease in Good's Nosology, embracing five species, *Dysphagia constricta*; *atonica*; *globosa*; *uvulosa*; *linguosa*.

DYSPHO'NIA. (From δυς, bad, and φωνη, the voice.) A difficulty of speaking. Dissonant voice. The sound of the voice imperfect, or depraved. A genus of disease in Good's Nosology, embracing three species, *Dysphonia susurrans*, *puberans*, and *immodulata*.

DYSPHORIA. (From δυς, and φορεω, *gesto.*) Restlessness. A genus of disease in Good's Nosology, it has two species, *Dysphorea simplex* and *anxietas*.

DYSPNŒ'A. (From δυς, difficult, and πνεω, to breath.) *Dyspnoon*. Difficult respiration, without sense of stricture, and accompanied with cough through the whole course of the disease. A genus of disease in the class *Neuroses* and order *Spasmi* of Cullen. He distinguishes eight species.

1. *Dyspnœa catarrhalis*, when with a cough there are copious discharges of viscid mucus, called also *asthma catarrhale*, *pneumodes*, *pneumonicum*, and *pituitosum*.

2. *Dyspnœa sicca*, when there is a cough without any considerable discharge.

3. *Dyspnœa aërea*, when the disease is much increased by slight changes of the weather.

4. *Dyspnœa terrea*, when earthy or calculous matters are spit up.

5. *Dyspnœa aquosa*, when there is a scarcity of urine and œdematous feet, without the other symptoms of a dropsy in the chest.

6. *Dyspnœa pinguedinosa*, from corpulency.

7. *Dyspnœa thoracica*, when parts surrounding the chest are injured, or deformed.

8. *Dyspnœa extrinseca*, from manifest external causes.

DY'SPNOON. See *Dyspnœa*.

DYSRA'CHITIS. The name of a plaster.

DYSTHETICA. (Δυσθετικα, an ill-conditioned state of the body.) The name of the fourth order of the class *Hæmatica* in Good's Nosology. Cachexies. Its genera are *Plethora*; *Hæmorrhagia*; *Marasmus*; *Struma*; *Carcinus*; *Lues*; *Elephantius*; *Bucnemia*; *Catacausis*; *Porphyra*; *Exangia*; *Gangrena*; *Ulcus*.

DYSTHY'MIA. (From δυς, bad, and θυμος, mind.) Insanity.

DYSTO'CHIA. (From δυς, with difficulty, and τικτω, to bring forth.) Difficult labour.

DYSTŒCHI'ASIS. (From δυς, bad, and ϛοιχος, order. An irregular disposition of the hairs in the eyelids.

DYSU'RIA. (From δυς, difficulty, and ουρον, urine.) *Stillicidium*; *Ardor urinæ*; *Culbicio*. A suppression or difficulty in discharging the urine. A total suppression is called ischuria; a partial suppression, dysuria: and this may be with or without heat. When there are frequent, painful, or uneasy urgings to discharge the urine, and it passes off only by drops, or in very small quantities, the disease is called strangury. When a sense of pain, or heat, attends the discharge, it passes with difficulty, and is styled ardor urinæ, heat of the urine. The dysuria is acute, or chronic. Dr. Cullen places this disease in the class *Locales*, and order *Epischeses*, containing six species:

1. *Dysuria ardens*, with a sense of heat, without any manifest disorder of the bladder.

2. *Dysuria spasmodica*, from spasm.

3. *Dysuria compressionis*, from a compression of the neighbouring parts.

4. *Dysuria phlogistica*, from violent inflammation.

5. *Dysuria calculosa*, from stone in the bladder.

6. *Dysuria mucosa*, from an abundant secretion of mucus.

The causes which give rise to these diseases are, an inflammation of the urethra, occasioned either by venereal sores, or by the use of acrid injections, tumour, ulcer of the prostate gland, inflammation of the kidneys, or bladder, considerable enlargements of the hæmorrhoidal veins, a lodgment of indurated fæces in the rectum, spasm at the neck of the bladder, the absorption of cantharides, applied externally or taken internally, and excess in drinking either spirituous or vinous liquors; but particles of gravel, sticking at the neck of the bladder, or lodging in the urethra, and thereby producing irritation, prove the most frequent cause. Gouty matter falling on the neck of the bladder, will sometimes occasion these complaints.

In dysury, there is a frequent inclination to make water with a smarting pain, heat, and difficulty in voiding it, together with a sense of fulness in the region of the bladder. The symptoms often vary, however, according to the cause which has given rise to it. If it proceeds from a calculus in the kidney or ureter, besides the affections mentioned, it will be accompanied with nausea, vomiting, and acute pains in the loins and region of the ureter and kidney of the side affected. When a stone in the bladder, or gravel in the urethra, is the cause, an acute pain will be felt at the end of the penis, particularly on voiding the last drops of urine, and the stream of water will either be divided into two, or be discharged in a twisted manner, not unlike a cork-screw. If a scirrhus of the prostate gland has occasioned the suppression or difficulty of urine, a hard indolent tumour, unattended with any acute pain, may readily be felt in the perinæum, or by introducing the finger into the rectum.

E.

EAGLE STONE. An argi'laceous iron stone.

EAR. *Auris*. The ear is the organ of hearing. It is situated at the side of the head, and is divided into external and internal ear. The *auricula*, or *pinna*, commonly called the ear, constitutes the external part. It is of a greater or less size, according to the individual. Its external face, which, in a well-formed ear, is a little anterior, presents five eminences, the *helix*, *antihelix*, *tragus*, *anti-tragus*, *lobula*; and three cavities, those of the *helix*, *fossa*, *navicularis*, *concha*.

The pinna is formed of a *fibrous cartilage*, elastic and pliant; the skin which covers it is thin and dry; adheres to the fibro-cartilage by a cellular tissue, which is compact, and contains very little adipose substance: the lobule alone contains it in considerable quantity. There are seen under the skin a number of sebaceous follicles, which furnish a micaceous white matter, that produces the polish and suppleness of the skin.

There are also seen, upon the different projections of the cartilaginous ear, certain muscular fibres, to which the name of *muscles* have been given, but which are only *vestigia*. The pinna, receiving many vessels and nerves, is very sensible, and easily becomes red. It is fixed to the head by the cellular tissue, and by muscles, which are called, according to their position, *anterior*, *superior*, and *posterior*. These muscles are much developed in many animals: in man they may be considered as simple vestiges.

The *meatus auditorius* extends from the *concha* to the membrane of the *tympanum;* its length, variable, according to age, is from ten to twelve lines in the adult; it is narrower in the middle than at the ends; it presents a slight curve above, and in front. Its external orifice is commonly covered with hairs, like the entrance to the other cavities. It is composed of an osseous part, of a fibro-cartilaginous substance, which is confounded with that of the pinna, of a fibrous part, which completes it above. The skin sinks into it, becoming thinner, and terminates in covering the external surface of the membrane of the *tympanum*. Below this skin exist a great number of sebaceous follicles, which furnish the *cerumen*, a yellow, bitter matter.

The middle ear comprehends the cavity of the tympanum, the little bones which are contained in this cavity, the mastoid cells, the Eustachian tube, &c.

The *tympanum* is a cavity which separates the external from the internal ear. Its form is that of a portion of a cylinder, but a little irregular. Its external partition presents, on the upper part, the *fenestra ovalis*, which communicates with the vestibule, and which is formed by a membrane; immediately below, a projection which is called *promontory;* below this projection, a little groove, which lodges a small nerve; still lower, an opening called the *fenestra rotunda*, which corresponds to the external winding of the cochlea: and which is also shut by a membrane. The external side presents the *membrani tympani*. This membrane is directed obliquely downward and inward; it is bent, very slender and transparent, covered on the outside by a continuation of the skin, on the inside by the narrow membrane which covers the tympanum; it is also covered on this side by the nerve called *chorda tympani:* its centre serves as a point of fixation for the extremity of the handle of the malleus; its circumference is fixed to the bony extremity of the meatus auditorius: it adheres equally in every point, and presents no opening that might admit a communication between the external and middle ear. Its tissue is dry, brittle, and has nothing analogous in the animal economy; there are neither fibres, vessels, nor nerves, found in it. The circumference of the tympanum presents, in the fore-part, 1st, The opening of the Eustachian tube, by which the cavity communicates with the superior part of the pharynx; 2dly, The opening by which the tendon of the internal muscle of the malleus enters. Behind are seen, 1st, The opening of the mastoid cells,—irregular winding cavities, which are formed in the mastoid process, and which are always filled with air; 2dly, The pyramid, a little hollow projection, which lodges the muscle of the *stapes;* 3dly, The opening by which the *chorda tympani* enters into the hollow of the tympanum. Below, the tympanum presents a slit, called *glenoid*, by which the tendon of the anterior muscle of the *malleus* enters, and the *chorda tympani* passes out, and goes to unite itself with the lingual nerve of the fifth pair.

Above, the circumference presents only a few small openings, by which blood-vessels pass. The cavity of the tympanum, and all the canals which end there, are covered with a very slender mucous membrane: this cavity, which is always full of air, contains besides four small bones, (the *malleus, incus, os orbiculare*, and *stapes*,) which form a chain from the membrana tympani to the fenestra ovalis, where the base of the stapes is fixed. There are some little muscles for the purpose of moving this osseous chain, of stretching and slackening the membranes to which they are attached: thus, the internal muscle of the malleus draws it forward, bends the chain in this direction, and stretches the membranes; the anterior muscle produces the contrary effect: it is also supposed that the small muscle which is placed in the pyramid, and which is attached to the neck of the *stapes*, may give a slight tension to the chain, in drawing it towards itself.

The *internal ear*, or *labyrinth*, is composed of the *cochlea*, of the *semicircular canals*, and of the *vestibule*.

The cochlea is a bony cavity, in form of a spiral, from which it has taken its name. This cavity is divided into two others, called the *gyri* of the cochlea, and which are distinguished into external and internal. The partition which separates them is a plate set edgeways, and which in its whole length is partly bony, and partly membranous. The external gyration communicates by the fenestra rotunda with the cavity of the tympanum; the internal gyration ends in the vestibule.

The *semicircular canals* are, three cylindrical cavities, bent in a semicircular form, two of which are disposed horizontally, and the others vertically. These canals terminate by their extremities in the vestibule. They contain bodies of a grey colour, the extremities of which are terminated by swellings.

The *vestibule* is the central cavity, the point of union of all the others. It communicates with the tympanum by the fenestra ovalis, with the internal gyration of the cochlea, with the semicircular canals, and with the internal meatus auditorius, by a great number of little openings.

The whole of the cavities of the internal ear are hollowed out of the hardest part of the petrous portion of the temporal bone: they are covered with an extremely thin membrane, and are full of a very thin and limpid fluid, called *Liquor of Cotunnius*, which can flow out by two narrow apertures, known by the name of the *aquæducts of the cochlea*, and *of the vestibule:* they contain besides, the acoustic nerve.

The *acoustic nerve* proceeds from the fourth ventricle; it enters into the labyrinth by the holes that the internal auditory meatus presents in its bottom. Having entered into the vestibule, it separates itself into a number of branches, one of which remains in the vestibule, another enters into the cochlea, and two go to the semicircular canals. Scarpa has very minutely described the distribution of these different branches in the cavities of the internal ear.

In terminating this short description, we remark that the internal and middle ear are traversed by several nervous threads, the presence of which is, perhaps, useful to hearing. It is known that the facial nerve proceeds a considerable space in a canal of the petrous portion. In this canal it receives a small thread of the vidian nerve; it furnishes the chorda tympani, which attaches itself to this membrane. There are two other nervous inosculations in the ear; to one of which Ribes called the attention of anatomists not long since; the other was recently discovered by Jacobson.

Ear-wax. See *Cerumen aurium.*

EARI'TES. Hæmatites, or blood-stone.

EARTH. *Terra.* Although there seems to be an almost infinite variety of earthy substances scattered on the surface of this globe, yet when we examine them with a chemical eye, we find, not without surprise, that all the earth and stones which we tread under our feet, and which compose the largest rocks, as well as the numerous different specimens which adorn the cabinets of the curious, are composed of a very few simple or elementary earths. "Analysis had shown, that the various stony or pulverulent masses, which form our mountains, valleys, and plains, might be considered as resulting from the combination or intermixture, in various numbers and proportions, of nine primitive earths, to which the following names were given:

1. Barytes. 2. Strontites. 3. Lime. 4. Magnesia. 5. Alumina, or clay. 6. Silica. 7. Glucina. 8. Zirconia. 9. Yttria.

Alkalies, acids, metallic ores, and native metals, were supposed to be of an entirely dissimilar constitution.

The brilliant discovery of Sir H. Davy, in 1808, of the metallic bases of potassa, soda, barytes, strontites, and lime, subverted the ancient ideas regarding the earths, and taught us to regard them as all belonging, by most probable analogies, to the metallic class.

To the above nine earthy substances, Berzelius has lately added a tenth, which he calls *thorina.* Whatever may be the revolutions of chemical nomenclature, mankind will never cease to consider as *earths,* those solid bodies composing the mineral strata, which are incombustible, colourless, not convertible into metals by all the ordinary methods of reduction, or when reduced by scientific refinements, possessing but an evanescent metallic existence, and which either alone, or at least when combined with carbonic acid, are insipid and insoluble in water.

Earth, absorbent. See *Absorbent.*

Earth, aluminous. See *Alumina.*

Earth, animal calcareous. This term is applied to crab's-claws, &c. which contain calcareous earth, and are obtained from the animal kingdom.

Earth, argillaceous. See *Alumina.*

Earth-bath. A remedy recommended by some writers on the continent, as a specific in consumption.

Earth, bolar. See *Bole.*

Earth, fullers'. *Cimolia purpurescens.* A compact bolar earth, commonly of a greyish colour. It is sometimes applied by the common people to inflamed breasts, legs, &c. with a view of cooling them.

Earth, heavy. See *Barytes.*

Earth, Japan. See *Acacia catechu.*

Earth, mineral calcareous. Those calcareous earths which are obtained from the mineral kingdom. The term is applied in opposition to those obtained from animals.

Earth-nut. See *Bunium bulbocastanum.*

Earth, sealed. *Terra sigillata.* Little cakes of earths, which are stamped with impressions. They were formerly in high estimation as absorbents, but now fallen into disuse.

Earth-worm. See *Lumbricus terrestris.*

Eaton's styptic. French brandy highly impregnated with calcined green vitriol. A remedy for checking hæmorrhages.

Eau-de-luce. See *Spiritus ammoniæ succinatus.*

Eau-de-rabel. This is composed of one part of sulphurous acid to three of rectified spirit of wine. It is much used in France, when diluted, in the cure of gonorrhœas, leucorrhœa, &c.

EBEL. The seeds of sage, or of juniper.

EBE'SMECH. Quicksilver.

EBI'SCUS. See *Hibiscus abelmoschus.*

EBSEMECH. Quicksilver.

EBULLI'TION. (*Ebullitio.* From *ebullio,* to bubble up.) Boiling. This consists in the change which a fluid undergoes from a state of liquidity to that of an elastic fluid, in consequence of the application of heat, which dilates and converts it into vapour.

E'BULUS. (From *ebullio,* to make boil: so called because of its supposed use in purifying the humours of the body.) See *Sambucus ebulus.*

ECBO'LICA. (From εκβαλλω, to cast out.) Medicines which cause abortion.

ECBO'LIOS. (From εκβαλλω, to cast out.) Miscarriage.

ECBRA'SMATA. (From εκβραζω, to be very hot.) *Ecchymata.* Painful fiery pimples in the face, or surface of the body.

ECBRA'SMUS. (From εκβραζω, to become hot.) Fermentation.

ECBYRSO'MATA. (From εκ, and βυρσα, the skin.) Protuberances of the bones at the joints, which appear through the skin.

ECCATHA'RTICA. (From εκκαθαιρω, to purge outwards.) According to Gorræus, eccathartics are medicines which open the pores of the skin; but in general they are understood to be deobstruents. Sometimes expectorants are thus called, and also purgatives. An obsolete term.

ECCHYLO'MA. (From εκ, and χυλος, juice.) An extract.)

ECCHY'MATA. (From εκχυω, to pour out.) See *Ecbrasmata.*

ECCHYMO'MA. (Εκχυμωμα; from εκχυω, to pour out.) *Ecchymosis; Crustula; Sugillatio.* Extravasation. A black and blue swelling, either from a bruise or spontaneous extravasation of blood. A genus of disease in the class *Locales,* and order *Tumores* of Cullen.

ECCHYMOMA ARTERIOSUM. The false aneurism.

ECCHYMO'SIS. See *Ecchymoma.*

E'CCLISIS. (From εκκλινω, to turn aside.) A luxation or dislocation.

E'CCOPE. (From εκκοπτω, to cut off.) The cutting off any part.

ECCO'PEUS. (From εκκοπτω, to cut off.) An ancient instrument, the raspatory, used in trepanning.

ECCOPRO'TIC. (*Eccoproticus;* from εκ, and κοπρος, dung.) An opening medicine, the operation of which is very gentle; such as manna, senna, &c.

ECCRINOCRI'TICA. (From εκκρινω, to secrete, and κρινω, to judge.) Judgments formed from the secretions.

ECCRINOLO'GIA. (From εκκρίνω, to secrete, and λογος, a discourse.) *Eccrinologica.* The doctrine of secretions.

E'CCRISIS. (From εκκρινω, to secrete.) A secretion of any kind.

ECCRITICA. (From εκκρινω, to secern, or strain off.) Dr. Good applies this name to a class of diseases of the excernent system. It has three orders, viz. *Mesotica, Catotica, Acrotica.*

ECCYESIS. (From εκ, and κυησις, *gravidity.*) Extra uterine fœtation. The name of a genus of diseases in Good's Nosology. It has three species: *Eccyesis ovariæ, tubalis, abdominalis.*

ECCYMO′SIS. See *Ecchymoma.*

E′CDORA. (From εκδερω, to excoriate.) An excoriation; and particularly used for an excoriation of the urethra.

Ecdo′ria. (From εκδερω, to excoriate.) Medicines which excoriate and burn through the skin.

Echeco′llon. (From εχω, to have, and κολλα, glue.) *Echecollum.* Any topical glutinous remedy.

Echetro′sis. So Hippocrates calls the white briony.

ECHINATUS. Bristly. Applied in botany to any thing beset with bristles, as the pod of *Glycyrrhiza echinata,* and to the gourd seed-vessel, or *pepo.*

Echini′des. In Hippocrates it is mentioned as what he used for purging the womb with.

ECHINOPHTHA′LMIA. (From εχινος, a hedge-hog, and οφθαλμια, an inflammation of the eye.) An inflammation of that part of the eyelids, where the hairs bristle out like the quills of an echinus, or hedge-hog.

ECHINOPO′DIUM. (From εχινος, a hedge-hog, and πους, a foot; so named because its flowers resemble the foot of an urchin.) A species of broom or genista.

ECHI′NOPS. (From εχινος, as beset with prickles.) The name of a genus of plants. Class, *Syngenesia;* Order, *Polygamia segregata.*

Echinops sphærocephalus. The systematic name of the globe-thistle. *Crocodilion; Acanthalruca; Scabiosa carduifolia; Sphærocephala elatis; Echinopus.* It is raised in our gardens. The root and seeds are moderately diuretic, but not used.

Echi′nopus. See *Echinops.*

ECHINUS. 1. The hedge-hog, or *Erinaceus europæus* of Linnæus.

2. A genus in the Linnæan system, included in the molusca order of vermes.

3. The calcareous petrifaction of the sea hedge-hog.

4. The prominent points on the surface of the *pileus,* or upper part of the mushroom tribe, are called *echini.* See *Fungus.*

ECHIOIDES. (From εχις, a viper, and ειδος, resemblance.) The trivial name of some plants, from their supposed resemblance to the *Echium.*

E′CHIUM. (From εχις, a viper; so called because it was said to heal the stings of vipers.) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia.* Viper's bugloss.

Echium ægyptiacum. Wall bugloss. The *Asperugo ægyptiaca,* the root of which is sudorific, and is used with oil as a dressing for wounds.

E′CHOS. Ηχος. Sound. In Hippocrates it signifies the same as the tinnitus aurium, or noise in the ears.

E′CHYSIS. (From εχυω, to pour out.) A fainting or swooning.

ECLA′MPSIA. (From εκλαμπω, to shine.) See *Eclampsis.*

ECLA′MPSIS. (From εκλαμπω, to shine.) *Eclampsia.* It signifies a splendour, brightness, effulgence, flashing of light, scintillation. It is a flashing light, or those sparklings which strike the eyes of epileptic patients. Cœlius Aurelianus calls them *circuli ignei,* scintillations, or fiery circles. Though only a symptom of the epilepsy, Hippocrates puts it for epilepsy itself.

ECLE′CTIC. (*Eclecticus;* from εκλεγω, to select.) Archigenes and some others selected from all other sects what appeared to them to be the best and most rational; hence they were called *Eclectics,* and their medicine *Eclectic medicine.*

ECLE′CTOS. (From εκλειχω, to lick up.) A linctus, or soft medicine, like an electuary, to be licked up.

ECLE′GMA. (From εκλειχω, to lick.) A linctus, or form of medicine made by the incorporation of oils with syrups, and which is to be taken upon a liquorice stick.

E′CLYSIS. (From εκλυω, to dissolve.) An universal faintness.

ECMA′GMA. (From εκμασσω, to form together.) A mass of substances kneaded together.

ECPEPIE′MENOS. (From εκπιεζω, to press out.) An ulcer with protuberating lips.

ECPHLYSIS. (Εκφλυσις; from εκφλυζω, to boil, or bubble up, or over.) A blain or vesicular eruption. The name of a genus of disease in Good's Nosology. It has four species, viz. *Ecphlysis pompholex, herpes, rhypia,* and *eczema.*

ECPHRA′CTIC. (From εκφρασσω, to remove obstructions.) That which attenuates tough humours, so as to promote their discharge.

ECPHRA′XIS. (From εκφρασσω, to remove obstruction.) A perspiration, an opening of obstructed pores.

ECPHRONIA. (Εκφρωνη, or εκφροσυνη, from εηφρων, *extra mentem,* out of one's mind.) The name of a genus in Good's Nosology. Insanity and craziness. It has two species: *Ecphronia melancholia,* and *Ecphronia mania.*

E′CPHYAS. (From εκ, and φυω, to produce.) 1. An appendix, or excrescence.

2. The appendicula cæci vermiformis.

ECPHYMA. (From εκφυω, *educo, egero.*) A cutaneous excrescence. The name of a genus of diseases in Good's Nosology. Class, *Eccritica;* Order, *Acrotia.* It has four species, viz. *Ecphyma caruncula, verruca, clavus, and callus.*

E′cphyse. (From εκφυσαω, to blow out.) Flatus from the bladder through the urethra, and from the wound through the vagina.

Ecphyse′sis. (From εκφυσαω, to breathe through.) A quick expulsion of the air from the lungs.

E′CPHYSIS. (From εκφυω, to produce.)

1. An apophysis, or appendix.

2. A process.

Ecpie′sma. (From εκπιεζω, to press out.) A fracture of the skull, in which the bones press inwardly.

Ecpie′smos. (From εκπιεζω, to press out.) A disorder of the eye, in which the globe is almost pressed out of the socket by an afflux of humours.

Ecplero′ma. (From εκπληροω, to fill.) In Hippocrates they are hard balls of leather, or other substances, adapted to fill the arm-pits, while by the help of the heels, placed against the balls, and repressing the same, the luxated os humeri is reduced into its place.

ECPLE′XIS. (From εκπλησω, to terrify or astonish.) A stupor, or astonishment, from sudden external accidents.

E′cpnoe. (From εκπνεω, to breathe.) Expiration; that part of respiration in which the air is expelled from the lungs.

ECPTO′MA. (From εκπιπτω, to fall out.) 1. A luxation of a bone.

2. The expulsion of the secundines.

3. The falling off of gangrenous parts.

4. An hernia in the scrotum.

5. A falling down of the womb.

Ecpy'ctica. (From εκπυκαζω, to condense.) Medicines that render the fluids more solid.

ECPYE'MA. (From εκ, and πυον, pus.) A collection of pus, from the suppuration of a tumour.

ECPYESIS. (From εκπυω, to suppurate.) The name of a genus of diseases in Good's Nosology. Class, *Eccritica;* Order, *Acrotica.* Humid scalp. It has four species, *Ecpyesis impetigo, porrigo, ecthyma, scabies.*

Ecre'gma. (From εκρηγνυμι, to break.) A rupture.

Ecre'xis. (From εκρηγνυμι, to break.) A rupture. Hippocrates expresses by it a rupture or laceration of the womb.

Ecrhy'thmos. (From εκ, and ρυθμος, harmony.) A term applied to the pulse, and signifies that it is irregular.

E'croe. (From εκρεω, to flow out.) An efflux, or the course by which any humour which requires purging is evacuated.

Ecrueles. The French for scrophula.

E'crysis. (From εκρεω, to flow out.) In Hippocrates it is an efflux of the semen before it receives the conformation of a fœtus, and therefore is called an efflux, to distinguish it from abortion.

ECSARCO'MA. (From εκ, and σαρξ, flesh.) A fleshy excrescence.

E'CSTASIS. (*Ecstasis, eos.* f. Εκϛασις; from εξιϛαμαι, to be out of one's senses.) An ecstasy, or trance. In Hippocrates it signifies a delirium.

Ecstro'phius. (From εκϛρεφω, to invert.) An epithet for any medicine, that makes the blind piles appear outwardly.

Ecthely'nsis. (From εκθηλυνω, to render effeminate.) Softness. It is applied to the skin and flesh, when lax and soft, and to bandages, when not sufficiently tight.

Ecthli'mma. (From εκθλιβω, to press out against.) An ulceration caused by pressure of the skin.

Ecthli'psis. (From εκϛλιβω, to press out against.) Elision, or expression. It is spoken of swelled eyes, when they dart forth sparks of light.

E'CTHYMA. (*Ecthyma, atis.* n. εκθυειν, to rage, or break forth with fury.) A pustule or cutaneous eruption.

Ectillo'tica. (From εκτιλλω, to pull out.) Medicines which eradicate tubercles or corns, or destroy superfluous hair.

ECTO'PIA. (From εκτοπος, out of place.) Displaced.

Ectopiæ. (The plural of *ectopia.*) Parts displaced. An order in the class *locales* of Cullen's Nosology. See *Nosology.*

Ectrapeloga'stros. (From εκτρεπομαι, to degenerate, and γαϛηρ, a belly.) One who has a monstrous belly, or whose appetite is voraciously large.

Ectri'mma. (From εκτριβω, to rub off.) An excoriation. In Hippocrates it is an exulceration of the skin about the os sacrum.

E'ctrope. (From εκτρεπω, to divert, pervert, or invert.) It is any duct by which the humours are diverted and drawn off. In P. Ægineta it is the same as *Ectropium.*

ECTRO'PIUM. (From εκτρεπω, to evert.) An eversion of the eyelids, so that their internal surface is outermost.

There are two species of this disease: one produced by an unnatural swelling of the lining of the eyelids, which not only pushes their edges from the eyeball, but also presses them so forcibly, that they become everted; the other arising from a contraction of the skin covering the eyelid, or of that in the vicinity, by which means the edge of the eyelid is first removed for some distance from the eye, and afterwards turned completely outward, together with the whole of the affected eyelid.

The morbid swelling of the lining of the eyelids, which causes the first species of ectropium, arises mostly from a congenital laxity of this membrane, afterwards increased by chronic ophthalmies, particularly of a scrophulous nature, in relaxed, unhealthy, subjects; or else the disease originates from the small-pox affecting the eyes.

While the disease is confined to the lower eyelid, as it most commonly is, the lining of this part may be observed rising in the form of a semilunar fold, of a pale red colour like the fungous granulations of wounds, and intervening between the eye and eyelid, which latter it in some measure everts. When the swelling is afterwards occasioned by the lining of both the eyelids, the disease assumes an annular shape, in the centre of which the eyeball seems sunk, while the circumference of the ring presses and everts the edges of the two eyelids, so as to cause both great uneasiness and deformity. In each of the above cases, on pressing the skin of the eyelids with the point of the finger, it becomes manifest that they are very capable of being elongated, and would readily yield, so as entirely to cover the eyeball, were they not prevented by the intervening swelling of their membranous lining.

Besides the very considerable deformity which the disease produces, it occasions a continual discharge of tears over the cheek, and, what is worse, a dryness of the eyeball, frequent exasperated attacks of chronic ophthalmy, incapacity to bear the light, and, lastly, opacity and ulceration of the cornea.

The second species of ectropium, or that arising from a contraction of the integuments of the eyelids, or neighbouring parts, is not unfrequently a consequence of puckered scars, produced by a confluent small-pox, deep burns, or the excision of cancerous or encysted tumours, without saving a sufficient quantity of skin; or, lastly, the disorder is the effect of malignant carbuncles, or any kind of wound attended with much loss of substance. Each of these causes is quite enough to bring on such a contraction of the skin of the eyelids as to draw the parts towards the arches of the orbits, so as to remove them from the eyeball, and turn their edges outward. No sooner has this circumstance happened, than it is often followed by another one equally unpleasant, namely, a swelling of the internal membrane of the affected eyelids, which afterwards has a great share in completing the eversion. The lining of the eyelids, though trivially everted, being continually exposed to the air, and irritation of extraneous substances, soon swells, and rises up like fungus. One side of this fungus-like tumour covers a part of the eye-ball; the other pushes the eyelid so considerably outwards, that its edge is not unfrequently in contact with the margin of the orbit. The complaints induced by this second species of ectropium are the same as those brought on by the first; it being noticed, however, that in both cases, whenever the disease is very inveterate, the fungous swelling of the inside of the eyelids becomes hard, and as it were callous.

Although, in both species of ectropium, the lining of the eyelids seems equally swollen, yet the surgeon can easily distinguish to which of the two species the disease belongs. For, in the first, the skin of the eyelids, and adjoining parts, is not deformed with scars; and by pressing the everted eyelid with the point of the finger, the part would with ease cover the eye, were it not for the intervening fungous swelling. But in the second species of ectropium, besides the obvious cicatrix and contraction of the skin of the eyelids, or adjacent parts, when an effort is made to cover the eye with the everted eyelid, by pressing upon the latter part with the point of the finger, it does not give way so as completely to cover the globe, as it ought to do, only yielding for a certain extent: or it does not move in the least from its unnatural position, by reason of the integuments of the eyelids having been so extensively destroyed, that their margin has become adherent to the arch of the orbit.

ECTRO′SIS. (Εκτρωσις; from εκτιτρωσκω, to miscarry.) A miscarriage.

Ectro′tica. (From εκτιτρωσκω, to miscarry.) *Ectyrotica; Ectylotica.* Medicines which cause abortion.

Ectylo′tica. See *Ectillotica.*

Ectyro′tica. See *Ectrotica.*

ECZE′MA. (From εκζεω, to boil out.) *Eczesma.* A hot, painful eruption, or pustule.

Ede′lphus. The prognosis of a disease from the nature of elements.

E′des. Amber.

Ede′ssenum. An eye-water of tragacanth, gum-arabic, opium, &c.

E′detz. Amber.

E′dic. *Edich; Edir.* Iron.

E′dra. A fracture; also the lower part of the rectum.

EDULCORA′NTIA. (From *edulco*, to make sweet.) Edulcorants. Medicines which purify the fluids, by depriving them of their acrimony.

EFFERVESCENCE. (*Effervescentia*; from *effervesco*, to grow hot.) 1. That agitation which is produced by mixing substances together, which cause the evolution of a gas.

2. A small degree of ebullition.

E′ffides. Ceruss.

E′ffila. Freckles.

EFFLORESCENCE. (*Efflorescentia*; from *effloresco*, to blow as a flower.) 1. In *pathology*, it is used to express a morbid redness of the skin, and is generally synonymous with exanthema.

2. In *chemistry*, it means that effect which takes place when bodies spontaneously become converted into a dry powder. It is almost always occasioned by the loss of the water of crystallisation in saline bodies.

3. In *botany*, it is applied to express the blooming of flowers, and the time of flowering.

EFFLU′VIUM. (From *effluo*, to spread abroad.) See *Contagion.*

Effractu′ra. (From *effringo*, to break down.) A fracture, in which the bone is much depressed by the blow.

EFFUSION. (*Effusio*; from *effundo*, to pour out.) In pathology it means the escape of any fluid out of the vessel, or viscus, naturally containing it, and its lodgment in another cavity, in the cellular substance, or in the substance of parts. Effusion also sometimes signifies the morbid secretion of fluids from the vessels; thus physicians frequently speak of coagulable lymph being effused on different surfaces.

EGERAN. A sub-species of pyramidal garnet of a reddish brown colour.

Ege′ries. (From *egero*, to carry out.) *Egestio.* An excretion, or evacuation.

EGG. *Ovum.* The eggs of hens, and of birds in general, are composed of several distinct substances. 1. The shell or external coating, which is composed of carbonate of lime .72, phosphate of lime .2, gelatine .3. The remaining .23 are perhaps water. 2. A thin white and strong membrane, possessing the usual characters of animal substances. 3. The white of the egg, for which, see Albumen. 4. The yolk, which appears to consist of an oil of the nature of fat oils, united with a portion of serous matter, sufficient to render it diffusible in cold water, in the form of an emulsion, and concrescible by heat. Yolk of egg is used as the medium for rendering resins and oils diffusible in water. The eggs of poultry are chiefly used as food; the different parts are likewise employed in pharmacy and in medicine. The calcined shell is esteemed as an absorbent. The oil is softening, and is used externally to burns and chaps. The yolk renders oil miscible with water, and is triturated with the same view with resinous and other substances. Raw eggs have been much recommended as a popular remedy for jaundice.

Egrego′rsis. (From εγρηγορεω, to watch.) A watchfulness, or want of sleep.

Ei′lamis. (From ειλεω, to involve.) A membrane involving the brain.

Eile′ma. (From ειλεω, to form convolutions.) In Hippocrates, it signifies painful convolutions of the intestines from flatulence. Sometimes it signifies a covering. Vogel says, it is a fixed pain in the bowels, as if a nail was driven in.

Ei′leon. (From ειλεω, to wind.) Gorræus says it is a name of the intestinum ileum.

Ei′leos. (From ειλεω, to form convolutions.) The iliac passion.

Ei′sbole. (From εις, into, and βαλλω, to cast.) It signifies strictly an injection, but is used to express the access of a distemper, or of a particular paroxysm.

Ei′spnoe. (From εις, into, and πνεω, to breathe.) Inspiration of air.

EJACULA′NTIA. From *ejaculo*, to cast out.) *Ejaculatoria.* The vessels which convey the seminal matter secreted in the testicles to the penis. These are the epididymis, and the vasa deferentia; the vesiculæ seminales are the receptacles of the semen.

EJE′CTIO. (From *ejicio*, to cast out.) Ejection, or the discharging of any thing from the body.

Elaca′lli. The Indian name of a cathartic shrub, the *Euphorbia nerifolia* of Linnæus.

Elæa′gnon. (From ελαιον, oil, and αγνος, chaste.) See *Vitex agnus castus.*

Elæo′meli. (From ελαιον, oil, and μελι, honey.) A sweet purging oil, like honey.

ELÆOSA′CCHARUM. (From ελαιον, oil, and σακχαρον, sugar.) A mixture of an essential oil with sugar.

Elæoseli′num. See *Eleoselinum.*

ELAIN. The oily principle of solid fats, so named by its discoverer, Chevreuil, who dissolves tallow in very pure hot alkohol, separates the *stearin* by crystallisation, and then procures the *elain* by evaporation of the spirit. Braconnot has adopted a simpler, and probably a more exact method. By squeezing tallow between the folds of porous paper, the *elain* soaks into it, while the *stearin* remains. The paper being then soaked in water, and pressed, yields up its oily impregnation. Elaïn has very much the appearance and properties of vegetable oil. It is liquid at the temperature of 60°. Its smell and colour are derived from the solid fats from which it is extracted.

Elais guinee′nsis. A species of palm which grows spontaneously on the coast of Guinea, but is much cultivated in the West Indies. It is from this tree that the oil, called in the West Indies *Mackaw fat*, is obtained; and, according to some, the palm-oil, which is considered as an emollient and strengthener of all kinds of weakness of the limbs. It also is recommended against bruises, strains, cramps, pains, swellings, &c.

Elambica′tio. A method of analysing mineral waters.

Ela′nula. Alum.

ELAOLITE. A subspecies of pyramidal felspar.

ELAPHOBO′SCUM. (From ελαφος, a stag, and βοσκω, to eat: so called, because deer eat them greedily.) See *Pastinaca.*

ELAPHOSCO′RODON. (From ελαφος, the stag, and σκοροδον, garlic.) Stag's or viper's garlic.

E′laquir. Red vitriol.

E′las maris. Burnt lead.

Ela′sma. (From ελαυνω, to drive.) A lamina of any kind. A clyster-pipe.

ELASTIC. (*Elasticus;* from ελαστης, *impulsor*, or of ελαυνειν, to impel, to push.) Springy; having the power of returning to the form from which it has been forced to deviate, or from which it is withheld; thus, a blade of steel is said to be elastic, because if it is bent to a certain degree, and then let go, it will of itself return to its former situation; the same will happen to the branch of a tree, a piece of Indian rubber, &c. See *Elasticity.*

Elastic fluid. See *Gas.*

Elastic gum. See *Caoutchouc.*

ELASTICITY. *Elasticitas.* A force in bodies, by which they endeavour to restore themselves to the posture from whence they were displaced by any external force. To solve this property, many have recourse to the universal law of nature, attraction, by which the parts of solid and firm bodies are caused to cohere together: whereby, when hard bodies are struck or bent, so that the component parts are a little moved from one another, but not quite disjoined or broken off, nor separated so far as to be out of the power of the attracting force, by which they cohere together; they certainly must, on the cessation of the external violence, spring back with a very great velocity to their former state. But in this circumstance, the atmospherical pressure will account for it as well: because such a violence, if it be not great enough to separate the constituent particles of a body far enough to let in any foreign matter, must occasion many vacuola between the separated surfaces, so that upon the removal of the external force, they will close again by the pressure of the aerial fluid upon the external parts, *i. e.* the body will come again into its natural posture. The included air, likewise, in most bodies, gives that power of resilition upon their percussion.

If two bodies perfectly *elastic* strike one against another, there will be or remain in each the same relative velocity as before, *i. e.* they will recede with the same velocity as they met together. For the compressive force, or the magnitude of the stroke in any given bodies, arises from the relative velocity of those bodies, and is proportional to it, and bodies perfectly *elastic* will restore themselves completely to the figure they had before the shock, or, in other words, the restitutive force is equal to the compressive, and therefore must be equal to the force with which they came together, and consequently they must by elasticity recede again from each other with the same velocity. Hence, taking equal times before and after the shock, the distances between the bodies will be equal; and therefore the distances of them from the common centre of gravity, will in the same times, be equal. And hence the laws of percussion of bodies perfectly elastic are easily deduced.

ELATE′RIUM. (From ελαυνω, to stimulate or agitate: so named from its great purgative qualities.) See *Momordica elaterium.*

ELATHE′RIA. A name for the cascarilla bark.

ELATIN. The active principle of elaterium. See *Momordica elaterium.*

ELATI′NE. (From ελαττων, smaller, being the smaller species.) See *Antirrhinum elatine.*

ELATIO. Elevated, exalted. This term is applied in Good's Nosology, to a species of the genus *Alusio*, to designate mental extravagance.

Elati′tes. Bloodstone.

ELCO′SIS. (From ελκος, an ulcer.) A disease attended with fœtid, carious, and chronic ulcers. The term is seldom used.

ELDER. See *Sambucus.*

Elder Dwarf. See *Sambucus Ebulus.*

ELECAMPANE. See *Inula helenium.*

ELECTIVE. That which is done, or passes by election.

Elective affinity, double. See *Affinity double.*

Elective attraction. See *Affinity.*

Elective attraction, double. See *Affinity double.*

ELECTRICITY. (*Electricitas;* from *electrum*, ηλεκτρον, from ηλεκτωρ, the sun, because of its bright shining colour; or from ελκω, to draw, because of its magnetic power.) A property which certain bodies possess when rubbed, heated, or otherwise excited, whereby they attract remote bodies, and frequently emit sparks or streams of light. The ancients first observed this property in amber, which they called *Electrum*, and hence arose the word electricity.

"If a piece of sealing-wax and of dry warm flannel be rubbed against each other, they both become capable of attracting and repelling light bodies. A dry and warm sheet of writing-paper, rubbed with India rubber, or a tube of glass rubbed upon silk, exhibit the same phenomena. In these cases, the bodies are said to be *electrically excited;* and when in a dark room, they always appear luminous. If two pith-balls be electrified by touching them with the sealing-wax, or with the flannel, they repel each other; but if one pith-ball be electrified by the wax, and the other by the flannel, they attract each other. The same applies to the glass and silk: it shows a difference in the electricities of the different bodies, and the experiment leads to the conclusion, that *bodies similarly electrified repel each other; but that when dissimilarly electrified they attract each other.*

The term *electrical repulsion* is here used merely to denote the appearance of the phenomenon, the separation being probably referrible to the new attractive power which they acquire, when electrified, for the air and other surrounding bodies.

If one ball be electrified by sealing-wax rubbed by flannel, and another by silk rubbed with glass, those balls will repel each other; which proves that the electricity of the silk is the same as that of the sealing-wax. But if one ball be electrified by the sealing-wax and the other by the glass, they then attract each other, showing that they are oppositely electrified.

These experiments are most conveniently performed with a large downy feather, suspended by a silken thread. If an excited glass tube be brought near it, it will receive and retain its electricity; it will be first attracted and then repelled; and upon re-exciting the tube, and again approaching it, it will not again be attracted, but retain its state of repulsion; but upon approaching it with excited sealing-wax, it will instantly be attracted, and remain in contact with the wax till it has acquired its electricity, when it will be repelled, and in that state of repulsion it will be attracted by the glass. In these experiments, care must be taken that the feather remains freely suspended in the air, and touches nothing capable of carrying off its electricity.

The terms *vitreous* and *resinous* electricity were applied to these two phenomena; but Franklin, observing that the same electricity was not inherent in the same body, but that glass sometimes exhibited the same phenomena as wax, and *vice versâ*, adopted another term, and instead of regarding the phenomena as dependent upon two electric fluids, referred them to the presence of one fluid, in excess in some cases, and in deficiency in others. To represent these states, he used the terms *plus* and *minus*, *positive* and *negative*. When glass is rubbed with silk, a portion of electricity leaves the silk, and enters the glass; it becomes *positive*, therefore, and the silk *negative:* but when sealing-wax is rubbed with flannel, the wax loses, and the flannel gains; the former, therefore, is negative, and the latter positive. All bodies in nature are thus regarded as containing the electric fluid, and when its equilibrium is disturbed, they exhibit the phenomena just described. The substances enumerated in the following table become positively electrified when rubbed with those which follow them in the list; but with those which precede them they become negatively electrical.—*Biot, Traité de Physique*, tom. ii. p. 220.

Cat's-skin.
Polished glass.
Woollen cloth.
Feathers.
Paper.
Silk.
Gum lac.
Rough glass.

Very delicate pith-balls, or strips of gold leaf, are usually employed in ascertaining the presence of electricity; and by the way in which their divergence is affected by glass or sealing-wax, the kind or state of electricity is judged of. When properly suspended or mounted for delicate experiments, they form an *elettrometer* or *electroscope*. For this purpose, the slips of gold leaf are suspended by a brass cap and wire in a glass cylinder: they hang in contact when unelectrified, but when electrified they diverge.

When this instrument, as usually constructed, becomes in a small degree damp, its delicacy is much diminished, and it is rendered nearly useless.

The kind of electricity by which the gold leaves are diverged may be judged of by approaching the cap of the instrument with a stick of excited sealing-wax; if it be *negative*, the divergence will increase; if *positive*, the leaves will collapse, upon the principle of the mutual annihilation of the opposite electricities, or that bodies similarly electrified repel each other, but that when dissimilarly electrified, they become mutually attractive.

Some bodies suffer electricity to pass through their substance, and are called *conductors*. Others only receive it upon the spot touched, and are called *non-conductors*. The former do not, in general, become electrified by friction, and are called *non-electrics;* the latter, on the contrary, are *electrics*, or acquire electricity by friction. They are also called *insulators*. The metals are all conductors; dry air, glass, sulphur, and resins, are non-conductors. Water, damp wood, spirit of wine, damp air, and some oils, are imperfect conductors.

Rarified air admits of the passage of electricity; so does the Jarricellian vacuum: hence, if an electrified body be placed under the receiver of the air-pump, it loses its electricity during exhaustion. So that the air, independent of its non-conducting power, appears to influence the retentive properties of bodies, in respect to electricity, by its pressure.

There appears to be no constant relation between the state of bodies and their conducting powers: among solids, metals are conductors; but gums and resins are non-conductors: among liquids, strong alkaline acid, and saline solutions, are good conductors; pure water is an imperfect conductor; and oils are non-conductors; solid wax is almost a non-conductor; but when melted a good one.

Conducting powers belong to bodies in the most opposite states; thus, the flame of alkohol and ice are equally good conductors. Glass is a non-conductor when cold, but conducts when red-hot: the diamond is a non-conductor; but pure and well-burned charcoal is among the best conductors.

There are many mineral substances which show signs of electricity when heated, as the tourmalin, topaz, diamond, boracite, &c., and in these bodies the different surfaces exhibit different electrical states.

Whenever one part of a body, or system of bodies, is positive, another part is invariably negative; and these opposite electrical states are always such as exactly to neutralize each other. Thus, in the common electrical machine, one conductor receives the electricity of the glass-cylinder, and the other that of the silk-rubber, and the former conductor is positive, and the latter negative; but if they be connected, all electrical phenomena cease.

Electricians generally employ the term *quantity* to indicate the absolute quantity of electric power in any body, and the term *intensity*, to signify its power of passing through a certain stratum of air, or other ill-conducting medium.

If we suppose a charged Leyden phial to furnish a spark, when discharged, of one inch in length, we should find that another uncharged Leyden phial, the inner and outer coating of which were communicated with those of the former, would, upon the same quantity of electricity being thrown in, reduce the length of the spark to half an inch; here the *quantity* of electricity remaining the same, its *intensity* is diminished by one-half, by its distribution over the larger surface.

It is obvious that the extension of surface alluded to in the last paragraph will be attended with a greater superficial exposure to the unelectrified air; and hence it might be expected that a similar diminution of intensity would result from the vicinity of the electrified surface to the ground, or to any other body of sufficient magnitude in its ordinary state. That this is the case, may be shown by diverging the leaves of the gold leaf electrometer, and in that state approaching the instrument with an uninsulated plate, which, when within half an inch of the electrometer-plate, will cause the leaves to collapse; but, on removing the uninsulated plate, they will again diverge, in consequence of the electricity regaining its former intensity. The same fact is shown by the condensing electrometer.

The power of the Leyden jar is proportioned to its surface; but a very large jar is inconvenient and difficult to procure; the same end is attained by arranging several jars, so that by a communication existing between all their interior coatings, their exterior being also united, they may be charged and discharged as one jar. Such a combination is called an electrical *battery*, and is useful for exhibiting the effect of accumulated electricity.

The discharge of the battery is attended by a considerable report, and if it be passed through small animals, it instantly kills them; if through fine metallic wires, they are ignited, melted, and burned; and gun-powder, cotton sprinkled with powdered resin, and a variety of other combustibles, may be inflamed by the same means.

There are many other sources of electricity than those just noticed. When glass is rubbed by mercury, it becomes electrified, and this is the cause of the luminous appearance observed when a barometor is agitated in a dark room, in which case flashes of light are seen to traverse the empty part of the tube. Even the friction of air upon glass is attended by electrical excitation: for Wilson found, that by blowing upon a dry plate of glass with a pair of bellows, it acquired a positive electricity. Whenever bodies change their forms, their electrical states are also altered. Thus, the conversion of water into vapour, and the congelation of melted resins and sulphur are processes in which electricity is also rendered sensible.

When an insulated plate of zinc is brought into contact with one of copper or silver, it is found, after removal, to be positively electrical, and the silver or copper is left in the opposite state.

The most oxidisable metal is always positive, in relation to the least oxidisable metal, which is negative, and the more opposite the metals in these respects the greater the electrical excitation; and if the metals be placed in the following order, each will become positive by the contact of that which precedes it, and negative by the contact of that which follows it; and the greatest effect will result from the contact of the most distant metals.

Platinum.
Gold.
Silver.
Mercury.
Copper.
Iron.
Tin.
Lead.
Zinc.

If the nerve of a recently-killed frog be attached to a silver probe, and a piece of zinc be brought into the contact of the muscular parts of the animal, violent convulsions are produced every time the metals thus connected are made to touch each other. Exactly the same effect is produced by an electric spark, or the discharge of a very small Leyden-phial.

If a piece of zinc be placed upon the tongue, and a piece of silver under it, a peculiar sensation will be perceived every time the two metals are made to touch.

In these cases the chemical properties of the metals are observed to be affected. If a silver and zinc wire be put into a wine glass full of dilute sulphuric acid, the zinc wire will only evolve gas; but upon bringing the two wires in contact with each other, the silver will also copiously produce air bubbles.

If a number of alternations be made of copper or silver leaf, zinc leaf and thin paper, the electricity excited by the contact of the metals will be rendered evident to the common electrometer.

If the same arrangement be made with the paper moistened with brine, or a weak acid, it will be found, on bringing a wire communicating with the last copper plate into contact with the first zinc plate, that a spark is perceptible, and also a slight shock, provided the number of alternations be sufficiently numerous. This is the voltaic apparatus.

Several modes of constructing this apparatus have been adopted, with a view to render it more convenient or active. Sometimes double plates of copper and zinc soldered together, are cemented into wooden troughs in regular order, the intervening cells being filled with water, or saline, or acid solutions.

Another form consists in arranging a row of glasses, containing dilute sulphuric acid, in each of which is placed a wire, or plate of silver, or copper, and one of zinc, not touching each other, but so connected by metallic wires, that the zinc of the first cup may communicate with the copper of the second; the zinc of the second with the copper of the third; and so on throughout the series.

When the poles of the Voltaic apparatus are connected by a steel wire, it requires magnetic properties, and if by a platinum, or other metallic wire, that wire exhibits numerous magnetic poles, which attract and repel the common magnetic needle. This very curious fact was first observed by Professor Oersted, of Copenhagen.

On immersing the wires from the extremes of this apparatus into water, it is found that the fluid suffers decomposition, and that oxygen gas is liberated at the positive wire or pole, and hydrogen gas at the negative pole.

All other substances are decomposed with similar phenomena, the inflammable element being disengaged at the negatively electrical surface; hence it would appear, upon the principle of similarly electrified bodies repelling each other, and dissimilarly electrified bodies attracting each other, that the inherent or natural electrical state of the inflammable substances is positive, for they are attracted by the negative or oppositely electrified pole; while the bodies called supporters of combustion, or acidifying principles, are attracted by the positive pole, and, therefore, may be considered as possessed of the negative power.

When bodies are thus under the influence of electrical decomposition, their usual chemical energies are suspended, and some very curious phenomena are observed.

The most difficult decomposable compounds may be thus resolved into their component parts by the electrical agency; by a weak power the proximate elements are separated, and by a stronger power these are resolved into their ultimate constituents.

All bodies which exert powerful chemical agencies upon each other when freedom of motion is given to their particles, render each other oppositely electrical when acting as masses. Hence Sir H. Davy, the great and successful investigator of this branch of chemical philosophy, has supposed that electrical and chemical phenomena, though in themselves quite distinct, may be dependent upon one and the same power, acting in the former case upon masses of matter, in the other upon its particles.

The power of the Voltaic apparatus to communicate divergence to the electrometer, is most observed when it is well insulated, and filled with pure water; but its power of producing ignition and of giving shocks, and of producing the other effects observed when its poles are connected, are much augmented by the interposition of dilute acids, which act chemically upon one of the plates; here the insulation is interfered with by the production of vapour, but the quantity of electricity is much increased, a circumstance which may, perhaps, be referred to the increase of the positive energy of the most oxidisable metal by the contact of the acid. In experiments made with the great battery of the Royal Institution, it has been found that 120 plates rendered active by a mixture of one part of nitric acid, and three of water, produces effects equal to 480 plates rendered active by one part of nitric acid, and fifteen of water.

In the Voltaic pile, the *intensity* of the electricity increases with the number of alternations, but the *quantity* is increased by extending the surface of the plates. Thus, if a battery, composed of thirty pairs of plates, two inches square, be compared with another battery of thirty pairs of twelve inches square charged in the same way, no difference will be perceived in their effects upon bad or imperfect conductors; their powers of decomposing water and of giving shocks will be similar; but upon good conductors the effects of the large plates will be considerably greater than those of the small: they will ignite and fuse large quantities of platinum wire, and produce a very brilliant spark between charcoal points. The following experiment well illustrates the different effects of quantity and intensity in the Voltaic apparatus.

Immerse the platinum wires connected with the extremity of a charged battery composed of twelve-inch plates into water, and it will be found that the evolution of gas is nearly the same as that occasioned by a similar number of two-inch plates. Apply the moistened fingers to the wires, and the shock will be the same as if there were no connexion by the water. While the circuit exists through the human body and the water, let a wire attached to a thin slip of charcoal be made to connect the poles of the battery, and the charcoal will become vividly ignited. The water and the animal substance discharge the electricity of a surface, probably, not superior to their own surface of contact with the metals; the wires discharge all the residual electricity of the plates; and if a similar experiment be made on plates of an inch square, there will scarcely be any sensation when the hands are made to connect the ends of the battery, a circuit being previously made through water; and no spark, when charcoal is made the medium of connexion, imperfect conductors having been previously applied. These relative effects of quantity and intensity were admirably illustrated by the experiments instituted by Children, who constructed a battery, the plates of which were two feet eight inches wide, and six feet high. They were fastened to a beam, suspended by counterpoises, from the ceiling of his laboratory, so as to be easily immersed into, or withdrawn from the cells of acid. The effects upon metallic wires and perfect conductors were extremely intense; but upon imperfect conductors, such as the human body and water, they were feeble.—*Phil. Trans.* 1815, p. 363.

When the extremes of a battery composed of large plates are united by wires of different metals, it is found that some are more easily ignited than others, a circumstance which has been referred to their conducting powers; thus platinum is more easily ignited than silver, and silver than zinc. If the ignition be supposed to result from the resistance to the passage of electricity, we should say that the zinc conducted better than silver, and the silver than platinum.

An important improvement has been suggested in the construction of the Voltaic apparatus, by Dr. Wollaston, (Annals of Philosophy, Sept. 1815,) by which great increase of *quantity* is obtained, without inconvenient augmentation of the size of the plates; it consists in extending the copper plate, so as to oppose it to every surface of the zinc.

With a single pair of plates, of very small dimensions, constructed upon this principle, Dr. Wollaston succeeded in fusing and igniting a fine platinum wire. This is the most economical and useful form of the Voltaic apparatus; certainly, at least, it is so for all those researches in which there is an occasional demand for quantity as well as intensity of electricity.

The theory of the Voltaic pile is involved in many difficulties. The original source of electricity appears to depend upon the contact of the metals, for we know that a plate of silver, and a plate of zinc, or of any other difficultly and easily oxidisable metals, become negative and positive on contact. The accumulation must be referred to *induction*, which takes place in the electrical column, through the very thin stratum of air, or paper, and through water, when that fluid is interposed between the plates. Accordingly, we observe, that the apparatus is in the condition of the series of conductors, with interposed air, and of the Leyden phials. When the electric column is insulated, the extremities exhibit feeble negative and positive powers, but if either extremity be connected with the ground, the electricity of its poles or extremities is greatly increased, as may be shown by the increased divergence of the leaves of the electrometer which then ensues.

As general changes in the form and constitution of matter are connected with its electrical states, it is obvious that electricity must be continually active in nature. Its effects are exhibited on a magnificent scale in the thunder-storm, which results from the accumulation of electricity in the clouds, as was first experimentally demonstrated by Dr. Franklin, who also first showed the advantage of pointed conductors as safeguards to buildings. In these cases, the conducting rod, or rods, should be of copper, or iron, and from half to three-fourths of an inch diameter. Its upper end should be elevated three or four feet above the highest part of the building, and all the metallic parts of the roof should be connected with the rod, which should be perfectly continuous throughout, and passing down the side of the building, penetrate several feet below its foundation, so as always to be immersed in a moist stratum of soil, or if possible, into water. The leaden water-pipes attached to houses, often might be made to answer the purpose of conductors, especially when thick enough to resist fusion.

During a thunder-storm the safest situation is in the middle of a room, at a distance from the chimney, and standing upon a woollen rug, which is a nonconductor. Blankets and feathers being nonconductors, bed is a place of comparative safety, provided the bell-wires are not too near, which are almost always melted in houses struck by lightning. When out of doors, it is dangerous to take shelter under trees: the safest situation is within some yards of them, and upon the dryest spot that can be selected.

The discharge of electricity in a thunder-storm is sometimes only from cloud to cloud; sometimes from the earth to the clouds; and sometimes from the clouds to the earth; as one or the other may be positive or negative. When aqueous vapour is condensed, the clouds formed are usually more or less electrical; and the earth below them being brought into an opposite state, by induction, a discharge takes place when the clouds approach within a certain distance, constituting lightning; and the indulation of the air, produced by the discharge, is the cause of thunder, which is more or less intense, and of longer or shorter duration, according to the quantity of air acted upon, and the distance of the place, where the report is heard from the point of the discharge. It may not be uninteresting to give a further illustration of this idea. Electrical effects take place in no sensible time. It has been found that a discharge through a circuit of four miles is instantaneous; but sound moves at the rate of about twelve miles a minute. Now, suppose the lightning to pass through a space of some miles, the explosion will be first heard from the point of the air agitated nearest to the spectator; it will gradually come from the more distant parts of the course of electricity, and last of all, will be heard from the remote extremity, and the different degrees of the agitation of the air, and likewise the difference of the distance, will account for the different intensities of the sound, and its apparent reverberations and changes.

In a violent thunder-storm, when the sound instantly succeeds the flash, the persons who witness the circumstance are in some danger; when the interval is a quarter of a minute, they are secure.

A variety of electrical apparatus has been devised to illustrate the operation of conductors for lightning, and the advantage of points over balls; the simplest consists of a model of a house having a conductor with a break in it, in which some inflammable matter should be placed; the lower end of the conductor should be communicated with the exterior of a charged Leyden phial, the knob of which brought over its upper end, will then represent a thunder cloud. If the conductor be pointed, it will be slowly discharged, if surmounted by a ball, there will be an explosion, and the combustibles probably inflamed.

The coruscations of the *Aurora borealis* are also probably electrical, and much resemble flashes of electrical light traversing rarefied air. The water-spout may be referred to the same source, and is probably the result of the operation of a weakly electrical cloud, at an inconsiderable elevation above the sea, brought into an opposite electrical state: and the attraction of the lower part of the cloud, for the surface of the water, may be the immediate cause of this extraordinary phenomenon.

In the *gymnotus*, or *electric* eel, and in the *torpedo*, or *electric ray*, are arrangements given to those remarkable animals for the purpose of defence, which certain forms of the Voltaic apparatus must resemble; for they consist of many alternations of different substances. These electrical organs are much more abundantly supplied with nerves than any other part of the animal, and the too frequent use of them is succeeded by debility and death.

That arrangements of different organic substances are capable of producing electrical effects, has been shown by various experimentalists. If the hind legs of a frog be placed upon a glass plate, and the crural nerve dissected out of one made to communicate with another, it will be found on making occasional contacts with the remaining crural nerve, that the limbs of the animal will be agitated at each contact. These circumstances have induced some physiologists to suppose, that electricity may be concerned in some of the most recondite phenomena of vitality, and Dr. Wollaston, Sir E. Home, and myself, have made some experiments tending to confer probability on this idea.

We have as yet no plausible hypothesis concerning the *cause* of electrical phenomena, though the subject has engaged the attention of the most eminent philosophers of Europe. They have been by some, referred to the presence of a peculiar fluid existing in all matter, and exhibiting itself by the appearances which have been described wherever its equilibrium is disturbed, presenting negative and positive electricity, when deficient, and when redundant. Others have plausibly argued for the presence of two fluids, distinct from each other. Others have considered the effects as referrible to peculiar exertions of the attractive powers of matter, and have regarded the existence of any distinct fluid, or form of matter, to be as unnecessary to the explanation of the phenomena, as it is in the question concerning the cause of gravitation.

When the flame of a candle is placed between a positive and negative surface, it is urged towards the latter; a circumstance which has been explained upon the supposition of a current of electrical matter passing from the positive to the negative pole; indeed, it has been considered as demonstrating the existence of such a current of matter. But if the flame of phosphorus be substituted for that of a candle, it takes an opposite direction; and instead of being attracted towards the negative, it bends to the positive surface. It has been shown that inflammable bodies are always attracted by negative surfaces, and acid bodies, and those in which the supporters of combustion prevail, are attracted by positive surfaces. Hence the flame of the candle throwing off carbon is directed to the negative pole, while that of phosphorus forming acid matter goes to the positive, consistently with the ordinary laws of electro-chemical attraction.

There are other experiments opposed to the idea that electricity is a material substance. If we discharge a Leyden phial through a quire of paper, the perforation is equally burred upon both sides, and not upon the negative side only, as would have been the case if any material body had gone through in that direction. The power seems to have come from the centre of the paper, as if one-half of the quire had been attracted by the positive, and the other by the negative surface.

When a pointed metallic wire is presented towards the conductor of the electrical machine, in a darkened room, a star of light is observed when the conductor is positive, but a brush of light when it is negative; a circumstance which has been referred to the reception of the electric fluid in the one case, and its escape in the other. In the Voltaic discharge, the same appearances are evident upon the charcoal point, rays appearing to diverge from the negative conductor, while upon the positive a spot of bright light is perceptible. But these affections of light can scarcely be considered as indicating the omission or reception of any specific form of matter.

The efficacy of electricity in the cure of several diseases has been supported by many very respectable authorities, especially in paralytic diseases. It considerably augments the circulation of the blood, and excites the action of the absorbents."—*Brande's Chemistry.*

ELECTRO-MAGNETISM. The name given to a class of very interesting phenomena, first observed by Oersted, of Copenhagen, in the winter of 1819-20, and which have since received great illustration from the labours of Ampère, Arago, Sir H. Davy, Wollaston, Faraday, de la Rive, and several other philosophers. The following is a short outline of the fundamental facts.

Let the opposite poles of a voltaic battery be connected by a metallic wire, which may be left of such length as to suffer its being bent or turned in various directions. This is the conjunctive wire of

Oersted. Let us suppose that the rectilinear portion of this wire is extended horizontally in the line of the magnetic meridian. If a freely suspended compass-needle be now introduced, with its centre *under* the conjunctive wire, the needle will instantly deviate from the magnetic meridian; and it will decline towards the *west*, under that part of the conjunctive wire which is nearest the negative electric pole, or the copper end of the voltaic apparatus. The amount of this declination depends on the strength of the electricity, and the sensibility of the needle. Its *maximum* is 90°.

We may change the direction of the conjunctive wire, out of the magnetic meridian, towards the east or the west, provided it remains above the needle, and parallel to its plane, without any change in the above result, except that of its amount. Wires of platinum, gold, silver, brass, and iron, may be equally employed; nor does the effect cease though the electric circuit be partially formed by water. The effect of the conjunctive wire takes place across plates of glass, metal, wood, water, resin, pottery, and stone.

If the conjunctive wire be disposed horizontally *beneath* the needle, the effects are of the same nature as those which occur when it is *above* it; but they operate in an inverse direction; that is to say, the pole of the needle under which is placed the portion of the conjunctive wire which receives the negative electricity of the apparatus, declines in that case towards the *east*.

To remember these results more readily, we may employ the following proposition: *The pole* ABOVE *which the negative electricity enters, declines towards the* WEST: *but if it enters* BENEATH *it, the needle declines towards the* EAST.

If the conjunctive wire (always supposed horizontal) is slowly turned about, so as to form a gradually increasing angle with the magnetic meridian, the declination of the needle increases, if the movement of the wire be towards the line of position of the disturbed needle; it diminishes, on the contrary, if it recede from its position.

When the conjunctive wire is stretched alongside of the needle in the same horizontal plane, it occasions no declination either to the east or west; but it causes it merely to incline in a vertical line, so that the pole adjoining the negative influence of the pile on the wire dips when the wire is on its west side, and rises when it is on the east.

If we stretch the conjunctive wire, either above or beneath the needle, in a plane perpendicular to the magnetic meridian, it remains at rest, unless the wire be very near the pole of the needle; for, in this case, it rises when the entrance takes place by the west part of the wire, and sinks when it takes place by the east part.

When we dispose the conjunctive wire in a vertical line opposite the pole of the needle, and make the upper extremity of the wire receive the electricity of the negative end of the battery, the pole of the needle moves towards the *east;* but if we place the wire opposite a point betwixt the pole and the middle of the needle, it moves to the *west.* The phenomena are presented in an inverse order, when the upper extremity of the conjunctive wire receives the electricity of the positive side of the apparatus.

It appears from the preceding facts, says Oersted, that the electric conflict (action) is not enclosed within the conducting wire, but that it has a pretty extensive sphere of activity round it. We may also conclude from the observations, that this conflict acts by revolution; for without this supposition we could not comprehend how the same portion of the conjunctive wire, which, placed *beneath* the magnetic pole, carries the needle towards the east, when it is placed *above* this pole, should carry it towards the west. But such is the nature of the circular action, that the movements which it produces take place in directions precisely contrary to the two extremities of the same diameter. It appears also, that the circular movement, combined with a progressive movement in the direction of the length of the conjunctive wire, ought to form a kind of action, which operates *spirally* around this wire as an axis. For further information, Faraday's able and original paper, in the Journal of Science, may be consulted; as also Ampère's several ingenious memoirs in the Annales de Chimie et de Physique.

ELECTRO'DES. (From ηλεκτρον, amber.) An epithet for intestinal fæces which shine like amber.

ELECTROMETER. (From ηλεκτρον, and μετρον, a measure.) See *Electricity.*

ELECTROSCOPE. (From ελεκτρον, and σκοπεω, to see.) See *Electricity.*

ELE'CTRUM. Ηλεκτρον. Amber.

ELECTRUM MINERALE. The tincture of metals. It is made of tin and copper, to which some add gold, and double its quantity of martial regulus of antimony melted together; from these there results a metallic mass, to which some chemists have given the name of *electrum minerale.* This mass is powdered and detonated with nitre and charcoal to a kind of scoria; it is powdered again whilst hot, and then digested in spirit of wine, whence a tincture is obtained of a fine red colour.

ELECTUA'RIUM. An electuary. The London Pharmacopœia refers those articles which were formerly called electuaries to confections. See *Confectio.*

ELECTUARIUM ANTIMONII. ℞. Electuarii sennæ, ℥j; guaiaci gummi, hydrargyri cum sulphure, antimonii ppti. sing. ℥ss; syrupi simplicis q. s. misce. Of this electuary from a drachm to about two drachms is given twice a day, in those cutaneous diseases which go under the general name of scorbutic. It is usually accompanied with the decoctions of elm bark or sarsaparilla.

ELECTUARIUM CASSIÆ. See *Confectio cassiæ.*

ELECTUARIUM CATECHU. *Confectio Japonica.* Electuary of catechu, commonly called Japonic confection. Take of mimosa catechu, four ounces; kino three ounces; cinnamon, nutmeg, each one ounce; opium diffused in a sufficient quantity of Spanish white wine one drachm and a half; syrup of red roses boiled to the consistence of honey, two pounds and a quarter. Reduce the solids to powder, and, having mixed them with the opium and syrup, make them into an electuary. A very useful astringent, and perhaps, the most efficacious way of giving the catechu to advantage. Ten scruples of this electuary contain one grain of opium.

ELECTUARIUM CINCHONÆ CUM NATRO. ℞. natri ppti. ʒij; pulveris cinchonæ unc.; mucilaginis gummi arabici q. s. misce. In this composition mucilage is preferred to syrup on account of its covering the taste of the bark much more advantageously. It should, for this purpose, however, be made thin, otherwise it will increase the bulk of the electuary too much.

This remedy will be found an excellent substitute for the burnt sponge, the powers of which as a remedy in scrophula, are known solely to depend on the proportion of natron contained in it. The dose is two drachms, twice or thrice a day.

ELECTUARIUM OPIATUM. See *Confectio opii.*

ELELI'SPHACOS. (From ελελιζω, to distort, and σφακος, sage: so named from the spiral coiling of its leaves and branches.) A species of sage.

ELEMENT. Radical. First principles. A substance which can no further be divided or decomposed by chemical analysis.

E'LEMI. (It is said this is the Ethiopian name.) Gum elemi. The parent plant of this resin is supposed to be an amyris. See *Amyris elemifera.*

ELEN'GI. A tree of Malabar, which is said to possess cordial and carminative properties.

ELEOCHRY'SUM. (From ηλιος, the sun, and χρυσος, gold; so called from its gold-like, or shining yellow appearance.) Goldilocks. See *Gnaphalium stæchas.*

ELEOSELI'NUM. (From ελος, a lake, and σελινον, parsley.) See *Apium.*

ELEPHA'NTIA. (From ελεφας, an elephant; so called from the great enlargement of the body in this disorder.) See *Elephantiasis.*

ELEPHANTIA ARABUM. In Dr. Cullen's Nosology it is synonomous with elephantiasis. The term is, however, occasionally confined to this disease when it affects the feet.

ELEPHANTI'ASIS. (From ελεφας, an elephant: so named from the legs of people affected with this disorder growing scaly, rough, and wonderfully large, at an advanced period, like the legs of an elephant.) *Elephas; Elephantia; Lazari morbus vel malum; Phœniceus morbus.* A disease that attacks the whole body, but mostly affects the feet, which appear somewhat like those of the elephant. It is known by the skin being thick, rough, wrinkly, unctuous, and void of hair, and mostly without the sense of feeling. It is said to be contagious. Cullen makes it a genus of disease in the class *Cachexiæ*, and order *Impetigines.*

Elephantiasis has generally been supposed to arise in consequence of some slight attack of fever, on the cessation of which the morbid matter falls on the leg, and occasions a distention and tumefaction of the limb, which is afterwards overspread with uneven lumps, and deep fissures. By some authors it has been considered as a species of leprosy; but it often subsists for many years without being accompanied with any of the symptoms which characterise that disease.

It sometimes comes on gradually, without much previous indisposition; but more generally, the person is seized with a coldness and shivering, pains in the head, back, and loins, and some degree of nausea. A slight fever then ensues, and a severe pain is felt in one of the inguinal glands, which, after a short time becomes hard, swelled, and inflamed. No suppuration, however, ensues; but a red streak may be observed running down the thigh from the swelled gland to the leg. As the inflammation increases in all the parts, the fever gradually abates, and perhaps, after two or three days' continuance goes off. It, however, returns again at uncertain periods, leaving the leg greatly swelled with varicose turgid veins, the skin rough and rugged, and a thickened membrana cellulosa. Scales appear also on the surface, which do not fall off, but are enlarged by the increasing thickness of the membranes; uneven lumps, with deep fissures, are formed, and the leg and foot become at last of an enormous size.

A person may labour under this disease many years, without finding much alteration in the general health, except during the continuance of the attacks; and perhaps the chief inconvenience he will experience is the enormous bulky leg which he drags about with him. The incumbrance has, indeed, induced many who have laboured under this disease to submit to an amputation; but the operation seldom proves a radical cure, as the other leg frequently becomes affected.

Hilary observes, that he never saw both legs swelled at the same time. Instances where they have alike acquired a frightful and prodigious size, have, however, frequently fallen under the observation of other physicians.

ELEPHANTI'NUM EMPLASTRUM. A plaster described by Oribasius. Celsus describes one of the same name, but very different in qualities.

E'LEPHAS. (Ελεφας, the elephant.)

1. The name of an animal.

2. The name of a disease of the skin. See *Elephantiasis.*

3. Aqua fortis was so called in some old chemical books.

ELE'RSNA. An old term for black lead.

ELE'SMATIS. An old term for burnt lead.

ELE'TTARI PRIMUM. The true amomum. See *Elettaria cardamomum.*

ELETTA'RIA. (From *elettari.*) The name of a new genus of plants formed by Dr. Maton, to which the lesser cardamom is referred. Class, *Monandria;* Order, *Monogynia.*

ELETTARIA CARDAMOMUM. *Cardamomum minus.* Lesser or officinal cardamom. *Amomum repens;* or *le cardamome de la côte de Malabar,* of Sonnerat. *Elettaria cardamomum,* of Maton, in Act. Soc. Lin. The seeds of this plant are imported in their capsules or husks, by which they are preserved, for they soon lose a part of their flavour when freed from this covering. On being chewed, they impart a glowing aromatic warmth, and grateful pungency; they are supposed gently to stimulate the stomach, and prove cordial, carminative, and antispasmodic, but without that irritation and heat which many of the other spicy aromatics are apt to produce. Simple and compound spirituous tinctures are prepared from them, and they are ordered as a spicy ingredient in many of the officinal compositions.

ELEUTHE'RIA. See *Croton cascarilla.*

ELEVA'TIO. (From *elevo,* to lift up.) Elevation. Sublimation.

ELEVA'TOR. (From *elevo,* to lift up.)

1. A muscle is so called, the office of which is to lift up the part to which it is attached.

2. A chirurgical instrument, *elevatorium,* with which surgeons raise any depressed portion of bone, but chiefly those of the cranium.

ELEVATOR LABII INFERIORIS PROPRIUS. See *Levator labii inferioris.*

ELEVATOR LABII SUPERIORIS PROPRIUS. See *Levator labii superioris alæque nasi.*

ELEVATOR LABIORUM. See *Levator anguli oris.*

ELEVATOR NASI ALARUM. See *Levator labii superioris alæque nasi.*

ELEVATOR OCULI. See *Rectus superior oculi.*

ELEVATOR PALPEBRÆ SUPERIORIS. See *Levator palpebræ superioris.*

ELEVATOR SCAPULÆ. See *Levator scapulæ.*

ELEVATO'RIUM. (From *elevo,* to lift up.) An instrument to raise a depression in the skull.

ELI'BANUM. See *Juniperus lycia.*

ELICHRY'SUM. (From ηλιος, the sun, and χρυσος, gold; so called from its gold-like, or shining yellow appearance.) See *Gnaphalium stæchas.*

ELI'DRION. Mastich. A mixture of brass.

ELI'GMA. A linctus.

ELIOSELI'NUM. See *Eleoselinum.*

ELIPTICUS. Eliptic. Applied to leaves.

and receptacles, which are of a somewhat oval form, but broader at each end; as in the leaf of the *Convallaria majalis*, and the receptacle of the *Dorstenia drakenia*.

ELIQUATION. An operation by means of which a more fusible substance is separated from another, which is less fusible. It consists in the application of a degree of heat, sufficient to fuse the former, but not the latter.

ELITHROI′DES. The vaginal coat of the testicle. See *Elythroides* and *Testis*.

ELIXA′TIO. (From *elixo*, to boil.) The act of seething, or boiling.

ELI′XIR. (From *elekser*, an Arabic word, signifying quintessence.) A term formerly applied to many preparations similar to compound tinctures. It is now very little employed.

Elixir of health. Elixir salutis. A term formerly applied to tincture of senna.

ELIXIR PAREGORICUM. See *Tinctura camphoræ composita*.

ELIXIR PROPRIETATIS. A preparation like the compound tincture of aloes.

ELIXIR SACRUM. A tincture of rhubarb and aloes.

ELIXIR SALUTIS. See *Tinctura sennæ*.

ELIXIR STOMACHICUM. See *Tinctura gentianæ composita*.

ELIXIVA′TIO. (From *elixo*, to boil, or from *lixivium*, lye.) The extraction of a fixed salt from vegetables, by an affusion of water. See *Lixiviation*.

ELLAGIC ACID. (*Acidum ellagicum*; so named by Braconnot, by reversing the word *galle*.) The deposit which forms in infusion of nut galls left to itself, is not composed solely of gallic acid and a matter which colours it. It contains besides a little gallate and sulphate of lime, and a new acid, which was pointed out for the first time by Chevreuil in 1815, an acid on which Braconnot made observations in 1818, and which he proposed to call acid *ellagic*, from the word *galle* reversed. Probably this acid does not exist ready formed in nut-galls. It is insoluble; and carrying down with it the greater part of the gallic acid, forms the yellowish crystalline deposit. But boiling water removes the gallic acid from the ellagic; whence the means of separating them from one another. *Ann. de Chim. et de Phys.* ix. 181.

ELLEBORUM. See *Helleborus* and *Veratrum*.

ELM. See *Ulmus*.

Elm-leaved sumach. See *Rhus coriaria*.

ELMI′NTHES. (From ειλεω, to involve, from its contortions.) A worm.

ELO′DES. (From ελος, a swamp.) A term given to a sweating fever, from its great moisture.

ELONGA′TIO. (From *elongo*, to lengthen out.) An imperfect luxation, where the ligament is only lengthened, and the bone not put out of its socket.

ELOY, NICHOLAS FRANCIS JOSEPH, was born at Mons, in 1714, and died in 1788, having practised as a physician with great ability and humanity. He had the honour of attending Prince Charles of Lorraine. He was a man of extensive learning, and, notwithstanding his professional avocations, was author of several publications. The principal of these, an Historical Medical Dictionary, was originally in two octavo volumes; but in 1778, it appeared greatly improved and enlarged in four volumes quarto. An Introduction to Midwifery; a Memoir on Dysentery; Reflections on the Use of Tea; and a Medico-Political Tract on Coffee; were likewise written by this author. The latter work procured him the reward of a superb snuff-box from the estates of Hainault, inscribed "Ex dono Patriæ."

ELUTRIATION. (*Elutriatio*; from *elutrio*, to cleanse.) Washing. It is the pouring a liquor out of one vessel into another, in order to separate the lighter earthy parts, which are carried away while the heavier metallic parts subside to the bottom.

ELU′VIES. (From *eluo*, to wash out.) The effluvium from a swampy place. Also the humour discharged in fluor albus.

ELUXA′TIO. (From *eluxo*, to put out of joint.) A luxation, or dislocation.

ELYMAGRO′STIS. (From ελυμος, the herb panic, and αγρωϛις, wild.) Wild panic.

ELY′MUS. Ελυμος. The herb panic, or panicum of Dioscorides, but now the name of a new genus of grasses, in the Linnæan system.

ELYOT, Sir THOMAS, was born of a good family in Suffolk, about the beginning of the sixteenth century. After studying at Oxford, and improving himself by travelling, he was introduced at court; and Henry VIII. conferred upon him the honour of knighthood, and employed him in several embassies. He distinguished himself in various branches of learning, as well as by patronising learned men; and was generally beloved by his cotemporaries for his virtues and accomplishments. He died in 1546, and was buried in Cambridgeshire, of which he had been sheriff. Among other studies, he was partial to medicine, and made himself master of the ancient authors on that subject, though he never exercised the profession. He published a work about the year 1541, called "The Castell of Health," which was much admired, even by some of the faculty: in this he is a strong advocate for temperance, especially in sexual pleasures. He also notices, that catarrhs were much more common than they had been forty years before; which he ascribes chiefly to free living, and keeping the head too much covered. He also wrote and translated several other works, but not on medical subjects.

ELYTROCE′LE. (From ελυτρον, the vagina, and κηλη, a tumour.) A hernia in the vagina. See *Hernia vaginalis*.

ELYTROI′DES. (*Elytroides*; from ελυτρον, a sheath, and ειδος, form.) Like a sheath. The tunica vaginalis is so called by some writers, because it includes the testis like a sheath.

ELY′TRON. (From ελυω, to involve.) The vagina. A sheath. The membranes which involve the spinal marrow are called ελυτρα.

EMACIATION. See *Atrophia* and *Marasmus*.

EMARGINA′TIO. (From *emargino*, to cleanse the edges.) The cleansing of the edges of wounds from scurf and filth.

EMARGINATUS. Emarginate, nicked, that is, having a small acute notch at the summit; as the leaf of the bladder senna, *Colutea arborescens*, the petals of the *Allium roseum*, and *Agrostema flos jovis*.

EMASCULA′TUS. (From *emasculo*, to render impotent.) Having the testicles in the belly, and not fallen into the scrotum.

EMBA′MMA. (From εμβαπτω, to emerge in.) A medicated pickle to dip the food in.

E′MBOLE. (From εμβαλλω, to put in.) The setting of a dislocated bone.

E′MBOLUM. (From εμβαλλω, to cast out; so named because it ejects the semen.) The penis.

EMBRE′GMA. (From εμβρεχω, to make wet.) A fluid application to any part of the body.

EMBROCA′TIO. (From εμβρεχω, to moisten or soak in.) *Embroche.* An embrocation. A fluid application to rub any part of the body with. Many use the term, however, as synonymous with liniment. The following embrocations are in general use.

EMBROCATIO ALUMINIS. ℞. Aluminis ʒij. Aceti, spiritus vinosi tenuïoris, sing. ℔ss. For chilblains and diseased joints.

EMBROCATIO AMMONIÆ. ℞. Embrocationis ammoniæ acetatis ℥ij. Aquæ ammoniæ puræ ʒij. For sprains and bruises.

EMBROCATIO AMMONIÆ ACETATIS. ℞. Aquæ ammoniæ acetatæ. Solutionis saponis sing. ℥j M. For bruises with inflammation.

EMBROCATIO AMMONIÆ ACETATIS CAMPHORATA. ℞. Solutionis saponis cum camphora, aquæ ammoniæ acetatæ sing. ℥j. Aquæ ammoniæ puræ ℥ss. For sprains and bruises. It is also frequently applied to disperse chilblains which have not suppurated. It is said to be the same as Steer's opodeldoc.

EMBROCATIO CANTHARIDIS CUM CAMPHORA. ℞. Tinct. cantharidis. Spiritus camphoræ sing. ℥j M. This may be used in any case in which the object is to stimulate the skin. The absorption of cantharides, however, may bring on a stranguary.

E'MBROCHE. See *Embrocatio.*

E'MBRYO. (From εμβρυω, to bud forth.) 1. The germ of a plant; called by Linnæus the *corculum.* See *Corculum* and *Cotyledon.*

2. The *fœtus in utero* is so called before the fifth month of pregnancy, because its growth resembles that of the budding of a plant.

EMBRYOTHLA'STES. (From εμβρυον, the fœtus, and θλαω, to break.) *Embryorectes.* A crotchet or instrument for breaking the bones of a dead fœtus to promote its delivery.

EMBRYO'TOMY. (*Embryotomia;* from εμβρυον, a fœtus, and τεμνω, to cut.) The separating of any part of the fœtus whilst *in utero,* to extract it.

EMBRYU'LCUS. (From εμβρυον, a fœtus, and ελκω, to draw.) A blunt hook or forceps, for drawing the child from the womb.

EMERALD. A beautiful genus of minerals, which contains two species.

1. *The prismatic emerald,* Euclase of Haüy. This is of a green and sky-blue colour, and is found in Peru and Brazil.

2. *Rhomboidal emerald,* of which there are two sub species, the precious emerald and the beryl. The first is well-known by its emerald green colour. The most beautiful emeralds come from Peru. As a gem, it is valued next to ruby.

EMERSUS. (From *emergo,* to rise up or appear out of the water.) Raised above the water, as the upper leaves accompanying the flowers of the *Meriophyllum verticillatum,* while its lower ones are *demersa.*

E'MERUS. Scorpion senna. A laxative.

EMERY. A sub-species of rhomboidal corundum, found in quantities in the isle of Naxor, and at Smyrna. Its fine powder, which is used for polishing hard minerals and metals, is made by trituration and elutriation.

EMESIA. (From εμεω, to vomit.) *Emesma; Emesis.* The act of vomiting. Medicines which cause vomiting.

EME'TIC. (*Emeticus;* from εμεω, to vomit.) That which is capable of exciting vomiting, independently of any effect arising from the mere quantity of matter introduced into the stomach, or of any nauseous taste or flavour.

The susceptibility of vomiting is very different in different individuals, and is often considerably varied by disease.

Emetics are employed in many diseases.

When any morbid affection depends upon, or is connected with, over-distention of the stomach, or the presence of acrid, indigestible matters, vomiting gives speedy relief. Hence its utility in impaired appetite, acidity in the stomach, in intoxication, and where poisons have been swallowed.

From the pressure of the abdominal viscera in vomiting, emetics have been considered as serviceable in jaundice, arising from biliary calculi obstructing the ducts.

The expectorant power of emetics, and their utility in catarrh and phthisis, have been ascribed to a similar pressure extended to the thoracic viscera.

In the different varieties of febrile affections, much advantage is derived from exciting vomiting, especially in the very commencement of the disease. In high inflammatory fever it is considered as dangerous, and in the advanced stage of typhus it is prejudicial.

Emetics given in such doses, as only to excite nausea, have been found useful in restraining hæmorrhage.

Different species of dropsy have been cured by vomiting, from its having excited absorption. To the same effect, perhaps, is owing the dispersion of swelled testicle, bubo, and other swellings, which has occasionally resulted from this operation.

The operation of vomiting is dangerous, or hurtful, in the following cases: where there is determination of the blood to the head, especially in plethoric habits; in visceral inflammation; in the advanced stage of pregnancy; in hernia and prolapsus uteri; and wherever there exists extreme general debility. The frequent use of emetics weakens the tone of the stomach. An emetic should always be administered in the fluid form. Its operation may be promoted by drinking any tepid diluent, or bitter infusion.

The individual emetics may be arranged under two heads, those derived from the vegetable, and those from the mineral kingdom. From the vegetable kingdom are numbered ipecacuanha, scilla maritima, anthemis nobilis, sinapis alba, asarum Europæum, nicotiana tabacum. From the mineral kingdom, antimony, the sulphates of zinc and copper, and the subacetate of copper. To these may be added ammonia and its hydro-sulphuret.

EMETIN. *Emetine.* Digest ipecacuan root, first in æther and then in alkohol. Evaporate the alkoholic infusion to dryness, redissolve in water, and drop in acetate of lead. Wash the precipitate, and then diffusing it in water, decompose by a current of sulphuretted hydrogen gas. Sulphuret of lead falls to the bottom, and the emetin remains in solution. By evaporating the water, this substance is obtained pure.

Emetin forms transparent brownish-red scales. It has no smell, but a bitter acrid taste. At a heat somewhat above that of boiling water, it is resolved into carbonic acid, oil, and vinegar. It affords no ammonia. It is soluble both in water and alkohol, but not in æther; and uncrystallisable. It is precipitated by protonitrate of mercury and corrosive sublimate, but not by tartar emetic. Half a grain of emetin acts as a powerful emetic, followed by sleep; six grains vomit violently, and produce stupor and death. The lungs and intestines are inflamed."—*Pelletier* and *Magendie.*

Emetine. See *Emetin.*

EMETOCATHA'RTICUS. (From εμεω, to vomit, and καθαιρω, to purge.) Purging both by vomit and stool.

EMINE′NTIÆ QUADRIGEMINÆ. See *Tuburcula quadrigemina.*

EMMENAGOGUE. (*Emmenagogus*; from εμμηνια, the menses, and αγω, to move.) Whatever possesses the power of promoting that monthly discharge by the uterus, which, from a law of the animal economy, should take place in certain conditions of the female system. The articles belonging to this class may be referred to four orders:—

1. *Stimulating emmenagogues*, as *hydrargyrine* and *antimonial preparations*, which are principally adapted for the young, and those with peculiar insensibility of the uterus.

2. *Irritating emmenagogues*, as *aloes, savine*, and *Spanish flies*: these are to be preferred in torpid and chlorotic habits.

3. *Tonic emmenagogues*, as *ferruginous preparations, cold bath*, and *exercise*, which are advantageously selected for the lax and phlegmatic.

4. *Antispasmodic emmenagogues*, as *asafœtida, castor*, and *pediluvia*: the constitutions to which these are more especially suited are the delicate, the weak, and the irritable.

EMME′NIA. (From εν, in, and μην, a month.) The menstrual flux.

EMO′LLIENT. (*Emolliens*; from *emollio*, to soften.) Possessing the power of relaxing the living and animal fibre, without producing that effect from any mechanical action. The different articles belonging to this class of medicines may be comprehended under the following orders:—

1. *Humectant emollients*, as *warm water*, and *tepid vapours*, which are fitted for the robust and those in the prime of life.

2. *Relaxing emollients*, as *althæa, malva*, &c. These may be employed in all constitutions, while at the same time they do not claim a preference to others from any particular habit of body.

3. *Lubricating emollients*, as *bland oils, fat*, and *lard*. The same observation will hold of this order as was made of the last-mentioned.

4. *Atonic emollients*, as *opium* and *pediluvia*. These are applicable to any constitution, but are to be preferred in habits where the effects of this class are required over the system in general.

EMPATHEMA. (Ἐμπαθης; from παθημα, *passio, affectio.*) Ungovernable passion. A genus of disease in Good's Nosology. Class, *Neurotica*; Order, *Phrenica*.

It has three species, *Empathema eutonicum, atonicum, insane*, and innumerable varieties.

EMPEI′RIA. (From εν, and ϖειρω, to endeavour.) Professional experience.

EMPHERO′MENUS. (From εμφερω, to bear.) Urine, or other substances which have a sediment.

EMPHLYSIS. (From εμ, in, and φλυσις, a vesicular tumour or eruption.) The name of a genus, *ichorous exanthem*, of Good's Nosology, which includes six species: *Emphlysis miliaria*; *Aphtha*; *Vaccinia*; *Varicella*; *Pemphigus*; *Erysipelas*.

EMPHRA′CTICA. (From εμφραττω, to obstruct.) Medicines which, applied to the skin, shut up the pores.

EMPHYMA. This term, applied by Good to a genus of disease, Class, *Eccritica*; Order, *Mesotica*, of his arrangement, imports (in contradiction to *Phyma*, which, in his system, is limited to cutaneous tumours, accompanied with inflammation,) a tumour originating below the integuments, and unaccompanied with inflammation, at least in its commencement. It embraces three species, viz. *Emphyma sarcoma*; *Encystis*; *Exotosis*.

EMPHYSE′MA. (*Emphysema, atis.* n.; from εμφυσαω, to inflate.) See *Pneumatosis*.

EMPIRIC. (*Empiricus*. Εμπειρικος; from εν, in, and ϖειρα, experience.) One who practises the healing art upon experience, and not theory. This is the true meaning of the word empiric; but it is now applied, in a very opposite sense, to those who deviate from the line of conduct pursued by scientific and regular practitioners, and vend nostrums, or sound their own praise in the public papers.

EMPLA′STICA. (From εμπλασσω, to obstruct.) Medicines which, spread upon the skin, stop the pores.

EMPLA′STRUM. (*Emplastrum*, *i.* n.; from εμπλασσω, to spread upon.) A plaster. Plasters are composed of unctuous substances, united either to powders or metallic oxides, &c. They ought to be of such a consistence as not to stick to the fingers when cold, but to become soft, so as to be spread out in a moderate degree of heat, and in that of the human body, to continue tenacious enough to adhere to the skin. They owe their consistence either to metallic oxides, especially those of lead, or to wax, resin, &c. They are usually kept in rolls wrapped in paper, and spread when wanted for use, upon thin leather; if the plaster be not of itself sufficiently adhesive, it is to be surrounded at its margin by a boundary of resin plaster.

EMPLASTRUM AMMONIACI. Take of purified ammoniacum, five ounces; acetic acid, half a pint. Dissolve the ammoniacum in the acid, then evaporate the liquor in an iron vessel, by means of a water-bath, constantly stirring it, until it acquires a proper consistence. This plaster is now first introduced into the London Pharmacopœia; it adheres well to the skin, without irritating it, and without producing inconvenience by its smell.

EMPLASTRUM AMMONIACI CUM HYDRARGYRO. Take of purified ammoniacum, a pound; purified mercury, three ounces; sulphuretted oil, a fluid drachm. Rub the mercury with the sulphurated oil, until the globules disappear; then add by degrees the ammoniacum, previously melted, and mix the whole together. This composition is said to possess resolvent virtues; and the plaster is recommended with this view to be applied to nodes, tophs, indurated glands, and tumours.

EMPLASTRUM ASAFŒTIDÆ. *Emplastrum antihystericum.* Plaster of asafœtida. Take of plaster of semi-vitrified oxide of lead, asafœtida, each two parts: galbanum, yellow wax, each one part. This plaster is said to possess anodyne and antispasmodic virtues. It is, therefore, occasionally directed to be applied to the umbilical region in hysterical cases.

EMPLASTRUM CANTHARIDIS. Blistering-fly plaster. *Emplastrum vesicatorium.* Take of blistering flies, in very fine powder, a pound; wax plaster, a pound and a half; prepared fat, a pound. Having melted the plaster and fat together, and removed them from the fire, a little before they become solid sprinkle in the blistering flies, and mix the whole together. See *Blister* and *Cantharis*.

EMPLASTRUM CERÆ. Wax plaster. *Emplastrum attrahens.* Take of yellow wax, prepared suet, of each three pounds; yellow resin, a pound. Melt them together and strain. This is a gently-drawing preparation, calculated to promote a moderate discharge from the blistered surface, with which intention it is mostly used. Where the stronger preparations irritate, this will be found in general to agree.

EMPLASTRUM CUMINI. Cumin plaster. Take of cumin-seeds, caraway-seeds, bayberries, of each three ounces; dried pitch, three pounds; yellow wax, three ounces. Having melted the dried pitch and wax together, add the remaining articles previously powdered, and mix. A warm stomachic plaster, which, when applied to the stomach, expels flatulency. To indolent scrofulous tumours, where the object is to promote suppuration, this is an efficacious plaster.

EMPLASTRUM GALBANI COMPOSITUM. Compound Galbanum plaster, formerly called *emplastrum lithargyri compositum* and *diachylon magnum cum gummi.* Take of galbanum gum resin purified, eight ounces; lead plaster, three pounds; common turpentine, ten drachms; resin of the spruce fir, three ounces. Having melted the galbanum gum resin with the turpentine, mix in first the powdered resin of the spruce fir, and then the lead plaster, previously melted by a slow fire, and mix the whole. This plaster is used as a warm digestive and suppurative, calculated to promote maturation of indolent or scirrhous tumours, and to allay the pains of sciatica, arthrodynia, &c.

EMPLASTRUM HYDRARGYRI. Mercurial plaster. *Emplastrum lithargyri cum hydrargyro.* Take of purified mercury, three ounces; sulphurated oil, a fluid drachm; lead plaster, a pound. Rub the mercury with the sulphurated oil, until the globules disappear; then add by degrees the lead plaster, melted, and mix the whole.

EMPLASTRUM LADANI COMPOSITUM. Take of soft labdanum, three ounces; of frankincense, one ounce; cinnamon and expressed oil of mace, each half an ounce; essential oil of mint, one drachm; add to the frankincense, melted first, the labdanum a little heated, till it becomes soft, and then the oil of mace; afterwards mix in the cinnamon with the oil of mint, and beat them together into a mass, in a warm mortar, and keep it in a vessel well closed. This may be used with the same intentions as the cumin-plaster, to which it is in no way superior, though composed of more expensive materials. Formerly, it was considered as a very elegant stomach plaster, but is now disused.

EMPLASTRUM LITHARGYRI. See *Emplastrum plumbi.*

EMPLASTRUM LITHARGYRI COMPOSITUM. See *Emplastrum Galbani compositum.*

EMPLASTRUM LITHARGYRI CUM RESINA. See *Emplastrum resinæ.*

EMPLASTRUM LYTTÆ. See *Emplastrum cantharidis.*

EMPLASTRUM OPII. Plaster of opium. Take of hard opium, powdered, half an ounce; resin of the spruce fir, powdered, three ounces; lead plaster, a pound. Having melted the plaster, mix in the resin of the spruce fir, and opium, and mix the whole. Opium is said to produce somewhat, though in a smaller degree, its specific effect when applied externally.

EMPLASTRUM PICIS COMPOSITUM. Compound pitch plaster. *Emplastrum picis Burgundicæ.* Take of dried pitch, two pounds; resin of spruce fir, a pound; yellow resin, yellow wax, of each four ounces; expressed oil of nutmegs, an ounce. Having melted together the pitch, resin, and wax, add first the resin of the spruce fir, then the oil of nutmegs, and mix the whole together. From the slight degree of redness this stimulating application produces, it is adapted to gently irritate the skin, and thus relieve rheumatic pains. Applied to the temples it is sometimes of use in pains of the head.

EMPLASTRUM PLUMBI. Lead plaster. *Emplastrum lithargyri; Emplastrum commune; Diachylon simplex.* Take of semi-vitreous oxide of lead, in very fine powder, five pounds; olive oil, a gallon; water, two pints. Boil them with a slow fire, constantly stirring until the oil and litharge unite, so as to form a plaster. Excoriations of the skin, slight burns, and the like, may be covered with this plaster: but it is in more general use, as a defensive, where the skin becomes red from lying a long time on the part. This plaster is also of great importance, as forming the basis, by addition to which many other plasters are prepared.

EMPLASTRUM RESINÆ. Resin plaster. *Emplastrum adhæsivum; Emplastrum lithargyri cum resina.* Take of yellow resin, half a pound; lead plaster, three pounds. Having melted the lead plaster over a slow fire, add the resin in powder, and mix. The adhesive, or sticking plaster, is chiefly used for keeping on other dressings, and for retaining the edges of recent wounds together.

EMPLASTRUM SAPONIS. Soap plaster. Take of hard soap sliced, half a pound; lead plaster, three pounds. Having melted the plaster, mix in the soap; then boil it down to a proper consistence. Discutient properties are attributed to this elegant plaster, with which view, it is applied to lymphatic and other indolent tumours. It forms an admirable defensive and soft application, spread on linen, to surround a fractured limb.

EMPLASTRUM THURIS COMPOSITUM. Compound frankincense plaster. Take of frankincense, half a pound; dragon's blood, three ounces; litharge plaster, two pounds. To the melted lead plaster, add the rest powdered. This plaster is said to possess strengthening, as well as adhesive powers. By keeping the skin firm, it may give tone to the relaxed muscles it surrounds, but cannot, in any way, impart more strength than the common adhesive plaster.

EMPNEUMATO'SIS. (From εν, in, and ϖνεω, to blow.) An inflation of the stomach, or any other viscus.

EMPO'RIUM. (From εμπορεω, to negotiate.) A mart. The brain is so called, as being the place where all rational and sensative transactions are collected.

EMPRESMA. Good revives this term (used in its simple form both by Hippocrates and Galen, to express internal inflammation,) to designate a genus of disease in his Class, *Hæmatica;* Order, *Phlogotica.* Visceral inflammation. It embraces inflammation of all the viscera: hence *Empresma cephalitis; otitis; parotitis; paristhmitis; laryngitis; bronchitis; pneumonitis; pleuritis; carditis; peritonitis; gastritis; enteritis; hepatitis; splenitis; nephritis; cystitis; hysteritis; orchitis.*

E'MPRION. (From εν, and ϖριων, a saw.) Serrated. Formerly applied to a pulse, in which the artery at different times is unequally distended.

EMPROSTHO'TONOS. (From εμπροσθεν, before, or forwards, and τεινω, to draw.) A clonic spasm of several muscles, so as to keep the body in a fixed position and bent forward. Cullen considers it as a species of tetanus. See *Tetanus.*

E'MPTYSIS. (From εμπτυω, to spit out.) A discharge of blood from the mouth.

EMPYE'MA. (From εν, within, and ϖυον, pus.) A collection of pus in the cavity of the thorax. It is one of the terminations of pleuritis. There is reason for believing that matter is contained in the cavity of the chest, when, after a pleurisy, or inflammation in the thorax, the patient has a difficulty of breathing, particularly on lying on the side opposite the affected one; and when an œdematous swelling is externally perceptible.

EMPYE'MATA. (From εν, and πυον, pus.) Suppurating medicines.

EMPYESIS. (From εμπυοω, or εμπυεω, *suppuro.*) Good has given this term (found in the fifth book of Hippocrates's aphorisms,) to a genus of disease, class, *Hæmatica;* order, *Exanthematica,* characterised by phlegmonous pimples, which gradually fill with a purulent fluid. It has only one species small-pox—*Empyesis variola.*

Empyreal air. Scheele gave this name to oxygen gas.

EMPYREU'MA. (From εμπυρευω, to kindle, from πυρ, fire.) A peculiar and offensive smell that distilled waters and other substances receive from being exposed to heat in closed vessels, or when burned under circumstances which prevent the accession of air to a considerable part of the mass.

EMPYREUMA'TIC. (*Empyreumaticus;* from εμπυρευω, to kindle.) Smelling as it were burnt; thus empyreumatic oils are those distilled with a great heat, and impregnated with a smell of the fire.

EMU'LGENT. (*Emulgens;* from *emulgeo,* to melt out; applied to the artery and vein which go from the aorta and vena cava to the kidneys, because the ancients supposed they strained, and, as it were, milked the serum through the kidneys.) The vessels of the kidneys are so termed. The emulgent artery is a branch of the aorta. The emulgent vein evacuates its blood into the ascending cava.

EMU'LSIO. (*Emulsio, onis.* f.; from *emulgeo,* to milk.) An emulsion. A soft and somewhat oily medicine resembling milk. An imperfect combination of oil and water, by the intervention of some other substance capable of combining with both these substances.

Emulsio acaciæ. This is made in the same manner as the almond emulsion, only adding while beating the almonds, two ounces of gum arabic. This cooling and demulcent emulsion, ordered in the Edinburgh Pharmacopœia, may be drank ad libitum to mitigate ardor urinæ, whether from the venereal virus or any other cause. In difficult and painful micturition and strangury, it is of infinite service.

Emulsio amygdalæ. Almond emulsion. Take of almonds, one ounce; water, two pounds and a half. Beat the blanched almonds in a stone mortar, gradually pouring on them the water; then strain off the liquor. It possesses cooling and demulcent properties.

Emulsio camphorata. Take of camphor, one scruple; sweet almonds, blanched, two drachms; double refined sugar, one drachm; water, six ounces. This is to be made in the same manner as the common emulsion. It is calculated for the stomachs of those who can only bear small quantities of camphire.

EMULSION. See *Emulsio.*

Emulsion, almond. See *Emulsio amygdalæ.*

Emulsion, Arabic. See *Emulsio acaciæ.*

Emulsion of asafœtida. See *Mistura asafœtidæ.*

Emulsion, camphorated. See *Emulsio camphorata.*

Emulsion of gum-ammoniac. See *Mistura ammoniaci.*

EMU'NCTORY. (*Emunctorium;* from *emungo,* to drain off.) The excretory ducts of the body are so termed; thus the exhaling arteries of the skin constitute the great emunctory of the body.

Enæ'ma. (From εν, and αιμα, blood.) *Enæmos.* So Hippocrates and Galen call such topical medicines as are appropriated to bleeding wounds.

Enæore'ma. (From εν, and αιωρεω, to lift up.) The pendulous substance which floats in the middle of the urine.

ENA'MEL. See *Teeth.*

ENANTHE'SIS. 1. (From εν, *in, intra,* and ανθεω, *floreo;* efflorescence from within, or from internal affection.) A genus of disease, Class, *Hæmatica;* Order, *Exanthematica,* in Good's Nosology. Rash exanthem. It comprehends three species: viz. *Enanthesis rosalia; rubeola; urticaria.*

2. (From εν, and ανταω, to meet.) The near approach of ascending and descending vessels.

ENARTHRO'SIS. (From εν, in, and αρθρον, a joint.) The ball and socket-joint. A species of diarthrosis, or moveable connection of bones, in which the round head of one is received into the deeper cavity of another, so as to admit of motion in every direction; as the head of the os femoris with the acetabulum of the os innominatum. See *Articulation.*

ENCA'NTHIS. (From εν, and κανθος, the angle of the eye.) A disease of the caruncula lachrymalis, of which there are two species. *Encanthis benigna,* and *Encanthis maligna seu inveterata.* The encanthis, at its commencement, is nothing more than a small, soft, red, and sometimes rather livid excrescence, which grows from the caruncula lachrymalis, and at the same time from the neighbouring semilunar fold of the conjunctiva. This excresence on its first appearance is commonly granulated, like a mulberry, or is of a ragged and fringed structure. Afterwards, when it has acquired a certain size, one part of it represents a granulated tumour, while the rest appears like a smooth, whitish, or ash-coloured substance, streaked with varicose vessels, sometimes advancing as far over the conjunctiva, covering the side of the eye next to the nose, as where the cornea and sclerotica unite.

The encanthis keeps up a chronic ophthalmy, impedes the action of the eyelids, and prevents, in particular, the complete closure of the eye. Besides, partly by compressing and partly by displacing the orifices of the puncta lachrymalia, it obstructs the free passage of the tears into the nose. The inveterate encanthis is ordinarily of a very considerable magnitude; its roots extend beyond the caruncula lachrymalis and semilunar fold to the membraneous lining of one or both eyelids. The patient experiences very serious inconvenience from its origin and interposition between the commissure of the eyelids, which it necessarily keeps asunder on the side towards the nose. Sometimes the disease assumes a cancerous malignancy. This character is evinced by the dull red, and, as it were, leaden colour of the excrescence; by its exceeding hardness, and the lancinating pains which occur in it, and extend to the forehead, the whole eye-ball and the temple, especially when the tumour has been, though slightly, touched. It is also shown, by the propensity of the excrescence to bleed, by the partial ulcerations on its surface, which emit a fungous substance, and a thin and exceedingly acrid discharge.

ENCATALE'PSIS. (From εν, and καταλαμβανω, to seize.) A catalepsy.

ENCATHI′SMA. (From εν, and καθιζω, to sit in.) A semicupium, or bath for half the body.

ENCAU′MA. (From εν, in, and καιω, to burn.) A burn. See *Burn*.

ENCAU′SIS. (From εν, and καιω, to burn.) A burn. See *Burn*.

ENCEPHALOCE′LE. (From εγκεφαλον, the brain, and κηλη, a tumour.) A rupture of the brain.

ENCE′PHALON. (From εν, in, and κεφαλη, the head.) *Encephalum*. By some writers the cerebrum only is so called; and others express by this term the contents of the cranium.

ENCE′RIS. (From εν, and κηρος, wax.) A roll of wax for making plasters.

ENCERO′SIS. (From εν, and κηροω, to wax.) The covering of a plaster with wax.

ENCHARA′XIS. (From εν, and χαρασσω, to scarify.) A scarification.

ENCHEIRE′SIS. (From εν, and χειρ, the hand.) *Encheiria*. Galen uses this word as a part of the title to one of his works, which treats of dissection. The word imports the manual treatment of any subject.

ENCHEI′RIA. See *Encheiresis*.

ENCHILO′MA. See *Enchyloma*.

ENCHO′NDRUS. (From εν, and χονδρος, a cartilage.) A cartilage.

ENCHRIS′TA. (From εγχριω, to anoint.) Ointments.

ENCHYLO′MA. (From εν, and χυλος, juice.) An inspissated juice. An elixir, according to Lemery.

E′NCHYMA. (From εν, and χεω, to infuse.) *Enchysis*. 1. An infusion.

2. A sanguineous plethora.

ENCHY′MATA. (From εγχυω, to infuse.) Injections for the eyes and ears.

ENCHYMO′MA. (From εν, and χυω, to pour in.) In the writings of the ancient physicians, it is a word by which they express that sudden effusion of blood into the cutaneous vessels, which arises from joy, anger, or shame; and in the last instance is what we usually call blushing.

ENCHYMO′SIS. Εγχυμωσις. 1. Blushing.

2. An extravasation of blood, which makes the part appear livid.

E′NCHYSIS. See *Enchyma*.

ENCLY′SMA. (From εν, and κλυζω, to cleanse out.) A clyster.

ENCŒ′LIA. (From εν, within, and κοιλια, the belly.) The abdominal viscera.

ENCOLPI′SMUS. (From εγκολπεω, to insinuate.) An uterine injection.

ENCRA′NIUM. (From εν, within, and κρανιον, the skull.) The cerebrum and the whole contents of the skull.

ENCRASI′CHOLUS. (From εν, in, κερας, the head, and χολη, bile; because it is said to have the gall in its head.) The anchovy. See *Clupea*.

E′NCRIS. Εγκρις. A cake of meal, oil, and honey.

E′NCYMON. (From εν, and κυω, to conceive.) Pregnancy.

E′NCYSIS. (From εν, and κυω, to bring forth.) Parturition.

ENCY′STED. *Saccatus*. A term applied to those tumours which consist of a fluid or other matter, enclosed in a sac or cyst.

ENCY′STIS. (From εν, in, and κυϛις, a bag.) An encysted tumour.

ENDE′MIC. (*Endemicus*, sc. *morbus*; from εν, in, and δημος, people.) A disease is so termed that is peculiar to a certain class of persons, or country: thus struma is endemial to the inhabitants of Derbyshire and the Alps; scurvy to seafaring people; and the plica polonica is met with in Poland.

E′NDESIS. (From εν, and δεω, to tie up.) A ligature. A bandage.

ENDIVE. See *Cichorium*.

ENDI′VIA. (*Quasi eundo via, quia passim nascitur*; named from the quickness of its growth.) See *Cichorium*.

E′NDOSIS. (From εν, and διδωμι, to give.) A remission, disorder.

ENECIA. (From Ηνεκης, continued.) A genus of disease in Good's Nosology. Class, *Hæmatica*; Order, *Pyretica*; continued fever. It comprehends three species, *Enecia cauma*; *typhus*; *synochus*.

ENELLA′GMENUS. (From εναλλαττω, to interchange.) An epithet applied to the union of the joints of the vertebræ.

E′NEMA. (*Enema matis*. neut.; from ενιημι, to inject.) A clyster. A well-known form of conveying both nourishment and medicine to the system, under certain morbid circumstances. The former takes place where obstruction of the passage to the stomach is so great as to render access to that organ impossible, such as occurs in lock-jaw, diseased œsophagus, &c. By these means the body can be supported for a few weeks, while an attempt is made at effecting a cure. It is composed, in such cases, of animal broths, gruels made of farinaceous seeds, mucilages, &c. As a form of medicine, clysters are no less useful; and according to the intention with which they are prescribed, they are either of an emollient, anodyne, or purgative nature. The following forms are in general use.

ENEMA ANODYNUM. Take of starch jelly, half a pint; tincture of opium, forty to sixty drops. Mix. The whole to be injected by means of a clyster-syringe, in cases of dysentery or violent purging, and pain in the bowels.

ENEMA ANTISPASMODICUM. Take of tincture of asafœtida, half an ounce; tincture of opium, forty drops, gruel, half a pint. Mix. For spasmodic affections of the bowels.

ENEMA LAXATIVUM. Take of sulphate of magnesia, two ounces; dissolve in three-quarters of a pint of warm gruel, or broth, with an ounce of fresh butter, or sweet oil.

ENEMA NICOTIANÆ. Take of the infusion of tobacco from a half to a whole pint. Employed in cases of strangulated hernia.

ENEMA NUTRIENS. Take of strong beef tea, twelve ounces; thicken with hartshorn shavings, or arrow-root.

ENEMA TEREBINTHINÆ. Take of common turpentine, half an ounce; the yolk of one egg, and half a pint of gruel. The turpentine being first incorporated with the egg, add to them the gruel. This clyster is generally used, and with great good effect, in violent fits of the stone.

ENEREI′SIS. (From ενερειδω, to adhere to a compression.) A tight ligature.

E′NERGY. (*Energia*; from ενεργεω, to act.) The degree of force exercised by any power; thus, nervous energy, muscular energy, &c.

ENERVATING. The act of destroying the force, use, or office of the nerves, either by cutting them, or breaking them by violence or abuse of the non-naturals.

ENEURE′SIS. See *Enuresis*.

ENERVIS. Ribless: applied to leaves which are without lines or ribs.

ENGALA′CTUM. (From εν, and γαλα, milk; so called because it is eaten by nurses to increase their milk.) The herb saltwort. See *Salsola*.

ENGASTRIMY′THUS. (From εν, in, γαϛηρ, the belly, and μυθεομαι, to discourse.) A ventriloquist; one who appears to speak from his belly.

ENGISO′MA. (From εγγιζω, to approach.)

1. An instrument for making the parts of a broken clavicle meet.

2. A fracture of the cranium.

English Mercury. See *Mercurialis.*

Englotto-gastor. (From εν, γλωττη, the tongue, and γαϛηρ, the belly.) A ventriloquist.

ENGOMPHO'SIS. (From εν, and γομφος, a nail.) That species of articulation which resembles a nail driven into wood, as a tooth in its socket.

Engo'nios. (From εν, and γωνια, an angle.) The flexure, or angle made by the bending of a joint.

Eni'xum paracelsi. The caput mortuum of the distillation of nitric acid, which is a supersulphate of potassa.

ENNEANDRIA. (From εννεα, nine, and ἀνηρ, a man.) The name of a class of plants in the sexual system, containing such as have hermaphrodite flowers with nine stamina.

Enneapha'rmacum. (From εννεα, nine, and φαρμακον, a medicine.) A medicine composed of nine simple ingredients.

ENNEAPHY'LLUM. (From εννεα, nine, and φυλλον, a leaf; because its flower consists of nine leaves.) A name for Helleboraster, or bear's-foot.

ENODIS. Without knots: applied to stems of plants, as *Culmus enodis;* that is, a smooth culm, as in our common rushes.

Enry'thmus. (From εν, and ρυθμος, number.) A pulse in some respect regular.

ENS. This word denoted in ancient chemistry the most efficacious part of any natural mixed body, whether animal, vegetable, or fossil, wherein all the qualities or virtues of the ingredients of the mixed are comprehended in a small compass.

Ens martis. An oxide of iron.

Ens primum solare. Antimony.

Ens veneris. The muriate of copper.

ENSATÆ. (From *ensis*, a sword.) The name of a natural order of plants, consisting of such as have sword-shaped leaves.

E'NSIFORM. (*Ensiformis; from ensis* a sword, and *forma*, resemblance.) Sword-like.

1. A term applied to some parts from their resemblance; as the ensiform cartilage.

2. In botany, a leaf is called *folium ensiforme*, which has two edges, and tapers to a point, like a sword. See *Leaf.*

Ensta'ctum. (From εν, and ϛαζω, to instil.) A liquid medicine, which is applied *instillatim*, or drop by drop.

ENTASIA. (From εντασις, *intentio vehementia.*) A name of a genus of diseases in Good's Nosology. Class, *Neurotica; Order, Cinetica.* Constrictive spasm. It has eight species, viz. *Entasia priapismus; loxia; articularis; systremma; trismus; tetanus; lyssa; acrotismus.*

Enta'tica. (From εντεινω, to strain.) Provocatives, or whatever excites venereal inclination.

E'NTERA. (From εντος, within.)

1. The bowels.

2. Hippocrates calls by this name the bags in which medicines for fomentations were formerly enclosed.

ENTERADE'NES. (From εντερον, an intestine, and αδην a gland.) The intestinal glands.

Entere'nchyta. (From εντερα, the bowels, and εγχυω, to infuse into.) An instrument for administering clysters. A clyster-pipe.

ENTERICA. (From εντερον, *intestinum alvus.*) The name of the first order, class *Cœliaca*, of Good's Nosology. Diseases affecting the alimentary canal. Its genera are, *Odontia; Ptyalismus; Dysphagia; Dipsosis; Limosis; Colica; Coprostasis; Diarrhœa; Cholera; Enterolithus; Helminthia; Proctica.*

ENTERI'TIS. (From εντερον, an intestine.) Inflammation of the intestines. It is a genus of disease in the class *Pyrexiæ*, and order *Phlegmasiæ* of Cullen, and is known by the presence of pyrexia, fixed pain in the abdomen, costiveness, and vomiting. The causes of enteritis are much the same as those of gastritis, being occasioned by acrid substances, indurated fæces, long-continued and obstinate costiveness, spasmodic colic, and a strangulation of any part of the intestinal canal; but another very general cause is the application of cold to the lower extremities, or to the belly itself. It is a disease which is most apt to occur at an advanced period of life, and is very liable to a relapse.

It comes on with an acute pain, extending in general over the whole of the abdomen; but more especially round the navel, accompanied with eructations, sickness at the stomach, a vomiting of bilious matter, obstinate costiveness, thirst, heat, great anxiety, and a quick and hard small pulse. After a short time, the pain becomes more severe, the bowels seem drawn together by a kind of spasm, the whole region of the abdomen is highly painful to the touch, and seems drawn together in lumpy contractions; invincible costiveness prevails, and the urine is voided with great difficulty and pain.

The inflammation continuing to proceed with violence, terminates at last in gangrene; or abating gradually, it goes off by resolution.

Enteritis is always attended with considerable danger, as it often terminates in gangrene in the space of a few hours from its commencement; which event is marked by the sudden remission of pain, sinking of the pulse, shrinking of the features, and distention of the belly; and it frequently proves fatal likewise, during the inflammatory stage. If the pains abate gradually, if natural stools be passed, if an universal sweat, attended with a firm equal pulse, comes on, or if a copious discharge of loaded urine, with the same kind of pulse, takes place, a resolution and favourable termination may be expected.

Dissections of this disease show that the inflammation pervades the intestinal tube to a very considerable extent; that adhesions of the diseased portion to contiguous parts are formed; and that, in some cases, the intestines are in a gangrenous state, or that ulcerations have formed. They likewise show, that, besides obstinate obstructions, introsusception, constrictions, and twistings, are often to be met with; and that, in most cases, the peritonæum is more or less affected, and is perceived, at times, to be covered with a layer of coagulable lymph. The treatment must be begun by taking blood freely from the arm, as far as the strength of the patient will allow: but the disease occurring more frequently in persons rather advanced in years, and of a constitution somewhat impaired, it becomes more important to limit this evacuation and rely in a great measure on the effects of a number of leeches, applied to the abdomen. Another very useful step is to put the patient into a hot bath, which may presently induce faintness; or where this cannot be procured, fomenting the abdomen assiduously. When the symptoms are thus materially relieved, an ample blister should be applied. It becomes also of the first importance to clear out the bowels: a copious laxative clyster will evacuate the inferior part of the canal, and solicit the peristaltic motion downwards; and the milder cathartics, as castor oil, neutral salts, &c. in divided doses, may gradually procure a passage. But where the disease has been preceded by costiveness, more active articles will probably be necessary, as calomel, compound extract of colocynth, infusion of senna, with salts, &c. If the stomach be irritable, the effervescing saline draught may enable it to retain the requisite cathartics. Another plan, often very successful, is giving opium in a full dose, particularly in conjunction with calomel, taking care to follow it up by some of the remedies above mentioned, till the bowels are relieved; which effect it appears to promote by its soothing antispasmodic power. Afterwards we may endeavour to keep up diaphoresis, and recruit the strength of the patient by a mild nourishing diet; taking care to guard against accumulation of fæces, exposure to cold, or any thing else likely to occasion a relapse.

ENTERO′. (From εντερον, an intestine.) Names compounded of this word belong to things which resemble an intestine; or to parts connected with, or diseases of some part of, the intestine.

ENTEROCE′LE. (From εντερον, an intestine, and κηλη, a tumour.) An intestinal rupture or hernia. Every hernia may be so called that is produced by the protrusion of a portion of intestine, whether it is in the groin, navel, or elsewhere.

ENTERO-EPIPLOCELE. (From εντερον, an intestine, επιπλοον, the epiploon, and κηλη, a tumour.) A rupture formed by the protrusion of part of an intestine, with a portion of the epiploon.

ENTERO-HYDROCELE. (From εντερον, an intestine, υδωρ, water, and κηλη, a tumour.) This must mean a common scrotal hernia, with a good deal of water in the hernial sac; or else a hernia congenita, (in which the bowels descend into the tunica vaginalis testis,) attended with a collection of fluid in the cavity of this membrane.

ENTEROLITHUS. (From εντερον, an intestine, and λιθος, a stone.) The name of a genus of disease, Class, *Cæliaca*; Order, *Enterica*, in Good's Nosology. Intestinal concretion. It embraces three species, viz. *Enterolithus bezoar*; *calculus*; *scybalum*.

ENTERO′MPHALUS. (From εντερον, an intestine, and ομφαλος, the navel.) An umbilical hernia, produced by the protrusion of a portion of intestine.

ENTERO′PHYTUM. (From εντερον, an intestine, and φυτον, a plant.) A plant which grows in the form of a gut, the sea-chitterling.

ENTERORA′PHIA. (From εντερον, an intestine, and ραφη, a suture.) A suture of the intestines, or the sewing together the divided edges of an intestine.

ENTEROSCHEOCE′LE. (From εντερον, an intestine, οσχεον, the scrotum, and κηλη, a rupture.) A scrotal hernia, or rupture of the intestines into the scrotum.

ENTHE′MATA. (From εντιθημι, to put in.) Anti-inflammatory styptics.

E′NTHLASIS. A contusion with the impression of the instrument by which it happened.

Entire leaf. See *Integerrimus.*

ENTROCHI. A genus of extraneous fossils, made up of round joints, which, when separate and loose, are called *trochitæ*.

ENTRO′PIUM. (*Entropium*, *i*. n.; from εν, and τρεπω, to turn.) A disease of the eyelids, occasioned by the eyelashes and eyelid being inverted towards the bulb of the eye.

ENTYPO′SIS. (From εντυποω, to make an impression.) 1. The acetabulum.

2. The scapula, or concave bone of the shoulder.

E′NULA. (A corruption of *henula*, or *Helenium*, from *Helene*, the island where it grew.) See *Inula helenium.*

ENULA CAMPANA. See *Inula helenium.*

ENU′LON. (From εν, and ουλὸν, the gums.) The internal flesh of the gums, or that part of them which is within the mouth.

ENURE′SIS. (*Eneuresis*, *is*. f.; from ενουρεω, to make water. An incontinency or involuntary flow of urine. This disease usually proceeds either from relaxation or a paralytic affection of the sphincter of the bladder, induced by various debilitating causes, as too free a use of spirituous liquors, manustupration, and excess in venery; or it arises from compression on the bladder, from a diseased state of the organ, or from some irritating substance contained in its cavity. It is arranged in the class *Locales*, and order *Apocenoses* of Cullen, and contains two species: 1. *Enuresis atonica*, the sphincter of the bladder having lost its tone from some previous disease. 2. *Enuresis ab irritatione, vel compressione vesicæ*, from an irritation or compression of the bladder.

EPACMA′STICUS. (From επι, and ακμαζω, to increase.) A fever which is increasing in malignity.

EPA′CME. (From επακμαζω, to increase.) The increase, or exacerbation of a disease.

EPAGO′GIUM. (From επαγω, to draw over.) The præpuce, or that part of the penis which is drawn over the glans, according to Dioscorides.

EPANADIDO′NTES. (From επαναδιδωμι, to increase.) A term applied to fevers which continue to increase in their degree of heat.

EPANADIPLO′SIS. (From επαναδιπλοω, to reduplicate.) The reduplication of a fit of a semitertian fever; that is, the return of the cold fit before the hot fit is ended.

EPANA′STASIS. (From επι, and ανιςημι, to excite.) A tubercle, or small pustule upon the skin.

EPANCYLO′TUS. (From επι, and αγκυλος, crooked.) A sort of crooked bandage in Oribasius.

EPANETUS. (From Ἐπανειμι, to return.) The name of a genus, Class, *Hæmatica*; Order, *Pyretica*, in Good's Nosology. Remittent fever. It has three species, viz. *Epanetus nutis*; *malignus*; *hectica*.

EPA′RMA. (From επαιρω, to elevate.) *Eparsis.* Any kind of tumour, but frequently applied to one of the parotid gland.

EPA′RSIS. See *Eparma.*

EPASMA′STIGA FEBRIS. A fever is so called by Bellini, and others, while it is in its increase. See *Epacmasticus.*

EPE′NCRANIS. (From επι, εν, in, and κρανιον, the skull.) The name of the cerebellum.

EPHEBÆ′UM. (From επι, and ηβη, the groin.) The hair upon the pubes.

E′PHEDRA. (From εφεζομαι, to sit upon.) *Ephedrana.* 1. The buttocks.

2. A species of horse-tail.

EPHE′DRANA. See *Ephedra.*

EPHE′LCIS. (From επι, upon, and ελκος, an ulcer.) 1. The crust of an ulcer.

2. Hardened purulent expectoration.

EPHE′LIS. (*Ephelis*; from επι, and ηλιος, the sun.) A sun spot. A solitary, or aggregated spot, attacking most commonly the face, back of the hand, and breast, from exposure to the sun.

EPHE′MERA. (From επι, upon, and ημερα, a day.) 1. A disease of a day's duration.

2. A fever which begins, is perfectly formed, and runs through its course in the space of twelve hours.

EPHEME'RIDES. (*Ephemeris, idis.* f.; from εφημερις, an almanack: so called because, like the moon's age, they may be foretold by the almanack.) Diseases which return at particular times of the moon.

EPHIA'LTES. (From εφαλλομαι, to leap upon: so called because it was thought a dæmon leaped upon the breast.) Incubus, or night-mare. See *Oneirodynia.*

Ephia'ltia. (From *ephialtes*, the night-mare: so called because it was said to cure the night-mare.) The herb peony.

EPHIDRO'SIS. (From εφιδροω, to perspire.) *Sudatio. Mador.* A violent and morbid perspiration. A genus of disease in the class *Locales*, and order *Apocenoses* of Cullen.

EPHI'PPIUM. A saddle, which it is thought to resemble. See *Sella turcica.*

E'phodos. (From επι, and οδος, a way.) In Hippocrates it hath three significations:

1. The ducts or passages, by which the excrements of the body are evacuated.

2. The periodical attack of a fever, from the common use of it to express the attack of thieves.

3. The access of similar or dissimilar things, which may be useful or hurtful to the body.

Epia'ltes. See *Ephialtes.*

Epi'alus. (From ηπιον, gently, and αλεαζω, to heat.) *Epialos.* An ardent fever, in which both heat and cold are felt in the same part at the same time. Galen defines it to be a fever in which the patient labours under a preternatural heat and a coldness at the same time. The ancient Latins call it *Quercera.*

Epi'bole. (From επιβαλλω, to press upon.) The night-mare, or ephialtes.

Epica'nthis. (From επι, and κανθος, the angle of the eye.) The angle of the eye.

Epica'rpium. (From επι, upon, and καρπος, the wrist.) A medicine applied to the wrist.

Epica'uma. (From επι, and καιω, to burn.) A burn.

Epicau'sis. A burn.

Epi'ceras. (From επι, and κερας, a horn: so called because its pods are shaped like a horn.) See *Trigonella fœnum græcum.*

Epicera'stica. (From επι, and κεραννυμι, to mix.) Medicines which, by mixing with acrimonious juices, temper them and render them less troublesome; as emollients.

Epicheire'sis. (From επι, and χειρ, the hand.) A manual operation.

Epi'cholus. (From επι, and χολη, the bile.) Bilious.

Epicho'rdis. (From επι, upon, and χορδη, a gut.) The mesentery.

Epicho'rios. (From επι, upon, and χορα, a region.) The same as epidermis.

EPICHROSIS. (From επιχρωσις, a coloured or spotted surface.) The name of a genus of disease. Class, *Eccritica;* Order, *Acrotica*, in Good's Nosology. Macular skin, or simple discoloration of the surface. It embraces seven species, viz. *Epichrosis leucasmus; spilus; lenticula; ephelis; aurigo; pœcilia; alphosis.*

Epicœlis. (From επι, upon, and κοιλις, the eyelid.) The upper eyelid.

EPICO'LIC. (*Epicolicus;* from επι, upon, and κωλον, the colon.) That part of the abdomen which lies over the head of the cœcum and the sigmoid flexure of the colon, is called the epicolic region.

Epicopho'sis. (From επι, and κωφος, deaf.) A total deafness.

EPICRA'NIUM. (From επι, and κρανιον, the cranium.) The common integuments, aponeurosis, and muscular expansion which lie upon the cranium.

Epicra'nius. See *Occipito frontalis.*

EPI'CRASIS. (From επι, and κεραννυμι, to temper.) A critical evacuation of bad humours, an attemperation of bad ones. When a cure is performed in the alterative way, it is called *per Epicrasin.*

EPICRISIS. (From επι, and κρινω, to judge from.) A judgment of the termination of a disease from present symptoms.

Epicte'nium. (From επι, about, and κτεις, the pubes.) The parts above and about the pubes.

Epicye'ma. (From επι, upon, and κυω, to conceive.) *Epicyesis.* Superfœtation.

Epicye'sis. See *Epicyema.*

EPIDE'MIC. (*Epidemicus;* from επι, upon, and δημος, the people.) A contagious disease is so termed, that attacks many people at the same season, and in the same place; thus putrid fever, plague, dysentery, &c. are often epidemic.

EPIDE'NDRUM. (From επι, upon, and δενδρον, a tree; because all this genus of plants grow parasitically on the trunk or branches of trees.) The name of a genus of plants in the Linnæan system. Class, *Gynandria;* Order, *Monandria.*

Epidendrum vanilla. The systematic name of the vanelloe plant. *Vanilla; Banlia; Banilas; Aracus aromaticus; Epidendrum—scandens, foliis ovato oblongis nervosis sessilibus caulinis, cirrhis spiralibus* of Linnæus. The vanelloe is a long, flattish pod, containing, under a wrinkled brittle shell, a reddish brown pulp, with small shining black seeds, which have an unctuous aromatic taste, and a fragrant smell like that of some of the finer balsams heightened with musk. Although chiefly used as perfumes, they are said to possess aphrodisiac virtues.

Epi'deris. (From επι, and δερας, the skin.) The clitoris.

EPIDE'RMIS. (From επι, upon, and δερμα, the true skin.) The scarf-skin. See *Cuticle.*

Epi'desis. (From επι, upon, and δεω, to bind.) A bandage to stop a discharge of blood.

Epide'smus. (From επι, upon, and δεὼ, to bind.) A bandage by which splints, bolsters, &c. are secured.

EPIDI'DYMIS. (From επι, upon, and διδυμος, a testicle.) A hard, vascular, oblong substance, that lies upon the testicle, formed of a convolution of the *vas deferens.* It has a thick end, which is convex, and situated posteriorly; and a thin end, which is rather flat, and situated inferiorly. The epididymis adheres to the testicle by its two extremities only, for its middle part is free, forming a bag, to which the tunica vaginalis of the testicle is attached.

Epi'dosis. (From επιδιδωμι, to grow upon.) A preternatural enlargement of any part.

EPIDOTE. Pistacite of Werner. Acaulicone from Norway. A sub-species of prismatoidal augite. A compounded ore, containing silica, alumina, lime, oxide of iron, oxide of manganese found in primitive beds and veins, along with augite, hornblende, calcareous spar, &c.

Epi'drome. (From επιδρεμω, to run upon.) An afflux of humours.

EPIGA'STRIC. (*Epigastricus;* from επι, upon, or above, and γαϛηρ, the stomach.) That part of the abdomen that lies over the stomach, is called the epigastric region; it reaches from the pit of the stomach to an imaginary line above the navel, supposed to be drawn from one extremity of the last of the false ribs to the other. Its sides are called hypochondria, and are covered by the false ribs, between which lies the epigastrium.

EPIGA'STRIUM. (From επι, upon, or above, and γαςηρ, the belly.) The part immediately over the stomach.

EPIGENESIS. A name given by the ancients, to that theory of generation which consists in regarding the fœtus as the joint production of matter afforded by both sexes.

EPIGENNE'MA. (From επιγινομαι, to generate upon.) 1. The fur on the tongue.

2. An accessory symptom.

EPIGENNE'SIS. See *Epigennema.*

EPIGINO'MENA. (From επιγινομαι, to succeed or supervene.) Galen says, they are those symptoms which naturally succeed, or may be expected in the progress of a disease; but Fœsius says, they are accessions of some other affection to diseases, which never happen but in stubborn and malignant diseases.

EPIGLO'SSUM. (From επι, upon, and γλωσσα, the tongue: so called because a lesser leaf grows above the larger in the shape of a tongue.) The Alexandrian laurel, a species of *Ruscus.*

EPIGLO'TTIS. (From επι, upon, and γλωττις, the tongue.) The cartilage at the root of the tongue that falls upon the glottis or superior opening of the larynx. Its figure is nearly oval; it is concave posteriorly, and convex anteriorly. Its apex or superior extremity is loose, and is always elevated upwards by its own elasticity. While the back of the tongue is drawn backwards in swallowing, the epiglottis is put over the aperture of the larynx, hence it shuts up the passage from the mouth into the larynx. The base of the epiglottis is fixed to the thyroid cartilage, the os hyoides, and the base of the tongue, by a strong ligament.

EPIGLO'TTUM. (From επιγλωττις, the epiglottis, which it resembles in shape.) An instrument mentioned by Paracelsus for elevating the eyelids.

EPIGLOU'TIS. (From επι, upon, and γλουτος, the buttocks.) The superior parts of the buttocks.

EPIGO'NATIS. (From επι, upon, and γονυ, the knee.) The patella or knee-pan.

EPIGO'NIDES. (From επι, and γονυ, the knee.) The muscles inserted into the knees.

EPI'GONUM. (From επιγινομαι, to proceed upon.) A superfœtation.

EPILE'MPSIS. See *Epilepsy.*

EPILE'NTIA. Corrupted from epilepsia.

EPILEPSY. (*Epilepsia, æ.* f.; from επιλαμβανω, to seize upon: so called, from the suddenness of its attack.) It is also called falling-sickness, from the patient suddenly falling to the ground on an attack of this disease. By the ancients it was termed, from its affecting the mind, the most noble part of the rational creature, the sacred disease. It consists of convulsions with sleep, and usually froth issuing from the mouth. It is a genus of disease in the class *Neuroses,* and order *Spasmi* of Cullen, and contains three species:

1. *Epilepsia cerebralis;* attacking suddenly without manifest cause, and not preceded by any unpleasant sensation, unless perhaps some giddiness or dimness of sight.

2. *Epilepsia sympathica;* without manifest cause, but preceded by a sensation of an aura ascending from some part of the body to the head.

3. *Epilepsia occasionalis;* arising from manifest irritation, and ceasing on the removal of this. It comprehends several varieties:—a. *Epilepsia traumatica,* arising from an injury of the head: b. *Epilepsia à dolore,* from pain: c. *Epilepsia verminosa,* from the irritation of worms: d. *Epilepsia à veneno,* from poisons: e. *Epilepsia exanthematica,* from the repulsion of cutaneous eruptions: f. *Epilepsia à cruditate ventriculi,* from crudities of the stomach: g. *Epilepsia ab inanitione,* from debility: h. *Epilepsia uterina,* from hysterical affections: i. *Epilepsia ex onanismo,* from onanism, &c.

Epilepsy attacks by fits, and after a certain duration goes off, leaving the person most commonly in his usual state; but sometimes a considerable degree of stupor and weakness remain behind, particularly where the disease has frequent recurrences. It is oftener met with among children than grown persons, and boys seem more subject to its attacks than girls. Its returns are periodical, and its paroxysms commenced more frequently in the night than in the day, being somewhat connected with sleep. It is sometimes counterfeited, in order to extort charity or excite compassion.

Epilepsy is properly distinguished into sympathic, and idiopathic, being considered as sympathic, when produced by an affection in some other part of the body, such as acidities in the stomach, worms, teething, &c. as idiopathic when it is a primary disease, neither dependent on nor proceeding from any other.

The causes which give rise to epilepsy are blows, wounds, fractures, and other injuries, done to the head by external violence, together with lodgments of water in the brain, tumours, concretions and polypi. Violent affections of the nervous system, sudden frights, fits of passion, great emotions of the mind, acute pains in any part, worms in the stomach or intestines, teething, the suppression of long-accustomed evacuations, too great emptiness or repletion, and poisons received into the body, are causes which likewise produce epilepsy. Sometimes it is hereditary, and at others it depends on a predisposition arising from mobility of the sensorium, which is occasioned either by plethora, or a state of debility.

An attack of epilepsy is now and then preceded by a heavy pain in the head, dimness of sight, noise in the ears, palpitations, flatulency in the stomach and intestines, weariness, and a small degree of stupor, and in some cases, there prevails a sense of something like a cold vapour or aura arising up to the head; but it more generally happens that the patient falls down suddenly without much previous notice; his eyes are distorted, or turned so that only the whites of them can be seen; his fingers are closely clinched, and the trunk of his body, particularly on one side, is much agitated; he foams at the mouth, and thrusts out his tongue, which often suffers great injury from the muscles of the lower jaw being affected; he loses all sense of feeling, and not unfrequently voids both urine and fæces involuntarily.

The spasms abating, he recovers gradually; but on coming to himself feels languid and exhausted, and retains not the smallest recollection of what has passed during the fit.

When the disease arises from an hereditary disposition, or comes on after the age of puberty, or where the fits recur frequently, and are of long duration, it will be very difficult to effect a cure: but when its attacks are at an early age, and occasioned by worms, or any accidental cause, it may in general be removed with ease. In some cases, it has been entirely carried off by the occurrence of a fever, or by the appearance of a cutaneous eruption. It has been known to terminate in apoplexy, and in some instances to produce a loss of the powers of the mind, and to bring on idiotism.

The appearances usually to be observed on dissection, are serous and sanguineous effusion, a turgid tense state of the vessels of the brain without any effusion, a dilatation of some particular part of the brain, excrescences, polypi, and hydatids adhering to it, and obstructing its functions, and likewise ulcerations.

During the epileptic paroxysm in general, little or nothing is to be done, except using precautions, that the patient may not injure himself; and it will be prudent to remove any thing which may compress the veins of the neck, to obviate congestion in the head. Should there be a considerable determination of blood to this part, or the patient very plethoric, it may be proper, if you can keep him steady, to open a vein, or the temporal artery; and in weakly constitutions the most powerful antispasmodics might be tried in the form of clyster, as they could hardly be swallowed: but there is very seldom time for such measures. In the intervals the treatment consists: 1. In obviating the several exciting causes. 2. In correcting any observable predisposition. 3. In the use of those means, which are most likely to break through the habit of recurrence.

I. The manner of fulfilling the first indication requires little explanation; after an injury to the head, or where there is disease of the bone, an operation may be necessary, to remove irritation from the brain; in children teething, the gums ought to be lanced: where the bowels are foul or worms suspected, active purgatives should be exhibited, &c. In those instances, in which the aura epileptica is perceived, it has been recommended to destroy the part, where it originates, or divide the nerve going to it, or correct the morbid action by a blister, &c.; such means would certainly be proper when there is any disease discoverable in it. Making a tight ligature on the limb above has sometimes prevented a fit; but, perhaps, only through the medium of the imagination.

II. Where a plethoric state appears to lay the foundation of the disease, which is often the case, the patient must be restricted to a low diet, frequent purges exhibited, and the other excretions kept up, and he should take regular moderate exercise, avoiding whatever may determine the blood to the head; and to counteract such a tendency, occasional cupping, blisters, issues, &c. may be useful, as well as the shower-bath; but in urgent circumstances, the lancet ought to be freely used. If, on the contrary, there are marks of inanition and debility, a generous diet, with tonic medicines, and other means of strengthening the system, will be proper. The vegetable tonics have not been so successful in this disease as the metallic preparations, particularly the sulphate of zinc, the nitrate of silver, and the ammoniated copper, but this cannot perhaps be so safely persevered in: where the patient is remarkably exsanguious, chalybeates may answer better; and, in obstinate cases, the arsenical solution might have a cautious trial. In irritable constitutions, sedatives are indicated, as digitalis, opium, &c.: but the free use of opium is restricted by a tendency to congestion in the head. Where syphilis appears to be concerned, a course of mercury is proper; in scrophulous habits, bark, or steel, with iodine, soda, and sea-bathing; and so on.

III. The third division of remedies comes especially in use, where the fits are frequent, or where their recurrence can be anticipated: emetics will often prevent them, or a full dose of opium; also other powerful antispasmodics, as æther, musk, valerian, &c.: or strong odours, and in short any thing producing a considerable impression on the system. Bark taken largely might perhaps be more successful on this principle. The disease has sometimes been cured, especially when originating from sympathy, by inspiring fear or horror; and many frivolous charms may, no doubt, have taken effect through the medium of the imagination. Also long voyages have removed it, which might especially be hoped for at the age of puberty, particularly if a considerable change in the mode of life were made in other respects; those who had lived indolently being obliged to exert themselves. the diet properly adapted to the state of the system, &c.

EPILO'BIUM. (From επι λοβου ιον, a violet or beautiful flower, growing on a pod.) The name of a genus of plants in the Linnæan system. Class, *Octandria;* Order, *Monogynia.*

EPILOBIUM ANGUSTIFOLIUM. Rose-bay-willow herb. The young tender shoots cut in the spring, and dressed as asparagus, are little inferior to it.

EPIME'DIUM. The plant barren-wort.

EPIMO'RIUS. (From επι, and μειρω, to divide.) An obsolete term, formerly applied to an unequal pulse.

EPIMY'LIS. (From επι, and μυλη, the knee.) The patella or knee-bone.

EPINENEU'CUS. (From επινευω, to nod or incline.) An unequal pulse.

EPINO'TIUM. (From επι, upon, and νωτος, the back.) The shoulder-blade.

EPINY'CTIS. (From επι, and νυξ, night.) A pustule, which rises in the night, forming an angry tumour on the skin of the arms, hands, and thighs, of the size of a lupine, of a dusky red, and sometimes of a livid and pale colour, with great inflammation and pain. In a few days it breaks, and sloughs away.

EPIPA'CTIS. (From επιπακτοω, to coagulate.) A plant mentioned by Dioscorides; and so named because its juice was said to coagulate milk.

EPIPAROXY'SMUS. (From επι, upon, and παροξυσμος, a paroxysm.) An unusual frequency of febrile exacerbation.

EPIPA'STUM. (From επι, upon, and πασσω, to sprinkle.) Any powdered drug sprinkled on the body.

EPIPE'CHYS. (From επι, above, and πηχυς, the cubit.) That part of the arm above the cubit.

EPIPHLOGI'SMA. (From επι, upon, and φλογιζω, to inflame.) 1. Violent inflammation, or burning heat in any part, attended with pain, tumour, and redness.

2. A name given by Hippocrates to the shingles.

EPI'PHORA. (From επιφερω, to carry forcibly.) The watery eye. An involuntary flow of tears. A superabundant flowing of a serous or aqueous humour from the eyes. A genus of disease in the class *Locales*, and order *Apocenoses*, of Cullen. The humour which flows very copiously from the eye in epiphora, appears to be furnished, not only by the lachrymal gland, but from the whole surface of the conjunctive membrane, Meibomius's glands, and the caruncula lachrymalis; which increased and morbid secretion may be induced from any stimulus seated between the globe of the eye and lids, as sand, acrid fumes, and the like; or it may arise from the stimulus of active inflammation; or from the acrimony of scrophula, measles, small-pox, &c. or from general relaxation. The disease may also arise from a more copious secretion of tears, than the puncta lachrymalia can absorb, or, as is most common, from an obstruction in the lachrymal canal, in consequence of which the tears are prevented from passing freely from the eye into the nose.

EPIPHRAGMA. The slender membrane which sometimes shuts the peristoma of mosses, as is seen in *Polytricum.*

EPI′PHYSIS. (From επι, upon, and φυω, to grow.) Any portion of bone growing upon another, but separated from it by a cartilage.

EPIPLA′SMA. (From επι, upon, and πλασσω, to spread.) 1. A poultice.

2. A name for an application of wheat meal, boiled in hydrelæum, to wounds.

EPIPLO. (From επιπλοον, the omentum.) Names compounded of this word belong to parts connected with, or diseases of, the epiploon.

EPIPLOCE′LE. (From επιπλοον, the omentum, and κηλη, a tumour.) An omental hernia. A rupture produced by the protrusion of a portion of the omentum. See *Hernia omentalis.*

EPIPLOCOMI′STIS. (From επιπλοον, the omentum, and κομιζω, to carry.) One who has the omentum morbidly large.

Epiploic appendages. See *Appendiculæ epiploicæ.*

EPIPLOI′TIS. (From επιπλοον, the omentum.) An inflammation of the process of the peritonæum, that forms the epiploon or omentum. See *Peritonitis.*

EPIPLOO′MPHALON. (From επιπλοον, the omentum, and ομφαλος, the navel.) An omental hernia protruding at the navel.

EPI′PLOON. (From επιπλοω, to sail over, because it is mostly found floating, as it were, upon the intestines.) See *Omentum.*

EPIPLOSCHEOCE′LE. (From επιπλοον, the omentum, οσχεον, the scrotum, and κηλη, a tumour or hernia.) A rupture of the omentum into the scrotum, or a scrotal hernia containing omentum.

EPIPO′LASIS. (From επιπολαζω, to swim on the top.) 1. A fluctuation of humours.

2. A species of chemical sublimation.

EPIPO′MA. (From επι, upon, and πωμα, a lid.) An instrument to cover the shoulder in a luxation.

EPIPORO′MA. (From επιπωρεω, to harden.) A hard tumour about the joints.

EPIPTY′XIS. (From επιπτυσσω, to close up.) A spasmodic closing of the lips.

EPIPYRE′XIS. (From επι, and πυρεττω, to be feverish.) A rapid exacerbation in a fever.

EPIRIGE′SIS. (From επι, and ριγεω, to become cold.) An unusual degree of cold, or repetition of rigors.

EPI′RRHOE. (From επι, upon, and ρεω, to flow.) An influx or afflux of humours to any part.

EPISARCI′DIUM. (From επι, upon, and σαρξ, the flesh.) An anasarca, or dropsy, spread between the skin and flesh.

EPISCHE′SES. (From επισχεω, to restrain.) A suppression of excretions. It is an order in the class *Locales* of Cullen's Nosology.

EPI′SCHIUM. (From επι, upon, and ισχιον, the hip-bone.) The os pubis.

EPISCOPA′L. (From *episcopus*, a bishop, or mitred dignitary.) Of, or belonging to a bishop: applied to a valve at the orifice between the left auricle and ventricle of the heart. See *Mitral valve.*

EPISPA′SMUS. (From επισπαω, to draw together.) A quick inspiration.

EPISPA′STIC. (*Epispasticus*; from επισπαω, to draw together.) Those substances which are capable, when applied to the surface of the body, of producing a serous or puriform discharge, by exciting a previous state of inflammation. The term, though comprehending likewise issues and setons, is more commonly restricted to blisters—those applications which, exciting inflammation on the skin, occasion a thin serous fluid to be poured from the exhalants, raise the cuticle, and form the appearance of a vesicle. This effect arises from their strong stimulating power, and to this stimulant operation and the pain they excite, are to be ascribed the advantages derived from them in the treatment of disease. The evacuation they occasion is too inconsiderable to have any material effect. See *Blister.*

EPISPHÆ′RIA. (From επι, and σφαιρα, a sphere: so called from the spherical shape of the brain.) The windings of the exterior surface of the brain; or the winding vessels upon it.

EPISTA′GMUS. (From επι, and σταζω, to trickle down.) A catarrh.

EPISTAPHYLI′NUS. (From επι, and σταφυλη, the uvula.) See *Uvula.*

EPISTA′XIS. (From επισταζω, to distil from.) Bleeding at the nose, with pain, or fulness of the head. A genus of disease arranged by Cullen in the class *Pyrexiæ*, and order *Hæmorrhagiæ.*

Persons of a sanguine and plethoric habit, and not yet advanced to manhood, are very liable to be attacked with this complaint; females being much less subject to it than males, particularly after menstruation.

Epistaxis comes on at times without any previous warning; but at others, it is preceded by a pain and heaviness in the head, flushing in the face, heat and itching in the nostrils, a throbbing of the temporal arteries, and a quickness of the pulse. In some instances a coldness of the feet, and shivering over the whole body, together with a costive belly, are observed to precede an attack of this hæmorrhage.

This complaint is to be considered as of little consequence, when occurring in young persons being never attended with any danger; but when it arises in those who are advanced in life, flows profusely, and returns frequently, it indicates too great fulness of the vessels of the head, and not unfrequently precedes apoplexy, palsy, &c. and, therefore, in such cases, is to be regarded as a dangerous disease. When this hæmorrhage arises in any putrid disorder, it is to be considered as a fatal symptom.

In general, we need not be very anxious to stop a discharge of blood from the nose, particularly where there are marks of fulness of the vessels of the head: but if it occurs under a debilitated state of the system, or becomes very profuse, means must be employed to suppress it. These are chiefly of a local nature; applying pressure to the bleeding vessels, introducing astringents into the nostrils, as solutions of alum, sulphate of zinc, sulphate of copper, &c. applying cold to the head or to some very sensible part of the skin, as in the course of the spine, &c. At the same time the patient should be kept in the erect position. If the hæmorrhage be of an active character, the antiphlogistic regimen should be carefully observed: the patient kept cool and quiet; the saline cathartics, refrigerants, as nitrate of potassa and the acids, digitalis, diaphoretics, &c. administered internally; and blood may be taken from the temples by leeches, or even from the arm, if the patient be very plethoric. Sometimes, after the failure of other means, closing the posterior as well as anterior outlets from the nose, and preventing the escape of the blood for some time mechanically, has been successful; and this might be particularly proper, where it was discharged copiously into the fauces, so as to endanger suffocation, on the patient falling asleep.

EPISTHO′TONOS. (From επισθεν, forwards, and τεινω, to extend.) A spasmodic affection of muscles drawing the body forwards. See *Tetanus*.

Episto′mion. (From επι, upon, and ϛομα, a mouth.) 1. A stopper for a bottle.

2. A vent-hole of a furnace, called the register.

Epistro′phalus. (From επι, upon, and ϛρεφω, to turn about.) *Epistrophia*, and *Epistrophis*. Applied to the first vertebra of the neck, because it turns about upon the second as upon an axis.

Epi′strophe. (From επιϛρεφω, to invert.) 1. An inversion of any part, as when the neck is turned round.

2. A return of a disorder which has ceased.

EPI′STROPHEUS. (From επιϛροφαω, to turn round, because the head is turned upon it.) The second cervical vertebra. See *Dentatus*.

Epi′strophis. See *Epistrophalus*.

Epi′tasis. (From επι, and τεινω, to extend.) The beginning and increase of a paroxysm or disease.

EPITHE′LIUM. The cuticle on the red part of the lips.

Epithe′ma. (From επι, upon, and τιθημι, to apply.) A term formerly applied to a lotion, fomentation, or any external application.

Epithema′tium. The same.

Epi′thesis. (From επι, and τιθημι, to cover, or lay upon.) The rectification of crooked limbs by means of instruments.

EPITHY′MUM. (From επι, upon, and θυμος, the herb thyme.) See *Cuscuta epithymum*.

Epo′de. (From επι, over, and ωδη, a song.) *Epodos*. The method of curing distempers by incantation.

Epom′is. (From επι, upon, and ωμος, the shoulder.) The acromion, or upper part of the shoulder.

Epompha′lium. (From επι, upon, and ομφαλος, the navel.) An application to the navel.

EPSOM. The name of a village in Surrey, about eighteen miles from London, in the neighbourhood of which is a considerable mineral spring, called Epsom water. *Aqua Epsomensis*. This water evaporated to dryness leaves a residuum, the quantity of which has been estimated from an ounce and a half in the gallon, to five drachms and one scruple. Of the total residuum, by far the greater part, about four or five-sixths, is sulphate of magnesia mixed with a very few muriates, such as that of lime, and probably magnesia, which render it very deliquescent, and increase the bitterness of taste, till purified by repeated crystallisations. There is nothing sulphurous or metallic ever found in this spring. The diseases in which it is employed are similar to those in which we use Seidlitz water. There are many other of the simple saline springs that might be enumerated, all of which agree with that of Epsom, in containing a notable proportion of some purging salt, which, for the most part, is either sulphate of magnesia, or sulphate of soda, or often a mixture of both, such as Acton, Kilburne, Bagnigge Wells, Dog and Duck, St. George's Fields, &c.

Epsom salt. A purging salt formerly obtained by boiling down the mineral water found in the vicinity of Epsom in Surrey. It is at present prepared from sea water, which, after being boiled down, and the muriate of soda separated, deposits numerous crystals, that consist chiefly of sulphate of magnesia, and sold in the shops under the name of sal catharticus amarus, or bitter purging salt. See *Magnesiæ sulphas*.

EPU′LIS. (From επι, and ουλα, the gums.) A small tubercle on the gums. It is said sometimes to become cancerous.

EPULO′TIC. (*Epuloticus*; from επουλοω, to cicatrize.) A term given by surgeons to those applications which promote the formation of skin.

EQUISE′TUM. (From *equus*, a horse, and *seta*, a bristle: so named from its resemblance to a horse's tail.) 1. the name of a genus of plants in the Linnæan system. Class, *Cryptogamia*; Order, *Filices*.

2. The pharmacopœial name of the *Cauda equina*. See *Hippuris vulgaris*.

Equisetum arvense. See *Hippuris vulgaris*.

EQUITANS. Equitant. This term is applied to leaves, which are disposed in two opposite rows, and clasp each other by their compressed base; as in *Narthecium ossifragum*.

EQUIVALENTS. A term introduced into chemistry by Dr. Wollaston, to express the system of definite ratios, in which the corpuscular objects of this science reciprocally combine, referred to a common standard, reckoned unity. See *Atomic system*.

E′QUUS. 1. The horse.

2. The name of a genus of animals of the order *Belluæ*.

Equus asinus. The systematic name of the animal called an ass; the female affords a light and nutritious milk. See *Milk asses'*.

Era′nthemus. (From ηρ, the spring, and ανθεμος, a flower: so called because it flowers in the spring.) A sort of chamomile.

ERASIS′TRATUS. A celebrated Greek physician, said to have been born in the island of Ceos, and to have been the most distinguished pupil of Chrysippus, of the Cnidian school. He was the first, in conjunction with Herophilus, to dissect human bodies, anatomy having been before studied only in brutes; but the Ptolemies having allowed them to examine malefactors, they were enabled to make many important discoveries. Celsus notices a very improbable report, that they opened the bodies of those persons alive, to observe the internal motions: they could hardly then have maintained, that the arteries and left ventricle, do not naturally contain blood, but air only. The works of Erasistratus, which were numerous, are lost; but, from the account of Galen, he appears to have very accurately described the brain, which he considered as the common sensorium; also the heart and large vessels; and pointed out the office of the liver and kidneys; but he supposed digestion performed by trituration. He imagined inflammation and fever to arise from the blood being forced through the minute veins into the corresponding arteries. He was averse from blood-letting, or the use of active medicines, but sometimes employed mild clysters; trusting, however, principally to abstinence, and proper exercise. Being tormented with an ulcer in the foot, at an extreme old age, he is said to have terminated his existence by poison.

Erate′va marmelos. This plant, a native of several parts of India, affords a fruit about the size of an orange, and covered with a hard bony shell, containing a yellow viscus pulp, of a most agreeable flavour; which, when scooped out, and mixed with sugar and orange, is brought to the tables of the grandees in India, who eat it as a great delicacy. It is also esteemed as a sovereign remedy against dysentery.

EREBI′NTHUS. Ερεβινθος. The vetch.

ERE′CTOR. The name of several muscles, the office of which is to raise up the part to which they are inserted.

ERECTOR CLITORIDIS. First muscle of the clitoris of Douglas. *Ischio-cavernosus* of Winslow, and *Ischio-clitoridien* of Dumas. A muscle of the clitoris that draws it downwards and backwards, and serves to make the body of the clitoris more tense, by squeezing the blood into it from its crus. It arises from the tuberosity of the ischium, and is inserted into the clitoris.

ERECTOR PENIS. *Ischio-cavernosus* of Winslow, and *Ischio-caverneux* of Dumas. A muscle of the penis that drives the urine or semen forwards, and, by grasping the bulb of the urethra, pushes the blood towards the corpus cavernosum and the glans, and thus distends them. It arises from the tuberosity of the ischium, and is inserted into the sides of the cavernous substance of the penis.

ERECTUS. Upright. Botanists use this to express the direction of the stem, branches, leaves, petals, stamens, pistills, &c.; as *Caulis erectus*, an upright stem, as in *Lysimachia vulgaris*; *folium erectum* forming an acute angle with the stem, as in *Juncus articulatus*, &c. The petals of the *Brassica erecta*.

ERETHI′SMUS. (From ερεθιζω, to excite or irritate.) Increased sensibility and irritability. It is variously applied by modern writers. Mr. Pearson has described a state of the constitution produced by mercury acting on it as a poison. He calls it the mercurial erithismus, and mentions that it is characterised by great depression of strength, anxiety about the præcordia, irregular action of the heart, frequent sighing, trembling, a small, quick, sometimes intermitting pulse, occasional vomiting, a pale contracted countenance, a sense of coldness; but the tongue is seldom furred, nor are the vital and natural functions much disturbed. In this state any sudden exertion will sometimes prove fatal.

ERGASTE′RIUM. (From εργον, work.) A laboratory: that part of the furnace in which is contained the matter to be acted upon.

ERI′CA. (From ερεικω, to break; so named from its fragility, or because it is broken into rods to make besoms of.) The name of a genus of plants in the Linnæan system. Class, *Octandria*; Order, *Monogynia*. Heath.

ERICE′RUM. (From ερεικη, heath.) A medicine in which heath is an ingredient.

ERI′GERON. (Ηριγερων, of the ancient Greeks; from ηρ, the spring, and γερων, an old man, because, in the spring, it has a white, hoary blossom, like the hair of an old man.) 1. The name of a genus of plants. Class, *Syngenesia*; Order, *Polygamia superflua*.

2. The common chick-weed is so called in old books. See *Senecio vulgaris*.

ERIGERUM. See *Senecio vulgaris*.

ERO′SION. (*Erosio*; from *erodo*, to gnaw off.) This word is very often used in the same sense as ulceration, viz. the formation of a breach or chasm in the substance of parts, by the action of the absorbents.

EROSUS. Jagged. A leaf is called *folium erosum*, the margin of which is irregularly cut or notched, especially when otherwise divided besides; as in *Senecio squalidus*.

EROTIA′NUS, the author of a Glossary, containing an explanation of the terms in Hippocrates, lived in the reign of Nero. The work was printed at Venice, in 1566; and also annexed to Foësius's Edition of Hippocrates.

EROTOMA′NIA. (From ερως, love, and μανια, madness.) That melancholy, or madness, which is the effect of love.

E′RPES. (From ερπω, to creep: so named from their gradually increasing in size.) See *Herpes*.

ERRA′TIC. (*Erraticus*; from *erro*, to wander.) Wandering; irregular. A term occasionally applied to pains, or any disease which is not fixed, but moves from one part to another, as gout, rheumatism, &c.

E′RRHINE. (*Errhinus*; ερρινα, from εν, in, and ριν, the nose.) By errhines are to be understood those medicines which, when topically applied to the internal membrane of the nose, excite sneezing, and increase the secretion, independent of any mechanical irritation. The articles belonging to this class may be referred to two orders.

1. *Sternutatory errhines*; as *nicotiana*, *helleborus*, *euphorbium*, which are selected for the torpid, the vigorous, but not plethoric, and those to whom any degree of evacuation would not be hurtful.

2. *Evacuating errhines*; as *asarum*, &c. which are calculated for the phlegmatic and infirm.

E′RROR LOCI. Boerhaave is said to have introduced this term, from the opinion that the vessels were of different sizes, for the circulation of blood, lymph, and serum, and that when the larger sized globules were forced into the lesser vessels, they became obstructed, by an *error of place*. But this opinion does not appear to be well-grounded.

ERU′CA. (From *erugo*, to make smooth; so named from the smoothness of its leaves, or from *uro*, to burn, because of its biting quality.) See *Brassica eruca*.

ERUCA SYL′VESTRIS. The wild rocket. See *Brassica eruca*.

ERUCTATION. Belching.

ERUPTION. *Eruptio*. A discoloration, or spots on the skin; as the eruption of small-pox, measels, nettle-rash, &c.

ERUTHEMA. (From ερυθω, to make red.) A fiery red tumour, or pustules on the skin.

E′RVUM. (*Quasi arvum*, a field, because it grows wild in the fields; or from *eruo*, to pluck out, because it is diligently plucked from corn.) The tare. 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria*.

2. The pharmacopœial name of tare. See *Ervum ervilia*.

ERVUM ERVILIA. *Orobus*. The seeds of this plant, *Ervum ervilia—germinibus undatoplicatis, foliis imparipinnatis* of Linnæus, have been made into bread in times of scarcity, which is not the most salubrious. The meal was formerly among the resolvent remedies by way of poultice.

ERVUM LENS. The systematic name of the lentil. *Lens*. Φακος of the Greeks. *Ervum—pedunculis subbifloris; seminibus compressis, convexis*, of Linnæus. There are two varieties; the one with large, the other small seeds. They are eaten in many places as we eat peas, than which they are more flatulent, and more difficult to digest. A decoction of these seeds is used as a lotion to the ulcerations after small-pox, and, it is said, with success.

ERY′NGIUM. (From ερυγγανω, to eructate.) Eryngo, or sea-holly. 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia*.

2. The pharmacopœial name of the sea-holly. See *Eryngium maritimum*.

ERYNGIUM CAMPESTRE. The root of this plant, *Eryngium—foliis radicalibus, amplexicaulibus, pinnato-lanceolatis*, of Linnæus, is used in many places for that of the sea-eryngo. See *Eryngium*.

ERYNGIUM MARITIMUM. The systematic name of the sea-holly or eryngo. *Eryngium—foliis radicalibus subrotundis, plicatis spinosis, capitulis pedunculatis, paleis tricuspidatis*, of Linnæus. The root of this plant is directed for medicinal use. It has no particular smell, but to the taste it manifests a grateful sweetness; and, on being chewed for some time, it discovers a light aromatic warmth or pungency. It was formerly celebrated for its supposed aphrodisiac powers, but it is now very rarely employed.

ERYNGO. See *Eryngium*.

Eryngo, sea. See *Eryngium*.

Eryngo-leaved-lichen. See *Lichen islandicus*.

ERY'SIMUM. (From ερυω, to draw, so called from its power of drawing and producing blisters. Others derive it απο του ερεικειν, because the leaves are much cut; others from εριτιμον, precious.) 1. The name of a genus of plants in the Linnæan system. Class, *Tetradynamia*; Order, *Siliquosa*.

2. The pharmacopœial name of the hedge mustard. See *Erysimum officinale*.

ERYSIMUM ALLIARIA. The systematic name of Jack in the hedge. *Alliaria*; *Chamæplion* of Oribasius. Sauce alone, or stinking hedge-mustard. The plant to which this name is given, is the *Erysimum foliis cordatis*, of Linnæus; it is sometimes exhibited in humid asthma and dyspnœa, with success. Its virtues are powerfully diaphoretic, diuretic, and antiscorbutic.

ERYSIMUM BARBAREA. The systematic name of the *barbarea* of the shops. The leaves of this plant, *Erysimum—foliis lyratis, extimo subrotundo* of Linnæus, may be ranked among the antiscorbutics. They are seldom used in practice.

ERYSIMUM OFFICINALE. The systematic name of the hedge-mustard. *Erysimum—siliquis spicæ adpressis, foliis runcinatis*, of Linnæus. It was formerly much used for its expectorant and diuretic qualities, which are now forgotten. The seeds are warm and pungent, and very similar to those of mustard in their sensible effects.

ERYSI'PELAS. (From ερυω, to draw, and ϖελας, adjoining: named from the neighbouring parts being affected by the eruption.) *Ignis sacer*. The rose, or St. Anthony's fire. A genus of disease in the class *Pyrexiæ*, and order *Exanthemata* of Cullen. It is known by cynocha of two or three days' continuance, with drowsiness, and sometimes with delirium; pulse commonly full and hard; then erythema of the face, or some other part, with continuance of synocha, tending either to abscess or gangrene. There are two species of this disease, according to Cullen: 1. *Erysipelas vesiculosum*, with large blisters: 2. *Erysipelas phlyctænodes*, the shingles, or an erypelas with phlyctænæ, or small blisters.

This disease is an inflammatory affection, principally of the skin, when it makes its appearance externally, and of the mucous membrane when it is seated internally; and is more liable to attack women and children, and those of an irritable habit, than those of a plethoric and robust constitution.

It is remarkable that erysipelas sometimes returns periodically, attacking the patient once or twice a year, or even once every month, and then by its repeated attacks it often gradually exhausts the strength, especially if he be old and of a bad habit.

When the inflammation is principally confined to the skin, and is unattended by any affection of the system, it is then called erythema; but when the system is affected, it is named erysipelas.

Every part of the body is equally liable to it, but it more frequently appears on the face, legs, and feet, than any where else when seated externally; and it occurs oftener in warm climates than phlegmonous inflammation.

It is brought on by all the causes that are apt to excite inflammation, such as injuries of all kinds, the external application of stimulants, exposure to cold, and obstructed perspiration; and it may likewise be occasioned by a certain matter generated within the body, and thrown out on its surface. A particular state of the atmosphere seems sometimes to render it epidemical.

In slight cases, where it attacks the extremities, it makes its appearance with a roughness, heat, pain, and redness of the skin, which becomes pale when the finger is pressed upon it, and again returns to its former colour, when it is removed. There prevails likewise a small febrile disposition, and the patient is rather hot and thirsty. If the attack is mild, these symptoms will continue only for a few days, the surface of the part affected will become yellow, the cuticle or scarf-skin will fall off in scales, and no further inconvenience will perhaps be experienced; but if the attack has been severe, and the inflammatory symptoms have run high, then there will ensue pains in the head and back, great heat, thirst, and restlessness; the part affected will slightly swell: the pulse will become small and frequent; and about the fourth day, a number of little vesicles, containing a limpid, and, in some cases a yellowish fluid, will arise. In some instances, the fluid is viscid, and instead of running out, as generally happens when the blister is broken, it adheres to and dries upon the skin.

In unfavourable cases, these blisters sometimes degenerate into obstinate ulcers, which now and then become gangrenous. This, however, does not happen frequently; for although it is not uncommon for the surface of the skin, and the blistered places to appear lived or even blackish, yet this usually disappears with the other symptoms.

The period at which the vesicles show themselves is very uncertain. The same may be said of the duration of the eruption. In mild cases, it often disappears gradually, or is carried off by spontaneous sweating. In some cases it continues without showing any disposition to decline for twelve or fourteen days, or longer.

The trunk of the body is sometimes attacked with erysipelatous inflammation, but less frequently so than the extremities. It is not uncommon, however, for infants to be attacked in this manner a few days after birth; and in these it makes its appearance about the genitals. The inflamed skin is hard, and apparently very painful to the touch. The belly often becomes uniformly tense, and sphacelated spots sometimes are to be observed. From dissections made by Dr. Underwood, it appears, that in this form of the disease the inflammation frequently spreads to the abdominal viscera.

Another species of erysipelatous inflammation, which most usually attacks the trunk of the body, is that vulgarly known by the name of *shingles*, being a corruption of the French word *ceingle*, which implies a belt. Instead of appearing an uniform inflamed surface, it consists of a number of little pimples extending round the body a little above the umbilicus, which have vesicles formed on them in a short time. Little or no danger ever attends this species of erysipelas.

When erysipelas attacks the face, it comes on with chilliness, succeeded by heat, restlessness, thirst, and other febrile symptoms, with a drowsiness or tendency to coma or delirium, and the pulse is very frequent and full. At the end of two or three days, a fiery redness appears on some part of the face, and this extends at length to the scalp, and then gradually down the neck, leaving a tumefaction in every part the redness has occupied. The whole face at length becomes turgid, and the eyelids are so much swelled as to deprive the patient of sight. When the redness and swelling have continued for some time, blisters of different sizes, containing a thin colourless acrid liquor, arise on different parts of the face, and the skin puts on a livid appearance in the blistered places; but in those not affected with blisters, the cuticle, towards the close of the disease, falls off in scales.

No remission of the fever takes place on the appearance of the inflammation on the face; but, on the contrary, it is increased as the latter extends, and both will continue probably for the space of eight or ten days. In the course of the inflammation, the disposition to coma and delirium are sometimes so increased as to destroy the patient between the seventh and eleventh days of the disease. When the complaint is mild, and not leading to a fatal event, the inflammation and fever generally cease gradually without any evident crisis.

If the disease arises in a bad habit of body, occupies a part possessed of great sensibility, is accompanied with much inflammation, fever, and delirium, and these take place at an early period, we may suppose the patient exposed to imminent danger. Where translations of the morbid matter take place, and the inflammation falls on either the brain, lungs, or abdominal viscera, we may entertain the same unfavourable opinion. Erysipelas never terminates in suppuration, unless combined with a considerable degree of phlegmonous inflammation, which is, however, sometimes the case; but in a bad habit, it is apt to terminate in gangrene, in which case there will be also great danger. When the febrile symptoms are mild, and unaccompanied by delirium or coma, and the inflammation does not run high, we need not be apprehensive of danger.

Where the disease has occupied the face, and proves fatal, inflammation of the brain, and its consequences, are in some cases met with on dissection.

The treatment of erysipelas must proceed on the antiphlogistic plan, varied however in its activity according to the type of the disease. When it occurs in robust plethoric constitutions, partaking of the phlegmonous character, with severe synochal fever, it will be proper to begin by taking a moderate quantity of blood; then direct cooling saline purgatives, antimonial diaphoretics, a light vegetable diet, &c. When the disorder attacks the face, it may be better to use cupping behind the neck, and keep the head somewhat raised. But if the disease exhibits rather the typhoid type, and particularly where there is a tendency to gangrene, the patient's strength must be supported: after clearing out the primæ viæ, and endeavouring to promote the other secretions by mild evacuants, when the pulse begins to fail, a more nutritious diet, with a moderate quantity of wine, and the decoction of bark with sulphuric acid, or other tonic medicine, may be resorted to; nay, even the bark in substance, and the more powerful stimulants, as ammonia, &c. ought to be tried, if the preceding fail. Should the inflammation quitting the skin, attack an internal part, a blister, or some rubefacient, may help to relieve the patient; and stimulants to the lower extremities will likewise be proper, where the head is severely affected. To the inflamed part of the skin applications must not be too freely made: where there is much pain and heat, cooling it occasionally with plain water, is perhaps best; and where an acrid discharge occurs, washing it away from time to time with warm milk and water. Should suppuration happen it is important to make an early opening for the escape of the matter, to obviate the extensive sloughings otherwise apt to follow, and where gangrene occurs, the fermenting cataplasm may be applied.

ERYTHE'MA. (From ερυθρος, red.) Inflammatory blush. A morbid redness of the skin, as is observed upon the cheeks of hectic patients after eating, and the skin covering bubo, phlegmon, &c.

ERYTHRO'DANUM. (From ερυθρος, red: so called from the colour of its juice.) See *Rubia tinctorum.*

ERYTHROEI'DES. (From ερυθρος, red, and ειδος, a likeness: so called from its colour.) A name given to the tunica vaginalis testis.

ERYTHRO'NIUM. (From ερυθρος, red: so called from the red colour of its juice.) A species of satyrion.

ERYTHRO'XYLUM. (From ερυθρος, red, and ξυλον, wood: so named from its colour.) Logwood. See *Hæmatoxylum.*

E'RYTHRUS. (From ερυθρος, red: so named from the red colour of its juice.) The sumach. See *Rhus coriaria.*

E'SAPHE. (From εσαφαω, to feel.) The touch; or feeling the mouth of the womb, to ascertain its condition.

E'SCHAR. (Εσχαρα; from εσχαροω, to scab over.) *Eschara.* The portion of flesh that is destroyed by the application of a caustic, and which sloughs away.

ESCHARO'TIC. (*Escharoticus;* from εσχαροω, to scab over.) Caustic; Corrosive. A term given by surgeons to those substances which possess a power of destroying the texture of the various solid parts of the animal body to which they are directly applied. The articles of this class of substances may be arranged under two orders:

1. *Eroding escharotics;* as blue vitriol, *alumen ustum,* &c.

2. *Caustic escharotics;* as *lapis infernalis, argenti nitras, acidum sulphuricum, nitricum,* &c.

ESCULENT. *Esculentus.* An appellation given to such animals, fishes, and plants, or any part of them, that may be eaten for food.

E'SOX. The name of a genus of fishes. Class, *Pisces;* Order, *Abdominales.*

ESOX LUCIUS. The systematic name of the pike fish, from the liver of which an oil is separated spontaneously, which is termed in some pharmacopœias *oleum lucii piscis.* It is used in some countries by surgeons, to destroy spots of the transparent cornea.

E'SSENCE. Several of the volatile or essential oils are called by this name.

ESSENTIAL. *Essentialis.* Something that is necessary to constitute a thing, or that has such a connexion with the nature of a thing, that it found wherever the thing itself is: thus the heart, brain, spinal marrow, lungs, stomach, &c. are parts essential to life.

In natural history it is applied to those circumstances which mark or distinguish an animal or plant from all others in the same order or genus.

ESSE'NTIAL OIL. See *Oil.*

E'SSERA. (*Essera*, from *Eshera*, an Arabian word literally meaning *papulæ.*) A species of cutaneous eruption, distinguished by broad, shining, smooth, red spots, mostly without fever, and differing from the nettle rash in not being elevated. It generally attacks the face and hands.

ESTHIOMENOS. (From εσθιω, to eat.) A term formerly applied to any disease which rapidly destroyed, or as it were ate away the flesh, as some forms of herpes, lupus, cancer.

E'SULA. (From *esus*, eaten, because it is eaten by some as a medicine.) Spurge.

ESULA MAJOR. See *Euphorbia palustris.*

ESULA MINOR. See *Euphorbia cyparissias.*

E'THER. See *Æther.*

ETHER, ACETIC. Acetic naphtha. An etherial fluid, drawn over from an equal admixture of alkohol and acetic acid, distilled with a gentle heat from a glass retort in a sand-bath. It has a grateful smell, is extremely light, volatile, and inflammable.

ETHER, MURIATIC. Marine æther. Muriatic æther is obtained by mixing and distilling alkohol with extremely concentrated muriate of tin. It is stimulant, antiseptic, and diuretic.

ETHER, NITROUS. Nitric naphtha. This is only a stronger preparation than the spiritus ætheris nitrici of the London Pharmacopœia; it is produced by the distillation of two parts of alkohol to one part and a half of fuming nitric acid.

ETHER, SULPHURIC. See *Æther sulphuricus.*

ETHER, VITRIOLIC. See *Æther sulphuricus.*

ETHERIAL. A term applied to any highly rectified essential oil, or spirit. See *Oleum æthereum.*

Ethiops, antimonial. See *Æthiops antimonialis.*

Ethiops, martial. The black oxide of iron.

Ethiops, mineral. See *Hydrargyri sulphuretum nigrum.*

Ethiops per se. See *Hydrargyri oxydum cinereum.*

ETHMOID. (*Ethmoides*; from εθμος, a sieve, and ειδος, form: because it is perforated like a sieve.) Sieve-like.

ETHMOID BONE. *Os ethmoideum; os æthmoides.* Cribriform bone. A bone of the head. This is, perhaps, one of the most curious bones of the human body. It appears almost a cube, not of solid bone, but exceedingly light, spongy, and consisting of many convoluted plates, which form a net-work, like honey-comb. It is curiously enclosed in the os frontis, betwixt the orbitary processes of that bone. One horizontal plate receives the olfactory nerves, which perforate that plate with such a number of small holes, that it resembles a sieve; whence the bone is named cribriform, or ethmoid bone. Other plates dropping perpendicularly from this one, receive the divided nerves, and give them an opportunity of expanding into the organ of smelling; and these bones, upon which the olfactory nerves are spread out, are so much convoluted as to extend the surface of this sense very greatly, and are named spongy bones. Another flat plate lies in the orbit of the eye; and being very smooth, by the rolling of the eye it is named the os planum, or smooth bone. So that the ethmoid bone supports the forepart of the brain, receives the olfactory nerves, forms the organ of smelling, and makes the chief part of the orbit of the eye; and the spongy bones, and the os planum, are neither of them distinct bones, but parts of this ethmoid bone.

The *cribriform plate* is exceedingly delicate and thin; lies horizontally over the root of the nose; and fills up neatly the space betwixt the two orbitary plates of the frontal-bone. The olfactory nerves, like two small flat lobes, lie out upon this plate, and, adhering to it, shoot down like many roots through this bone, so as to perforate it with numerous small holes, as if it had been dotted with the point of a pin, or like a nutmeg-grater. This plate is horizontal; but its processes are perpendicular, one above, and three below.

1. The first perpendicular process is what is called *crista galli;* a small perpendicular projection, somewhat like a cock's comb, but exceedingly small, standing directly upwards from the middle of the cribriform plate, and dividing that plate into two; so that one olfactory nerve lies upon each side of the crista galli; and the root of the falx, or septum, betwixt the two hemispheres of the brain, begins from this process. The foramen cæcum, or blind hole of the frontal bone, is formed partly by the root of the crista galli, which is very smooth, and sometimes, it is said, hollow, or cellular.

2. Exactly opposite this, and in the same direction with it, *i. e.* perpendicular to the ethmoid plate, stands out the *nasal plate* of the ethmoid bone. It is sometimes called azygous, or single process of the ethmoid, and forms the beginning of that septum, or partition, which divides the two nostrils. This process is thin but firm, and composed of solid bone; it is commonly inclined a little to one side, so as to make the nostrils of unequal size. The azygous process is united with the vomer, which forms the chief part of the partition; so that the septum, or partition of the nose, consists of the azygous process of the ethmoid bone above, of the vomer below, and of the cartilage in the fore or projecting part of the nose; but the cartilage rots away, so that whatever is seen of the septum in the skull must be part either of the ethmoid bone or vomer.

3. Upon either side of the septum, there hangs down a *spongy bone*, one hanging in each nostril. They are each rolled up like a scroll of parchment; they are very spongy; are covered with a delicate and sensible membrane: and when the olfactory nerves depart from the cribriform plate of the ethmoid bone, they attach themselves to the septum, and to these upper spongy bones, and expand upon them so that the convolutions of these bones are of material use in expanding the organ of swelling, and detaining the odorous effluvia till the impression be perfect. Their convolutions are more numerous in the lower animals, in proportion as they need a more acute sense. They are named spongy or turbinated bones, from their convolutions resembling the many folds of a turban.

The spongy bones have a great many honeycomb-like cells connected with them, which belong also to the organ of smell, and which are useful perhaps by detaining the effluvia of odorous bodies, and also by reverberating the voice. Thus, in a common cold, while the voice is hurt by an affection of these cells, the sense of smelling is almost lost.

4. The *orbitary plate*, of the ethmoid bone, is a large surface; consisting of a very firm plate

of bone, of a regular square form: exceedingly smooth and polished; it forms a great part of the socket for the eye, lying on its inner side. When we see it in the detached bone, we know it to be just the flat side of the ethmoid bone; but while it is incased in the socket of the eye, we should believe it to be a small square bone: and from this, and from its smoothness, it has got the distinct name of os planum.

The cells of the ethmoid bone, which form so important a share of the organ of smell, are arranged in great numbers along the spongy bone. They are small neat cells, much like a honeycomb, and regularly arranged in two rows, parted from each other by a thin partition; so that the os planum seems to have one set of cells attached to it, while another regular set of cells belongs in like manner to the spongy bones. There are thus twelve in number opening into each other, and into the nose.

These cells are frequently the seat of venereal ulcers; and the spongy bones are the surface where polypi often sprout up. And from the general connections and forms of the bone, we can easily understand how the venereal ulcer, when deep in the nose, having got to these cells, cannot be cured, but undermines all the face; how the venereal disease, having affected the nose, soon spreads to the eye, and how even the brain itself is not safe. We see the danger of a blow upon the nose, which, by a force upon the septum, or middle partition, may depress the delicate cribriform plate, so as to oppress the brain with all the effects of a fractured skull, and without any operation which can give relief. And we also see the danger of pulling away polypi, which are firmly attached to the upper spongy bone.

ETHMOI'DES. See *Ethmoid bone.*

ETMULLER, Michael, was born at Leipsic, in 1644. He graduated there at the age of twenty-four, after going through the requisite studies, and much improving himself by travelling through different parts of Europe. Eight years after he was appointed professor of botany in that University, as well as extraordinary professor of surgery and anatomy. He fulfilled those offices with great applause, and his death, which happened in 1683, was generally regretted by the faculty of Leipsic. He was a very voluminous writer, and his works were considered to have sufficient merit to be translated into most European languages.

E'tron. (From εδω, to eat, as containing the receptacles of the food.) The hypogastrium.

Eua'nthemum. (From ευ, well, and ανθεμος, a flower: so named from the beauty of its flowers.) The chamomile.

Eua'phium. (From ευ, wel, and αφη, the touch: so called because its touch was supposed to give ease.) A medicine for the piles.

EUCHLORINE. See *Chlorous oxide.*

Euclase. The prismatic emerald.

Eudialite. A brownish red-coloured mineral, belonging to the tessular system of Molis.

EUDIO'METER. An instrument by which the quantity of oxygen and nitrogen in atmospherical air can be ascertained. Several methods have been employed, all founded upon the principle of decomposing common air by means of a body which has a greater affinity for the oxygen. See *Eudiometry.*

EUDIOMETRY. The method of ascertaining the purity of atmospheric air.

No sooner was the composition of the atmosphere known, than it became an inquiry of importance to find out a method of ascertaining, with facility and precision, the relative quantity of oxygen gas contained in a given bulk of atmospheric air.

The instruments in which the oxygen gas of a determined quantity of air was ascertained, received the name of *Eudiometers*, because they were considered as measurers of the purity of air. They are, however, more properly called *Oximeters.*

The eudiometers proposed by different chemists, are the following:

1. *Priestley's Eudiometer.*—The first eudiometer was made in consequence of Dr. Priestley's discovery, that when nitrous gas is mixed with atmospheric air over water, the bulk of the mixture diminishes rapidly, in consequence of the combination of the gas with the oxygen of the air, and the absorption of the nitric acid thus formed by the water.

When nitrous gas is mixed with nitrogen gas, no diminution takes place; but when it is mixed with oxygen gas, in proper proportions, the absorption is complete. Hence it is evident, that in all cases of a mixture of these two gases, the diminution will be proportional to the quantity of the oxygen. Of course it will indicate the proportion of oxygen in air; and by mixing it with different portions of air, it will indicate the different quantities of oxygen which they contain, provided the component parts of air be susceptible of variation.

Dr. Priestley's method was to mix together equal bulks of air and nitrous gas in a low jar, and then transfer the mixture into a narrow graduated glass tube about three feet long, in order to measure the diminution of bulk. He expressed this diminution by the number of hundredth parts remaining. Thus, suppose he had mixed together equal parts of nitrous gas and air, and that the sum total was 200 (or 2.00:) suppose the residuum, when measured in the graduated tube, to amount to 104 (or 1.04,) and of course that 96 parts of the whole had disappeared, he denoted the purity of the air thus tried by 104.

This method of analysing air by means of nitrous gas is liable to many errors. For the water over which the experiment is made may contain more or less carbonic acid, atmospheric air, or other heterogeneous substance. The nitrous gas is not always of the same purity, and is partly absorbed by the nitrous acid which is formed; the figure of the vessel, and many other circumstances are capable of occasioning considerable differences in the results.

Fontana, Cavendish, Ladriani, Magellan, Von Humboldt, and Dr. Falconer, have made series of laborious experiments to bring the test of nitrous gas to a state of complete accuracy; but, notwithstanding the exertions of these philosophers, the methods of analysing air by means of nitrous gas are liable to so many anomalies, that it is unnecessary to give a particular description of the different instruments invented by them.

2. *Scheele's Eudiometer.*—This is merely a graduated glass cylinder, containing a given quantity of air, exposed to a mixture of iron filings and sulphur, formed into a paste with water. The substances may be made use of in the following manner:

Make a quantity of sulphur in powder, and iron filings, into a paste with water, and place the mixture in a saucer, or plate, over water, on a stand raised above the fluid; then invert over it a graduated bell-glass, and allow this to stand for a few days. The air contained in the bell-glass will gradually diminish, as will appear from the ascent of the water.

When no further diminution takes place, the vessel containing the sulphuret must be removed, and the remaining air will be found to be nitrogen gas, which was contained in that quantity of atmospheric air.

In this process, the moistened sulphuret of iron has a great affinity to oxygen; it attracts and separates it from the atmospheric air, and the nitrogen gas is left behind; the sulphur, during the experiment, is converted into sulphuric acid, and the iron oxidised, and sulphate of iron results.

The air which is exposed to moistened iron and sulphur, gradually becomes diminished, on account of its oxygen combining with a portion of the sulphur and iron, while its nitrogen remains behind. The quantity of oxygen contained in the air examined becomes thus obvious, by the diminution of bulk, which the volume of air submitted to examination, has undergone.

A material error to which this method is liable, is that the sulphuric acid which is formed, acts partly on the iron, and produces hydrogen gas, which joins to some of the nitrogen forming ammonia; and hence it is that the absorption amounts in general to 0.27 parts, although the true quantity of oxygen is no more than from 0.21 to 0.22.

3. *De Marti's Eudiometer.*—De Marti obviated the errors to which the method of Scheele was liable. He availed himself, for that purpose, of a hydroguretted sulphuret, formed by boiling sulphur and liquid potassa, or lime water, together. These substances, when newly prepared, have the property of absorbing a minute portion of nitrogen gas; but they lose this property when saturated with that gas, which is easily effected by agitating them for a few minutes in contact with a small portion of atmospheric air.

The apparatus is merely a glass tube, ten inches long, and rather less than half an inch in diameter, open at one end, and hermetically sealed at the other. The close end is divided into one hundred equal parts, having an interval of one line between each division. The use of this tube is to measure the portion of air to be employed in the experiment. The tube is filled with water; and by allowing the water to run out gradually, while the tube is inverted, and the open end kept shut with the finger, the graduated part is exactly filled with air. These hundred parts of air are introduced into a glass bottle, filled with liquid sulphuret of lime previously saturated with nitrogen gas, and capable of holding from two to four times the bulk of the air introduced. The bottle is then to be closed with a ground glass stopper, and agitated for five minutes. After this, the stopper is to be withdrawn, while the mouth of the phial is under water; and, for the greater accuracy, it may be closed and agitated again. Lastly, the air is to be again transferred to the graduated glass tube, in order to ascertain the diminution of its bulk.

4. *Humboldt's Eudiometer*—Consists in decomposing a definite quantity of atmospheric air, by means of the combustion of phosphorus, after which, the portion of gas which remains must be measured.

Take a glass cylinder, closed at the top, and whose capacity must be measured into sufficiently small portions by a graduated scale fixed on it. If the instrument be destined solely for examining atmospheric air, it will be sufficient to apply the scale from the orifice of the cylinder down to about half its length, or to sketch that scale on a slip of paper pasted on the outside of the tube, and to varnish it over with a transparent varnish.

This half of the eudiometrical tube is divided into fifty equidistant parts, which in this case indicate hundredth parts of the whole capacity of the instrument.

Into this vessel, full of atmospheric air, put a piece of dry phosphorus (one grain to every twelve cubic inches,) close it air-tight, and heat it gradually, first the sides near the bottom, and afterwards the bottom itself. The phosphorus will take fire and burn rapidly. After every thing is cold, invert the mouth of the eudiometer-tube into a basin of water, and withdraw the cork. The water will ascend in proportion to the loss of oxygen gas the air has sustained, and thus its quantity may be ascertained.

Analogous to this is,

5. *Seguin's Eudiometer,*—which consists of a glass tube, of about one inch in diameter, and eight or ten inches high, closed at the upper extremity. It is filled with mercury, and kept inverted in this fluid in the mercurial trough. A small bit of phosphorus is introduced into it, which on account of its specific gravity being less than that of mercury, will rise up in it to the top. The phosphorus is then melted by means of a red-hot poker, or burning coal applied to the outside of the tube. When the phosphorus is liquefied, small portions of air destined to be examined, and which have been previously measured in a vessel graduated to the cubic inch, or into grains, are introduced into the tube. As soon as the air which is sent up reaches the phosphorus, a combustion will take place, and the mercury will rise again. The combustion continues till the end of the operation; but, for the greater exactness, Seguin directs the residuum to be heated strongly. When cold, it is introduced into the graduated vessel to ascertain its volume. The difference of the two volumes gives the quantity of the oxygen gas contained in the air subjected to examination.

6. *Berthollet's Eudiometer.*—Instead of the rapid combustion of phosphorus, Berthollet has substituted its spontaneous combustion, which absorbs the oxygen of atmospheric air completely; and, when the quantity of air operated on is small, the process is accomplished in a short time.

Berthollet's apparatus consists of a narrow graduated glass tube, containing the air to be examined, into which is introduced a cylinder, or stick of phosphorus, supported upon a glass rod, while the tube stands inverted in water. The phosphorus should be nearly as long as the tube. Immediately after the introduction of the phosphorus, white vapours are formed which fill the tube; these vapours gradually descend, and become absorbed by the water. When no more white vapours appear, the process is at an end, for all the oxygen gas which was present in the confined quantity of air, has united with the phosphorus; the residuum is the quantity of nitrogen of the air submitted to examination.

This eudiometer, though excellent of the kind, is nevertheless not absolutely to be depended upon; for, as soon as the absorption of oxygen is completed the nitrogen gas exercises an action upon the phosphorus, and thus its bulk becomes increased. It has been ascertained, that the volume of nitrogen gas is increased by 1-40th part; consequently the bulk of the residuum, diminished by 1-40, gives us the bulk of the nitrogen gas of the air examined; which bulk subtracted from the original mass of air, gives us the proportion of oxygen gas contained in it. The same allowance must be made in the eudiometer of Seguin.

7. *Davy's Eudiometer.* Until very lately, the preceding processes were the methods of deter-

mining the relative proportions of the two gases which compose our atmosphere.

Some of these methods, though very ingenious, are so extremely slow in their action, that it is difficult to ascertain the precise time at which the operation ceases. Others have frequently involved inaccuracies, not easily removed.

The eudiometer of Davy is not only free from these objections, but the result it offers is always constant; it requires little address, and is very expeditious; the apparatus is portable, simple, and convenient.

Take a small glass tube, graduated into one hundred equi-distant parts; fill this tube with the air to be examined, and plunge it into a bottle, or any other convenient vessel, containing a concentrated solution of green muriate or sulphate of iron, strongly impregnated with nitrous gas. All that is necessary to be done, is to move the tube in the solution a little backwards and forwards; under these circumstances, the oxygen gas contained in the air will be rapidly absorbed, and condensed by the nitrous gas in the solution, in the form of nitrous acid.

N. B. The state of the greatest absorption should be marked, as the mixture afterwards emits a little gas which would alter the result.

This circumstance depends upon the slow decomposition of the nitrous acid (formed during the experiment,) by the oxide of iron, and the consequent production of a small quantity of aëriform fluid (chiefly nitrous gas;) which, having no affinity with the red muriate, or sulphate of iron, produced by the combination of oxygen, is gradually evolved and mingled with the residual nitrogen gas. However, the nitrous gas evolved might be abstracted by exposing the residuum to a fresh solution of green sulphate or muriate of iron.

The impregnated solution with green muriate, is more rapid in its operation than the solution with green sulphate. In cases when these salts cannot be obtained in a state of absolute purity, the common sulphate of iron of commerce may be employed. One cubic inch of moderately impregnated solution, is capable of absorbing five or six cubic inches of oxygen, in common processes; but the same quantity must never be employed for more than one experiment.

In all these different methods of analysing air, it is necessary to operate on air of a determinate density, and to take care that the residuum be neither more condensed nor dilated than the air was when first operated on. If these things are not attended to, no dependence whatever can be placed upon the result of the experiments, how carefully soever they may have been performed. It is, therefore, necessary to place the air, before and after the examination, into water of the same temperature. If this, and several other little circumstances, have been attended to, for instance, a change in the height of the barometer, &c. we find that air is composed of about 0.21 of oxygen gas, and 0.79 of nitrogen gas by bulk. But as the weight of these two gases is not exactly the same, the proportion of the component parts by weight will differ a little; for as the specific gravity of oxygen gas is to that of nitrogen gas as 8 to 7 nearly, it follows that 100 parts of air are composed *by weight* of about 76 nitrogen gas, and 24 oxygen gas.

The air of this metropolis, examined by means of Davy's eudiometer, was found, in all the different seasons of the year to contain 0.21 of oxygen; and the same was the case with air taken at Islington and High-gate; in the solitary cells in Cold-Bath-Fields prison, and on the river Thames. But the quantity of water contained in a given bulk of air from these places, differed considerably.

EUGALENUS, Severinus, a physician of Doccum, in Friesland, known chiefly as the author of a Treatise on the Scurvy, in 1604, which once maintained a considerable character; but the publication of Dr. Lind, pointing out his numerous errors, has entirely superseded it.

EUGE'NIA. (So named by Micheli, in compliment to Prince Eugene of Savoy, who sent him from Germany almost all the plants described by Clusius.) The name of a genus of plants in the Linnæan system. Class, *Icosandria;* Order, *Monogynia.*

EUGENIA CARYOPHYLLATA. The systematic name of the tree which affords the clove. *Caryophyllus aromaticus.* It grows in the East Indies, the Moluccas, &c. The clove is the unexpanded flower, or rather the calyx; it has a strong agreeable smell, and a bitterish, hot, not very pungent taste. The oil of cloves, commonly met with in the shops, and received from the Dutch, is highly acrimonious and sophisticated. Clove is accounted the hottest and most acrid of the aromatics; and, by acting as a powerful stimulant to the muscular fibres, may, in some cases of atonic gout, paralysis, &c. supersede most others of the aromatic class; and the foreign oil, by its great acrimony, is also well adapted for several external purposes; it is directed by several pharmacopœias, and the clove itself enters many officinal preparations.

EUGENIA JAMBOS. The systematic name of the Malabar plum-tree. The fruit smells, when ripe, like roses. On the coast of Malabar, where the trees grow plentifully, these plums are in great esteem. They are not only eaten fresh off the trees, but are preserved in sugar, in order to have them eatable all the year. Of the flowers, a conserve is prepared, which is used medicinally as a mild adstringent.

EUGE'US. (From ευ, well, and γη, the earth: so called because of its fertility.) The uterus.

EUKAIRITE. A new mineral composed of silver, selenium, copper, and alumina, found in the copper mine of Skrickerum, in Swisserland.

EU'LE. (From ευλαζω, to putrefy.) A worm bred in foul and putrid ulcers.

EUNU'CHIUM. (From ευνουχος, an eunuch: so called because it was formerly said to render those who eat it impotent, like an eunuch.) The lettuce. See *Lactuca.*

EUPATORIOPHA'LACRON. (From ευπατωριον, agrimony, and φαλακρος, bald.) A species of agrimony with naked heads.

EUPATO'RIUM. (From *Eupator*, its discoverer: or *quasi hepatorium*, from ηπαρ, the liver; because it was said to be useful in diseases of the liver.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Polygamia æqualis.*

2. The pharmacopœial name of the *Eupatorium.* See *Eupatorium cannabinum.*

EUPATORIUM ARABICUM. See *Eupatorium cannabinum.*

EUPATORIUM CANNABINUM. The systematic name of the hemp agrimony. *Eupatorium; Eupatorium arabicum.* The juice of this very bitter and strong-smelling plant, *Eupatorium—foliis digitatis* of Linnæus, proves violently emetic and purgative, if taken in sufficient quantity, and promotes the secretions generally. It is recommended in dropsies, jaundices, agues, &c. and is in common use in Holland among the lower orders, as a purifier of the blood in old ulcers, scurvy, and anasarca.

Eupatorium mesues. See *Achillea ageratum.*

EUPE'PSIA. (From ευ, well, and πεπτω, to concoct.) A good digestion.

EUPE'PTIC. (*Eupepticus*; from ευ, good, and πεπτω, to digest.) That which is of easy digestion.

EUPHODITE. A species of rock, composed of felspar and diallage.

EUPHO'RBIA. The name of a genus of plants in the Linnæan system. Class, *Dodecandria*; Order, *Trigynia.*

Euphorbia antiquorum. The systematic name of a plant supposed to produce the *Euphorbium.*

Euphorbia canariensis. In the Canary islands this species of spurge affords the gum euphorbium.

Euphorbia cyparissias. The systematic name of the cyprus spurge. *Esula minor; Tithymalus cyparissius.* This, like most of the spurges, is very acrimonious, inflaming the eyes and œsophagus after touching them. It is now fallen into disuse, whatever were its virtues formerly, which, no doubt, among some others, was that of opening the bowels; for, among rustics, it was called poor man's rhubarb.

Euphorbia lathyris. The systematic name of the plant which affords the lesser cataputia seeds. *Cataputia minor; Euphorbia—umbella quadrifida, dichotoma, foliis oppositis integerrimis* of Linnæus. The seeds possess purgative properties; but if exhibited in an over-dose, prove drastic and poisonous: a quality peculiar to all the *Euphorbiæ.*

Euphorbia officinarum. The systematic name of the plant which affords the euphorbium in the greatest abundance. Euphorbium is an inodorous gum-resin, in yellow tears, which have the appearance of being worm-eaten; said to be obtained from several species of euphorbiæ, but principally from the *Euphorbia officinarum; aculatea nuda multangularis, aculeis geminatis* of Linnæus: it is imported from Ethiopia, Libya, and Mauritania. It contains an active resin, and is very seldom employed internally, but as an ingredient, it enters into many resolvent and discutient plasters.

Euphorbia palustris. The systematic name of the greater spurge. The officinal plant ordered by the name, *Esula major*, in some pharmacopœias, is the *Euphorbia palustris; umbella multifida, bifida, involucellis ovatis, foliis lanceolatis, ramis sterilibus* of Linnæus. The juice is exhibited in Russia as a common purge; and the plant is given, in some places, in the cure of intermittents.

Euphorbia paralias. *Tithymalus paralios.* Sea-purge. Every part of this plant is violently cathartic and irritating, inflaming the mouth and fauces. It is seldom employed in the practice of this country; but where it is used vinegar is recommended to correct its irritating power.

EUPHO'RBIUM. (From *Euphorbus*, the physician of king Juba, in honour of whom it was named.) See *Euphorbia officinarum.*

EUPHRA'SIA. (Corrupted from *Euphrosyne*, ευφροσυνη, from ευφρων, joyful: so called because it exhilarates the spirits.)

1. The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Angiospermia.*

2. The pharmacopœial name of eye-bright. See *Euphrasia officinalis.*

Euphrasia officinalis. The systematic name of the eye-bright. This beautiful little plant, *Euphrasia—foliis ovatis, lineatis, argute dentatis* of Linnæus, has been greatly esteemed by the common people, as a remedy for all diseases of the eyes; yet, notwithstanding this, and the encomiums of some medical writers, is now wholly fallen into disuse. It is an ingredient in the British herb-tobacco.

Eustachian tube. *Tuba eustachiana.* The tube so called was discovered by the great Eustachius. It begins, one in each ear, from the anterior extremity of the tympanum, and runs forwards and inwards in a bony canal, which terminates with the petrous portion of the temporal bone. It then goes on, partly cartilaginous, and partly membranous, gradually becoming larger, and at length ends behind the soft palate. Through this tube the air passes to the tympanum.

Eustachian valve. See *Valvula Eustachii.*

EUSTACHIUS, Bartholomew, one of the most celebrated anatomists of the 16th century, was born at San Severino, in Italy. He studied at Rome, and made himself such a proficient in anatomy, that he was chosen professor of that branch of medicine there, where he died in 1574. He was author of several works, many of which are lost, especially his treatise "De Controversiis Anatomicorum," which is much regretted. He made several discoveries in anatomy; having first described the renal capsules, and the thoracic duct; also the passage from the throat to the internal ear, named after him the Eustachian tube. A series of copper-plates, to which he alludes in his "Opuscula," were recovered by Lancisi, and published in the beginning of the 18th century. He edited the Lexicon of Erotian with a commentary.

EUTHYPO'RIA. (From Ευθυς, straight, and πορος, a passage.) *Euthyporos.* An extension made in a straight line, to put in place a fracture, or dislocation.

EVAPORA'TION. A chemical operation usually performed by applying heat to any compound substance, in order to dispel the volatile parts. "It differs from distillation in its object, which chiefly consists in preserving the more fixed matters, while the volatile substances are dissipated and lost. And the vessels are accordingly different: evaporation being commonly made in open shallow vessels, and distillation in an apparatus nearly closed from the external air.

The degree of heat must be duly regulated in evaporation. When the fixed and more volatile matters do not greatly differ in their tendency to fly off, the heat must be very carefully adjusted; but in other cases this is less necessary.

As evaporation consists in the assumption of the elastic form, its rapidity will be in proportion to the degree of heat, and the diminution of the pressure of the atmosphere. A current of air is likewise of service in this process.

Barry has lately obtained a patent for an apparatus, by which vegetable extracts for the apothecary may be made at a very gentle heat, and *in vacuo.* From these two circumstances, extracts thus prepared differ from those in common use, not only in their physical, but medicinal properties. The taste and smell of the extract of hemlock made in this way are remarkably different, as is the colour both of the soluble and feculent parts. The form of apparatus is as follows:—

The evaporating-pan, or still, is a hemispherical dish of cast-iron, polished on its inner surface, and furnished with an air-tight flat lid. From the centre of this a pipe rises, and bending like the neck of a retort, it forms a declining tube, which terminates in a copper sphere of a capacity three (four?) times greater than that of the still.

There is a stop-cock on that pipe, midway between the still and the globe, and another at the under side of the latter.

The manner of setting it to work is this:—The juice, or infusion, is introduced through a large opening into the polished iron still, which is then closed, made air-tight, and covered with water. The stop-cock which leads to the sphere is also shut. In order to produce the vacuum, steam from a separate apparatus is made to rush by a pipe through the sphere, till it has expelled all the air, for which five minutes are commonly sufficient. This is known to be effected, by the steam issuing uncondensed. At that instant the copper sphere is closed, the steam shut off, and cold water admitted on its external surface. The vacuum thus produced in the copper sphere, which contains four-fifths of the air of the whole apparatus, is now partially transferred to the still, by opening the intermediate stop-cock. Thus, four-fifths of the air in the still rush into the sphere, and the stop-cock being shut again, a second exhaustion is effected by steam in the same manner as the first was; after which a momentary communication is again allowed between the iron still and the receiver; by this means, four-fifths of the air remaining after the former exhaustion, are expelled. These exhaustions, repeated five or six times, are usually found sufficient to raise the mercurial column to the height of 28 inches. The water-bath, in which the iron still is immersed, is now to be heated, until the fluid that is to be inspissated begins to boil, which is known by inspection through a window in the apparatus, made by fastening on, air-tight, a piece of very strong glass; and the temperature at which the boiling point is kept up, is determined by a thermometer. *Ebullition* is continued until the fluid is inspissated to the proper degree of consistence, which also is tolerably judged of by its appearance through the glass window. The temperature of the boiling fluid is usually about 100° F., but it might be reduced to nearly 90°.

In the Medico-chirurgical Transactions for 1819, (vol. x.) there is a paper by J. T. Barry on a new method of preparing Pharmaceutical Extracts. It consists in performing the evaporation *in vacuo*. For this purpose he employed apparatus which was found to answer so well, that, contemplating its application to other manufactures, he was induced to take out a patent for it, that is to say, *for the apparatus*. As it has been erroneously supposed that the patent is for preparing extracts *in vacuo*, it may not be improper to correct the statement by a short quotation from the above paper. 'On that account, I have been induced to take out a patent for it, (the apparatus.) It is, however, to be recollected by this society, that I have declined having a patent for its pharmaceutical products. Chemists, desirous of inspissating extracts *in vacuo*, are therefore at liberty to do it in any apparatus differing from that which has been made the subject of my patent; and thus these substances may continue the object of fair competition as to quality and price.'

The apparatus combines two striking improvements. The first consists in producing a vacuum by the agency of *steam only*, so that the use of air-pumps and the machinery requisite for working them, is superseded.

The other improvement is a contrivance for superseding the injection of water during the process of evaporation *in vacuo*."

Evergreen leaf. See *Sempervirens.*

Everriculum. (From *everro*, to sweep away.) A sort of spoon, used to clear the bladder from gravel.

EXACERBATION. (*Exacerbatio*; from *exacerbo*, to become violent.) An increase of the force or violence of the symptoms of a disease. The term is generally applied to an increase of febrile symptoms.

EXÆ'RESIS. (From εξαιρεω, to remove.) One of the divisions of surgery adopted by the old surgeons; the term implies the removal of parts.

Exa'lma. (From εξαλλομαι, to leap out.) Hippocrates applies it to the starting of the vertebræ out of their places.

EXAMBLO'MA. (From εξαμβλοω, to miscarry.) An abortion.

EXAMBLO'SIS. An abortion.

Exanastomo'sis. (From εξαναστομοω, to relax, or open.) The opening of the mouths of vessels, to discharge their contents.

EXANGIA. (*Exangia*; from *ex*, and αγγειον, a vessel.) The name of a genus, class, *Hæmatica*; order, *Dysthetica*, in Good's Nosology. It embraces three species, *Exangia aneurisma, varix, cyania.*

EXANTHE'MA. (*Exanthema, atis.* n.; from εξανθεω, *effloresco*, to effloresce, or break forth on the surface.) *Exanthisma.* An eruption of the skin, called a rash. It consists of red patches on the skin, variously figured; in general confluent, and diffused irregularly over the body, leaving interstices of a natural colour. Portions of the cuticle are often elevated in a rash, but the elevations are not acuminated. The eruption is usually accompanied with a general disorder of the constitution, and terminates in a few days by cuticular exfoliations.

EXANTHE'MATA. (The plural of *exanthema*.) The name of an order of diseases of the class *Pyrexiæ* in Cullen's Nosology. It includes diseases, beginning with fever, and followed by an eruption on the skin.

EXANTHEMATICA. The name of an order of diseases, class, *Hæmatica*, in Good's Nosology. Eruptive fevers. It comprehends four genera, viz. *Exanthesis, Emphlyis, Empyesis, Anthracia.*

EXANTHESIS. (From εξ, *extra*, and ανθεω, *floreo*.) The name of a genus of disease, class, *Eccritica*; order, *Acrotica*, in Good's Nosology. Cutaneous blush. It affords only one species, *Exanthesis roseola.*

Exanthi'sma. See *Exanthema.*

Exanthro'pia. (From εξ, without, and ανθρωπος, a man, *i. e.* having lost the faculties of a man.) A species of melancholy, in which the patient fancies himself some kind of brute.

Exara'gma. (From εξάραττω, to break.) A fracture.

Exa'rma. (From εξαιρω, to lift up.) A tumour or swelling.

Exarte'ma. (From εξαρταω, to suspend.) A charm, hung round the neck.

Exarthre'ma. (From εξαρθροω, to put out of joint.) *Exarthroma*; *Exarthrosis.* A dislocation, or luxation.

Exarthro'ma. See *Exarthrema.*

Exarthro'sis. See *Exarthrema.*

EXARTICULA'TIO. (From *ex*, out of, and *articulus*, a joint.) A luxation, or dislocation of a bone from its socket.

Exci'pulum. (From *excipio*, to receive.) A chemical receiver.

EXCITABI'LITY. That condition of living bodies wherein they can be made to exhibit the functions and phenomena which distinguish them from inanimate matter, or the capacity of organised beings to be affected by various agents called *exciting powers.*

Much confusion seems to have arisen in medical controversies from the application of the word *stimuli*, to denote the means necessary to the support of life; and particularly by Brown, in his celebrated attempt to reduce the varied and complicated states of the system to the reciprocal action of the exciting powers upon the excitability. By this hypothesis, instead of regarding life as a continued series of actions, which cannot go on without certain agents constantly ministering to them, we are to suppose a substance or quality, called *excitability*, which is superadded or assigned to every being upon the commencement of its living state. The founder of the Brunonian school considers that this substance or quality is expanded by the incessant action of the exciting powers. These are—air, food, and drink, the blood and the secretions, as well as muscular exertion, sensation, thought, and passions, or emotion, or other functions of the system itself; and these powers, which exhaust the excitability or produce *excitement* (according to the language of the school,) are strangely enough called *stimuli*. We are told, that it is in the due balance between the exciting powers and the excitability that health consists: for if the exciting powers be in excess, *indirect debility* is produced; and where, on the other hand, the stimuli are deficient and the excitability accumulated, there ensues a state of *direct debility*.

EXCITATION. (*Excitatio; from excito*, to excite.) The act of awakening, rousing, or producing some power or action: thus we say, the excitation of motion, excitation of heat, excitation of the passions, &c. In natural philosophy, it is principally used in the subjects of action of living parts, and in electricity and heat.

EXCI'TEMENT. According to the opinion of Brown, excitement is the continual exhaustion of the *matter of life*, or excitability by certain agents, which have received the name of *stimuli* or exciting powers. The due degree of this expension or excitement is the condition necessary to health: the excessive action of stimuli causing indirect debility and generating *sthenic* diseases, while the opposite state of deficient excitement produces direct debility, and gives birth to *asthenic* diseases; and death is said to result equally from complete exhaustion of the excitability, and from total absence of the exciting powers. Excitement is in this view equivalent to that *forced* state which is supposed by the Brunonian school to constitute life.

It has been objected to this hypothesis, that by simplifying too much the varied phenomena of healthy functions and of diseases, it necessarily classed together conditions of the system which have been considered as widely different, and of opposite tendencies, by the more patient observer. And though gladly caught at by many as pointing out in a few general rules the mode of cure in all diseases, namely, by restoring the proper equilibrium between excitability and the action of stimuli, the Brunonian theories seem now to be considered, by those who are suspicious of bold classifications, as an example of the observation, "that the most ingenious way of becoming foolish is by a system; and the surest way to prevent truth, is to set up something in the room of it."

EXCITING. That which has the power of impressing the solids, so as to alter their action, and thus produce disease.

Exciting cause. That which, when applied to the body, excites a disease.

EXCORIA'TION. (*Excoriatio; from excorio*, to take off the skin.) An abrasion of the skin.

E'XCREMENT. (*Excrementum; from excerno*, to separate from.) The alvine fæces.

EXCRE'SCENCE. (*Excrescentia; from excresco*, to grow from.) Any preternatural formation of flesh, or any part of the body, as wens, warts, &c.

EXCRE'TION. (*Excretio; from excerno*, to separate from.) This term is applied to the separation of those fluids from the blood of an animal, that are supposed to be useless, as the urine, perspiration, and alvine fæces. The process is the same with that of secretion, except with the alvine fæces; but the term excretion is applied to those substances which, when separated from the blood, are not applied to any useful purposes in the animal economy.

EXCRETORY. (*Excretorius; from excerno*, to purge, sift, &c.) This name is applied to certain little ducts or vessels in the fabric of glands; thus the tubes which convey the secretion out of the testicle into the vesiculæ seminales are called the excretory ducts.

EXERCISE. See *Æora*.

EXFOLIA'TION. (*Exfoliatio; from exfolio*, to cast the leaf.) The separation of a dead piece of bone from the living.

Exfoliati'vum. (From *exfolio*, to shed the leaf.) A raspatory or instrument for scraping exfoliating portions of bone.

Exi'schios. (From εξ, out of, and ισχιον, the ischium.) A luxation of the thigh-bone.

Exitu'ra. (From *exco*, to come from.) A running abscess.

E'xitus. (From *exeo*, to come out.) A prolapsus, or falling down of a part of the womb or bowel.

E'xochas. (From εξω, without, and εχω, to have.) *Exoche*. A tubercle on the outside of the anus.

E'xoche. See *Exochas*.

Exocy'ste. See *Exocystis*.

Exocy'stis. (From εξω, without, and κυστις, the bladder.) *Exocyste*. A prolapsus of the inner membrane of the bladder.

EXO'MPHALUS. (From εξ, out, and ομφαλος, the navel.) *Exomphalos*. An umbilical hernia. See *Hernia umbilicalis*.

Exoncho'ma. (From εξ, and ογχος, a tumour.) A large prominent tumour.

EXOPHTHA'LMIA. (From εξ, out, and οφθαλμος, the eye.) A swelling or protusion of the bulb of the eye, to such a degree that the eye-lids cannot cover it. It may be caused by inflammation, when it is termed *exophthalmia inflammatoria*; or from a collection of pus in the globe of the eye, when it is termed the *exophthalmia purulenta*; or from a congestion of blood within the globe of the eye, *exophthalmia sanguinea*.

EXORMIA. (Εξορμια; from εξορμαω, to break out.) The name of a genus of disease, class, *Eccritica*; order, *Acrotica*, in Good's Nosology. Papulous skin. It has four species, viz. *Exormia strophalus, lichen, prurigo, milium*.

EXOSTO'SIS. (From εξ, and οστεον, a bone.) *Hyperostosis*. A morbid enlargement, or hard tumour of a bone. A genus of disease arranged by Cullen in the class *Locales*, and order *Tumores*. The bones most frequently affected with extososis, are those of the cranium, the lower jaw, sternum, humerus, radius, ulna, bones of the carpus, the femur, and tibia. There is, however, no bone of the body, which may not become the seat of this disease. It is not uncommon to find the bones of the cranium affected with exostosis, in their whole extent. The ossa parietalia sometimes become an inch thick.

The exostosis, however, mostly rises from the surface of the bone, in the form of a hard round tumour: and venereal exostoses, or nodes, are observed to arise chiefly on compact bones, and such of these as are only superficially covered with soft parts; as, for instance, the bones of the cranium, and the front surface of the tibia.

EXPANSION. The increase of surface, or of bulk, to which natural bodies are susceptible.

EXPE'CTORANT. (*Expectorans;* from *expectoro,* to discharge from the breast.) Those medicines which increase the discharge of mucus from the lungs. The different articles referred to this class may be divided into the following orders:

1. *Nauseating expectorants;* as squill, ammoniacum, and garlic, which are to be preferred for the aged and phlegmatic.

2. *Stimulating expectorants;* as marrubium, which is adapted to the young and irritable, and those easily affected by expectorants.

3. *Antispasmodic expectorants;* as vesicatories, pediluvium, and watery vapours: these are best calculated for the plethoric and irritable, and those liable to spasmodic affections.

4. *Irritating expectorants;* as fumes of tobacco and acid vapours. The constitutions to which these are chiefly adapted, are those past the period of youth, and those in whom there are evident marks of torpor, either in the system generally, or in the lungs in particular.

EXPERIENCE. A kind of knowledge acquired by long use without any teacher. Experience consists in the ideas of things we have seen or read, which the judgment has reflected on, to form for itself a rule or method.

EXPERS. Wanting; destitute. The trivial name of some diseases; as dipsosis expers, in which the thirst is wanting.

EXPIRA'TION. (*Expiratio;* from *expiro,* to breathe.) That part of respiration in which the air is thrust out from the lungs. See *Respiration.*

Expressed oil. Such oils as are obtained by pressing the substance containing them; as olives, which give out olive oil, almonds, &c.

EXSUCCA'TIO. (From *ex,* out of, and *succus,* humour.) An ecchymosis, or extravasation of humours, under the integuments.

EXTE'NSOR. (From *extendo,* to stretch out.) A term given to those muscles the office of which it is to extend any part; the term is in opposition to flexor.

EXTENSOR BREVIS DIGITORUM PEDIS. A muscle of the toes situated on the foot. *Extensor brevis* of Douglas. *Calcano phalanginien commune* of Dumas. It arises fleshy and tendinous from the fore and upper part of the os calcis, and soon forms a fleshy belly, divisible into four portions, which send off an equal number of tendons that pass over the upper part of the foot, under the tendons of the extensor longus digitorum pedis, to be inserted into its tendinous expansion. Its office is to extend the toes.

EXTENSOR CARPI RADIALIS BREVIOR. An extensor muscle of the wrist, situated on the fore-arm. *Radialis externus brevior* of Albinus. *Radialis secundus* of Winslow. It arises tendinous from the external condyle of the humerus, and from the ligament that connects the radius to it, and runs along the outside of the radius. It is inserted by a long tendon into the upper and back part of the metacarpal bone of the middle finger. It assists in extending and bringing the hand backward.

EXTENSOR CARPI RADIALIS LONGIOR. An extensor muscle of the carpus, situated on the fore-arm, that acts in conjunction with the former. *Radialis externus longior* of Albinus. *Radialis externus primus* of Winslow. It arises thin, broad, and fleshy, from the lower part of the external ridge of the os humeri, above its external condyle, and is inserted by a round tendon into the posterior and upper part of the metacarpal bone that sustains the fore-fingers.

EXTENSOR CARPI ULNARIS. *Ulnaris externus* of Albinus and Winslow. It arises from the outer condyle of the os humeri, and then receives an origin from the edge of the ulna; its tendon passes in a groove behind the styloid process of the ulna, to be inserted into the inside of the basis of the metacarpal bone of the little finger.

EXTENSOR DIGITORUM COMMUNIS. A muscle situated on the fore-arm, that extends all the joints of the fingers. *Extensor digitorum communis manus* of Douglas and Winslow. *Extensor digitorum communis, seu digitorum tensor* of Cowper, and *Epichondylo-suspha-langettien commune* of Dumas. *Cum extensore proprio auricularis* of Albinus. It arises from the external protuberance of the humerus: and at the wrist it divides into three flat tendons, which pass under the annular ligament, to be inserted into all the bones of the fore, middle, and ring fingers.

EXTENSOR DIGITORUM LONGUS. See *Extensor longus digitorum pedis.*

EXTENSOR INDICIS. See *Indicator.*

EXTENSOR LONGUS DIGITORUM PEDIS. A muscle situated on the leg, that extends all the joints of the four small toes. *Extensor digitorum longus. Peroneo-tibisus-phalangittien commune* of Dumas. It arises from the upper part of the tibia and fibula, and the interosseous ligament; its tendon passes under the annular ligament, and then divides into five, four of which are inserted into the second and third phalanges of the toes, and the fifth goes to the basis of the metatarsal bone. This last, Winslow reckons a distinct muscle, and calls it *Peroneus brevis.*

EXTENSOR LONGUS POLLICIS PEDIS. See *Extensor proprius pollicis pedis.*

EXTENSOR MAGNUS. See *Gastrocnemius internus.*

EXTENSOR MAJOR POLLICIS MANUS. See *Extensor secundi internodii.*

EXTENSOR MINOR POLLICIS MANUS. See *Extensor primi internodii.*

EXTENSOR OSSIS METACARPI POLLICIS MANUS. An extensor muscle of the wrist situated on the fore-arm. *Abductor longus pollicis manus* of Albinus. *Extensor primi internodii* of Douglas. *Extensor primus pollicis* of Winslow. *Extensor primi internodii pollicis* of Cowper. *Cubito-radisus metacarpien du pouce* of Dumas. It arises fleshy from the middle and posterior part of the ulna, from the posterior part of the middle of the radius, and from the interosseous ligament, and is inserted into the os trapezium, and upper part of the metacarpal bone of the thumb.

EXTENSOR POLLICIS PRIMUS. See *Extensor primi internodii.*

EXTENSOR POLLICIS SECUNDUS. See *Extensor secundi internodii.*

EXTENSOR PRIMI INTERNODII. A muscle of the thumb situated on the hand, that extends the first bone of the thumb obliquely outwards. *Extensor minor pollicis manus* of Albinus. This muscle, and the *Extensor ossis metacarpi pollicis manus,* are called *Extensor pollicis primus* by Winslow; *Extensor secundi internodii* by Douglas; *Extensor secundi internodii ossis pollicis* of Cowper. *Cubito-susphalangien du pouce* of Dumas. It arises fleshy from the posterior part of the ulna, and from the interosseous ligament, and is inserted tendinous into the posterior part of the first bone of the thumb.

EXTENSOR PROPRIUS POLLICIS PEDIS. An

exterior muscle of the great toe, situated on the foot. *Extensor longus* of Douglas. *Extensor pollicis longus* of Winslow and Cowper. *Peroneo susphalangien du pouce* of Dumas. It arises by an acute, tendinous, and fleshy beginning, some way below the head, and anterior part of the fibula, along which it runs to near its lower extremity, connected to it by a number of fleshy fibres, which descend obliquely, and form a tendon, which is inserted into the posterior part of the first and last joint of the great toe.

EXTENSOR SECUNDI INTERNODII. A muscle of the thumb, situated on the hand, that extends the last joint of the thumb obliquely backwards. *Extensor major pollicis manus* of Albinus. *Extensor pollicis secundus* of Winslow. *Extensor tertii internodii* of Douglas. *Extensor internodii ossis pollicis* of Cowper. *Cubito susphalangettien du pouce* of Dumas. It arises tendinous and fleshy from the middle part of the ulna, and interosseous ligament; it then forms a tendon, which runs through a small groove at the inner and back part of the radius, to be inserted into the last bone of the thumb. Its use is to extend the last phalanx of the thumb obliquely backwards.

EXTENSOR SECUNDI INTERNODII INDICIS PROPRIUS. See *Indicator.*

EXTENSOR TARSI MINOR. See *Plantaris.*

EXTENSOR TARSI SURALIS. See *Gastrocnemius internus.*

EXTENSOR TERTII INTERNODII INDICIS. See *Prior indicis.*

EXTENSOR TERTII INTERNODII MINIMI DIGITI. See *Abductor minimi digiti manus.*

EXTERNUS MALLEI. See *Laxator tympani.*

EXTIPULATUS. Without stipulæ. A botanical term. Applied to stems.

EXTIRPA'TION. (*Extirpatio*; from *extirpo*, to eradicate.) The complete removal or destruction of any part, either by cutting instruments, or the action of caustics.

E'XTRACT. *Extractum.* 1. When chemists use this term, they generally mean the product of an aqueous decoction.

2. In pharmacy it includes all those preparations from vegetables which are separated by the agency of various liquids, and afterwards obtained from such solutions, in a solid state, by evaporation of the menstruum. It also includes those substances which are held in solution by the natural juices of fresh plants, as well as those to which some menstruum is added at the time of preparation. Now, such soluble matters are various, and mostly complicated; so that chemical accuracy is not to be looked for in the application of the term. Some chemists, however, have affixed this name to one peculiar modification of vegetable matter, which has been called *extractive*, or extract, or extractive principle; and, as this forms one constituent part of common extracts, and possesses certain characters, it will be proper to mention such of them as may influence its pharmaceutical relations. The extractive principle has a strong taste, differing in different plants: it is soluble in water, and its solution speedily runs into a state of putrefaction, by which it is destroyed. Repeated evaporations and solutions render it at last insoluble, in consequence of its combination with oxygen from the atmosphere. It is soluble in alkohol, but insoluble in æther. It unites with alumine, and if boiled with neutral salts thereof, precipitates them. It precipitates with strong acids, and with the oxides from solutions of most metallic salts, especially muriate of tin. It readily unites with alkalies, and forms compounds with them, which are soluble in water. No part, however, of this subject, has been hitherto sufficiently examined.

In the preparation of all the extracts, the London Pharmacopœia requires that the water be evaporated as speedily as possible, in a broad, shallow dish, by means of a water-bath, until they have acquired a consistence proper for making pills; and, towards the end of the inspissation, that they should be constantly stirred with a wooden rod. These general rules require minute and accurate attention, more particularly in the immediate evaporation of the solution, whether prepared by expression or decoction, in the manner as well as the degree of heat by which it is performed, and the promotion of it by changing the surface by constant stirring, when the liquor begins to thicken, and even by directing a strong current of air over its surface, if it can conveniently be done. It is impossible to regulate the temperature over a naked fire, or, if it be used, to prevent the extract from burning; the use of a water bath is, therefore, absolutely necessary, and not to be dispensed with, and the beauty and precision of extracts so prepared, will demonstrate their superiority.

EXTRAC'TION. (*Extractio*; from *extraho*, to draw out.) The taking extraneous substances out of the body. Thus bullets and splinters are said to be *extracted* from wounds; stones from the urethra, or bladder. Surgeons also sometimes apply the term *extraction* to the removal of tumours out of cavities, as for instance, to the taking of cartilaginous tumours out of the joints. They seldom speak of extracting any diseased original part of the body; though they do so in one example, viz. the cataract.

EXTRA'CTIVE. See *Extract.*

EXTRA'CTUM. (From *extraho*, to draw out.) An extract. See *Extract.*

EXTRACTUM ACONITI. Extract of aconite. Take of aconite leaves, fresh, a pound; bruise them in a stone mortar, sprinkling on a little water; then press out the juice, and, without any separation of the sediment, evaporate it to a proper consistence. The dose is from one grain to five grains. For its virtues, see *Aconitum.*

EXTRACTUM ALOES PURIFICATUM. Purified extract of aloes. Take of extract of spike aloe, powdered, half a pound; boiling water, four pints. Macerate for three days in a gentle heat, then strain the solution, and set it by, that the dregs may subside. Pour off the clear solution, and evaporate it to a proper consistence. The dose, from five to fifteen grains. See *Aloës.*

EXTRACTUM ANTHEMIDIS. Extract of chamomile, formerly called extractum chamæmeli. Take of chamomile flowers, dried, a pound; water, a gallon; boil down to four pints, and strain the solution while it is hot, then evaporate it to a proper consistence. The dose is ten grains to a scruple. For its virtues, see *Anthemis nobilis.*

EXTRACTUM BELLADONNÆ. Extract of belladonna. Take of deadly night shade leaves, fresh, a pound. Bruise them in a stone mortar, sprinkling on a little water; then press out the juice, and without any previous separation of the sediment, evaporate it to a proper consistence. The dose is from one to five grains. For its virtues, see *Atropa belladonna.*

EXTRACTUM CINCHONÆ. Extract of bark. Take of lance-leaved cinchona bark, bruised, a pound; water a gallon; boil down to six pints, and strain the liquor, while hot. In the same manner, with an equal quantity of water, four times boil down, and strain. Lastly consume all the liquors, mixed together, to a proper consistence. This extract should be kept soft, for making pills, and hard to be reduced to powder.

EXTRACTUM CINCHONÆ RESINOSUM. Resinous extract of bark. Take of lance-leaved cinchona bark, bruised, a pound; rectified spirit, four pints; macerate for four days and strain. Distil the tincture in the heat of a water-bath, until the extract has acquired a proper consistence. This is considered by many as much more grateful to the stomach, and, at the same time, producing all the effects of bark in substance, and by the distillation of it, it is intended that the spirit which passes over shall be collected and preserved. The dose is from ten grains to half a drachm. See *Cinchona*.

EXTRACTUM COLOCYNTHIDIS. Extract of colocynth. Take of colocynth pulp, a pound; water, a gallon; boil down to four pints, and strain the solution while it is hot, and evaporate it to a proper consistence. The dose is from five to thirty grains. For its virtues, see *Cucumis colocynthis*.

EXTRACTUM COLOCYNTHIDIS COMPOSITUM. Compound extract of colocynth. Take of colocynth pulp, sliced, six drachms; extract of spike aloe, powdered, an ounce and half; scammony gum-resin, powdered, half an ounce; cardamom seeds, powdered, a drachm; proof spirit, a pint. Macerate the colocynth pulp in the spirit, for four days, in a gentle heat: strain the solution, and add it to the aloes and scammony; then, by means of a water bath, evaporate it to a proper consistence, constantly stirring, and about the end of the inspissation, mix in the cardamom-seeds. The dose from five to thirty grains.

EXTRACTUM CONII. Extract of hemlock, formerly called succus cicutæ spissatus. Take of fresh hemlock, a pound. Bruise it in a stone mortar, sprinkling on a little water; then press out the juice, and, without any separation to the sediment, evaporate it to a proper consistence. The dose from five grains to a scruple.

EXTRACTUM ELATERII. Extract of elaterium. Cut the ripe, wild cucumbers into slices, and pass the juice, very gently expressed, through a very fine hair sieve, into a glass vessel; then set it by for some hours, until the thicker part has subsided. Pour off, and throw away the thinner part, which swims at the top. Dry the thicker part which remains in a gentle heat. The dose, from half a grain to three grains. For its virtues, see *Momordica elaterium*.

EXTRACTUM GENTIANÆ. Extract of gentian. Take of gentian root, sliced, a pound; boiling water, a gallon; macerate for twenty-four hours, then boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence. Dose from ten to thirty grains. See *Gentiana*.

EXTRACTUM GLYCYRRHIZÆ. Extract of liquorice. Take of liquorice root, sliced, a pound; boiling water, a gallon; macerate for twenty-four hours, then boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence. Dose, from one drachm to half an ounce. See *Glycyrrhiza*.

EXTRACTUM HÆMATOXYLI. Extract of logwood, formerly called extractum ligni campechensis. Take of logwood, powdered, a pound; boiling water, a gallon; macerate for twenty-four hours; then boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence. Dose from ten grains to half a drachm. For its virtues, see *Hæmatoxylon campechianum*.

EXTRACTUM HUMULI. Extract of hops. Take of hops, four ounces; boiling water, a gallon; boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence. This extract is said to produce a tonic and sedative power combined; the dose is from five grains to one scruple. See *Humulus lupulus*.

EXTRACTUM HYOSCYAMI. Extract of henbane. Take of fresh henbane leaves, a pound; bruise them in a stone mortar, sprinkling on a little water; then press out the juice, and, without separating the fæculencies, evaporate it to a proper consistence. Dose from five to thirty grains. For its virtues, see *Hyoscyamus*.

EXTRACTUM JALAPÆ. Extract of jalap. Take of jalap-root powdered, a pound; rectified spirit, four pints; water, ten pints; macerate the jalap-root in the spirits for four days, and pour off the tincture; boil the remaining powder in the water, until it be reduced to two pints; then strain the tincture and decoction separately, and let the former be distilled and the latter evaporated, until each begins to grow thick. Lastly, mix the extract with the resin, and reduce it to a proper consistence. Let this extract be kept in a soft state, fit for forming pills, and in a hard one, so that it may be reduced to powder. The dose from ten to twenty grains. For its virtues, see *Convolvulus jalapa*.

EXTRACTUM OPII. Extract of opium, formerly called extractum thebaicum. Opium colatum. Take of opium, sliced, half a pound; water, three pints; pour a small quantity of the water upon the opium, and macerate it for twelve hours, that it may become soft; then, adding the remaining water gradually, rub them together until the mixture be complete. Set it by, that the fæculencies may subside; then strain the liquor, and evaporate it to a proper consistence. Dose, from half a grain to five grains.

EXTRACTUM PAPAVERIS. Extract of white poppy. Take of white poppy capsules bruised, and freed from the seeds, a pound; boiling water a gallon. Macerate for twenty-four hours, then boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence. Six grains are about equivalent to one of opium. For its virtues, see *Papaver album*.

EXTRACTUM RHEI. Extract of rhubarb. Take of rhubard root, powdered, a pound; proof spirit, a pint; water, seven pints. Macerate for four days in a gentle heat, then strain and set it by, that the fæculencies may subside. Pour off the clear liquor, and evaporate to a proper consistence. This extract possesses the purgative properties of the root, and the fibrous and earthy parts are separated; it is therefore a useful basis for pills, as well as given separately. Dose, from ten to thirty grains. See *Rheum*.

EXTRACTUM SARSAPARILLÆ. Extract of sarsaparilla. Take of sarsaparilla root, sliced, a pound; boiling water, a gallon; macerate for twenty-four hours, then boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence. In practice this is much used, to render the common decoction of the same root stronger and more efficacious. Dose from ten grains to a drachm. For its virtues, see *Smilax sarsaparilla*.

EXTRACTUM SATURNI. See *Plumbi acetatis liquor*.

EXTRACTUM TARAXACI. Take of dandelion root, fresh and bruised, a pound: boiling water, a gallon: macerate for twenty-four hours; boil down to four pints, and strain the hot liquor; then evaporate it to a proper consistence. Dose, from ten grains to a drachm. For its virtues, see *Leontodon taraxacum*.

EXTRAFOLIACEUS. Applied to stipulæ, which are below the footstalk, and external with respect to the leaf; as in *Astragalus onobrichis.*

EXTRAVASA'TION. (*Extravasatio*; from *extra*, without, and *vas*, a vessel.) A term applied by surgeons to fluids, which are out of their proper vessels, or receptacles. Thus, when blood is effused on the surface, or in the ventricles of the brain, it is said that there is an extravasion. When blood is poured from the vessels into the cavity of the peritonæum, in wounds of the abdomen, surgeons call this accident *extravasation.* The urine is also said to be *extravasated*, when, in consequence of a wound, or of sloughing, or ulceration, it makes its way into the cellular substance or among the abdominal viscera. When the bile spreads among the convolutions of the bowels, in wounds of the gall-bladder, it is also a species of extravasation.

EXTREMITIES. This term is applied to the limbs, as distinguishing them from the other divisions of the animal, the head and trunk. The extremities are four in number, divided in man into upper and lower; in other animals into anterior and posterior. Each extremity is divided into four parts; the upper into the shoulder, the arm, the fore-arm, and the hand: the lower into the hip, the thigh, the leg, and the foot.

EYE. *Oculus.* The parts which constitute the eye are divided into external and internal. The external parts are:

1. The *eyebrows*, or *supercilia*, which form arches of hair above the orbit, at the lower part of the forehead. Their use is to prevent the sweat falling into the eyes, and for moderating the light above.

2. The eyelashes, or *cilia*, are the short hairs that grow on the margin of the eyelids; they keep external bodies out of the eyes and moderate the influx of light.

3. The eyelids, or *palpebræ*, of which, one is superior or upper, and the other inferior, or under; where they join outwardly, it is called the *external canthus*; inwardly, towards the nose, the *internal canthus*; they cover and defend the eyes.

The margin of the eyelids, which is cartilaginous, is called *tarsus.*

In the *tarsus*, and internal surface of the eyelids, small glands are situated, called *glandulæ Meibomianæ*, because Meibomius discovered them; they secrete an oily or mucilaginous fluid, which prevents the attrition of the eyes and eyelids, and facilitates their motions.

4. The lachrymal glands, or *glandulæ lachrymales*, which are placed near the external canthus, or corner of the eyes, in a little depression of the os frontis.

From these glands six or more canals issue, which are called lachrymal ducts, or *ductus lachrymales*, and they open on the internal surface of the upper eyelid.

5. The lachrymal caruncle, or *caruncula lachrymalis*, which is situated in the internal angle, or canthus of the eyelids.

6. *Puncta lachrymalia*, are two callous orifices or openings, which appear at the internal angle of the tarsus of the eyelids; the one in the superior, the other in the inferior eyelid.

7. The *canales lachrymales*, or lachrymal ducts, are two small canals, which proceed from the lachrymal points into the lachrymal sac.

8. The *saccus lachrymalis*, or lachrymal sac, is a membranous sac, which is situated in the internal canthus of the eye.

9. The *ductus nasalis*, or nasal duct, is a membraneous canal, which goes from the inferior part of the lachrymal sac through the bony canal below, and a little behind, into the cavity of the nose, and opens under the inferior spongy bone into the nostril.

10. The *membrana conjunctiva*, or conjunctive membrane, which, from its white colour is called also *albuginea*, or white of the eye, is a membrane which lines the internal superficies of the eyelids, and covers the whole fore-part of the globe of the eye: it is very vascular, as may be seen in inflammations.

The bulb, or globe of the eye, is composed of eight membranes, or coverings, two chambers, or *cameræ*, and three humours, improperly so called.

The membranes of the globe of the eye, are, *four* in the hinder or posterior part of the bulb, or globe, viz. *sclerotica, choroidea, retina,* and *hyaloidea*, or *arachnoidea*; *four* in the fore or anterior part of the bulb, viz. *cornea transparens, iris, uvea,* and *capsule of the crystalline lens.*

The *membrana sclerotica*, or the sclerotic or horny membrane, is the outermost. It begins from the optic nerve, forms the spherical or globular cavity, and terminates in the circular margin of the transparent cornea.

The *membrana choroidea*, or *choroides*, is the middle tonic of the bulb, of a black colour, beginning from the optic nerve, and covering the internal superficies of the sclerotica, to the margin of the transparent cornea. In this place it secedes from the cornea, and deflects transversely and inwardly, and in the middle forms a round foramen. This circular continuation of the choroidea in the anterior surface is called *iris*, in the posterior superficies, *uvea.*

The round opening in the centre is called the *pupil*, or *pupilla.* This foramen, or round opening, can be dilated, or contracted by the moving powers of almost invisible muscular fibres.

The *membrana retina*, is the innermost tunic of a white colour, and similar to mucus, being an expansion of the optic nerve, chiefly composed of its medullary part. It covers the inward surface of the choroides, to the margin of the crystalline lens, and there terminates.

The *chambers* or *cameræ* of the eyes are:

1. *Camera anterior*, or fore-chamber; an open space, which is formed anteriorly, by the hollow surface of the *cornea transparens*, and posteriorly, by the surface of the *iris.*

2. *Camera posterior*, that small space which is bounded anteriorly by the *tunica uvea*, and *pupilla*, or pupil; posteriorly by the anterior surface of the crystalline lens.

Both these chambers are filled with an aqueous humour. The humours of the eye, as they are called, are in number three:

1. The *aqueous humour*, which fills both chambers.

2. The *crystalline lens*, or humour, is a pellucid body, about the size of a lentil, which is included in an exceedingly fine membrane, or *capsula*, and lodged in a concave depression of the vitreous humour.

3. The *vitreous humour* is a pellucid, beautifully transparent substance, which fills the whole bulb of the eye behind the crystalline lens. Its external surface is surrounded with a most pellucid membrane, which is called *membrana hyaloidea*, or *arachnoidea.* In the anterior part is a fovea, or bed, for the crystalline lens.

The connection of the bulb is made anteriorly, by means of the conjunctive membrane, with the inner surface of the eyelids, or *palpebræ*; posteriorly, by the adhesion of six muscles of the bulb and the optic nerve, with the orbit.

The optic nerve, or *nervus opticus*, perforates the sclerotica and choroides, and then constitutes the retina, by spreading itself on the whole posterior part of the internal globe of the eye.

The muscles by which the eye is moved in the orbit, are six; much fat surrounds them, and fills up the cavities in which the eyes are seated. The arteries are the internal orbital, the central, and the ciliary arteries. The veins empty themselves into the external jugulars. The nerves are the optic, and branches from the third, fourth, fifth, and sixth pair.

The use of the eye is to form the organ of vision. See *Vision.*

Externally, the globe of the eye and the transparent cornea, are moistened with a most limpid fluid, called *lachrymæ*, or tears; the same pellucid subtile fluid exactly fills all the pores of the transparent cornea; for, deprived of this fluid, and being exposed to the air, that coat of the eye becomes dry, shrivelled, and cloudy, impeding the rays of light.

EYE-BRIGHT. See *Euphrasia.*

EYE-BROW. *Supercilium.* See *Eye.*

EYE-LID. *Palpebra.* See *Eye.*

Eye-tooth. The fangs of the two upper cuspidati are very much larger than those on each side and extend up near to the orbit, on which account they have been called eye-teeth. See *Teeth.*

F.

F. or ft. In a prescription these letters are abbreviations of *fiat*, or *fiant*, let it, or them be made; thus *f. bolus*, let the substance or substances prescribed be made into a bolus.

FA'BA. A bean. See *Bean.*

FABA CRASSA. See *Sedum telephium.*

FABA ÆGYPTIACA. See *Nymphæa nelumbo.*

FABA FEBRIFUGA. See *Ignatia amara.*

FABA INDICA. See *Ignatia amara.*

FABA MAJOR. The garden bean. See *Bean.*

FABA MINOR. The horse-bean. It differs no otherwise from the garden bean than in being less.

FABA PECHURIM. *Faba pichurim; Faba pechuris.* Brasilian bean. An oblong oval, brown, and ponderous seed, supposed to be the produce of a *Laurus*, brought from the Brazils. Their smell is like that of musk, between it and the scent of sassafras. They are exhibited as carminatives in flatulent colics, diarrhœas, and dysenteries.

FABA PURGATRIX. See *Ricinus.*

FABA SANCTI IGNATII. See *Ignatia amara.*

FABA SUILLA. See *Hyoscyamus.*

FABA'RIA. (From *faba*, a bean, which it resembles.) See *Sedum telephium.*

FABRICIUS, HIERONYMUS, born at *Aquapendente* in Italy, 1537. He studied at Padua under Fallopius, whom he succeeded as professor of anatomy and surgery there; which office he held for nearly half a century with great credit, and died at the advanced age of eighty-two, universally regretted. The republic of Venice also conferred many honours upon him. He is thought to have been the first to notice the valves of the veins, which he demonstrated in 1574. But his surgical works obtained him most reputation; indeed he has been called the Father of modern surgery. His first publication in 1592 contained five Dissertations on Tumours, Wounds, Ulcers, Fractures, and Dislocations. He afterwards added another part, treating of all the diseases which are curable by manual operation. This work passed through seventeen editions in different languages.

FABRICIUS, JAMES, was born at Rostock, in 1577. After travelling through different parts of Europe, he graduated at Jena, and soon gained extensive practice. He was professor of medicine and the mathematics at Rostock during forty years, and first physician to the Duke of Mecklenburgh; afterwards went to Copenhagen, and was made physician to the kings of Norway and Denmark, and died there, in 1652. He has left several tracts on medical subjects.

FABRICIUS, PHILIP CONRAD, professor of medicine at Helmstadt, was author of several useful works in anatomy and surgery. His first treatise, "Idea Anatomes Practicæ," 1741, contained some new directions in the Art of Injection, and described several branches of the Portio Dura, &c. In another work he has some good observations on the Abuse of Trepanning.

FABRICIUS, WILLIAM, better known by the name of *Hildanus*, from Hilden, in Switzerland, where he was born in 1560. He repaired to Lausanne, to complete his knowledge of surgery, at the age of twenty-six; and distinguished himself there by his assiduity, and the successful treatment of many difficult cases. He studied medicine also, and went to practise both arts at Payenne, in 1605; but ten years after was invited to Berne by the senate, who granted him a pension. In the latter part of his life, severe illness prevented his professional exertions, which had procured him general esteem, and high reputation. His death occurred in 1634. His works were written in German, but have been mostly translated into Latin. He published five "Centuries of Observations," which present many curious facts, as also several instruments invented by him.

FACE. *Facies.* The lower and anterior part of the cranium, or skull.

FA'CIAL. *Facialis.* Belonging to the face; as facial nerve, &c.

FACIAL NERVE. *Nervus facialis. Portio dura* of the auditory nerve. These nerves are two in number, and are properly the eighth pair: but are commonly called the seventh, being reckoned with the auditory, which is the portio mollis of the seventh pair. They arise from the fourth ventricle of the brain, pass through the petrous portion of the temporal bone to the face, where they form the pes anserinus, which supplies the integuments of the face and forehead.

FA'CIES. The face. See *Face.*

FACIES HIPPOCRATICA. That particular disposition of the features which immediately precedes the stroke of death is so called, because it has been so admirably described by Hippocrates.

FACIES RUBRA. See *Gutta rosacea.*

FACTI'TIOUS. A term applied to any thing which is made by art, in opposition to that which is native, or found already made in nature.

FA'CULTY. *Facultas.* The power or ability by which any action is performed.

Fæ'ces. The plural of *fæx*. The alvine excretions.

FÆ'CULA. (Diminutive of *fæx*.) A substance obtained by bruising or grinding certain vegetables in water. It is that part which, after a little, falls to the bottom. The fæcula of plants differs principally from gum or mucus in being insoluble in cold water, in which it falls with wonderful quickness. There are few plants which do not contain fæcula; but the seeds of gramineous and leguminous vegetables, and all tuberose roots contain it most plentifully.

FÆX. (*Fæx æcis*. f. an excretion.) The alvine excretions are called *fæces*.

FAGA'RA. (From *fagus*, the beech, which it resembles.) The name of a genus of plants in the Linnæan system. Class, *Tetrandria*; Order *Monogynia*.

Fagara major. See *Fagara plerota*.

Fagara octandra. The systematic name of the plant which affords *Tacamahaca*, which is a resinous substance that exudes both spontaneously, and when incisions are made into the stem of this tree; *Fagara foliolis tomentosis*, of Linnæus, and not, as was formerly supposed, from the *Populus balsamifera*. Two kinds of a tacamahaca are met with in the shops. The best, called, from its being collected in a kind of gourd shell, tacamahaca in shells, is somewhat unctuous and soft, of a pale yellowish or greenish colour, a bitterish aromatic taste, and a fragrant delightful smell, approaching to that of lavender and ambergris. The more common sort is in semitransparent grains, of a whitish, yellowish, brownish, or greenish colour, and of a less grateful smell than the former. Tacamahaca was formerly in high estimation as an ingredient in warm stimulating plasters; and although seldom used internally, it may be given with advantage as a corroborant and astringent balsamic.

Fagara plerota. *Fagara major; Castana Luzonis; Cubebis*. This plant is found in the Philippine islands. The berries are aromatic, and, according to Avicenna, heating, drying, good for cold, weak stomachs, and astringent to the bowels.

FAGOPY'RUM. (From φαγος, the beech, and πυρος, wheat; because its seeds were supposed to resemble the mast, *i. e.* fruit of beech.) See *Polygonum fagopyrum*.

Fagotri'ticum. See *Polygonum fagopyrum*.

FA'GUS. (From φαγω, to eat; its nut being one of the first fruits used by man.)

1. The name of a genus of plants in the Linnæan system. Class, *Monœcia*; Order, *Polyandria*.

2. The pharmacopœial name of the beech. See *Fagus sylvatica*.

Fagus castanea. The systematic name of the chesnut-tree. *Castanea; Lopima; Mota; Glans Jovis Theophrasti*. Jupiter's acorn; Sardinian acorn; the common chesnut. The fruit of this plant, *Fagus—foliis lanceolatis, acuminato-serratis, subtus nudis*, of Linnæus, are much esteemed as an article of luxury after dinner. Toasting renders them more easy of digestion; but notwithstanding, they must be considered as improper for weak stomachs. They are moderately nourishing, as containing sugar, and much farinaceous substance.

Fagus sylvatica. The systematic name of the beech-tree. *Fagus; Oxya; Balanda; Valanida*. The fruit and interior bark of this tree, *Fagus—foliis ovatis, obsolete serratis*, of Linnæus, are occasionally used medicinally, the former in obstinate headache, and the latter in the cure of hectic fever. The oil expressed from beech-nuts is supposed to destroy worms; a child may take two drachms of it night and morning; an adult an ounce. The poor people of Silesia use this oil instead of butter.

FAHLUMITE. A sub-species of octohedral corundum.

FAINTING. See *Syncope*.

FAIRBURN. The name of a village in the county of Ross, in the north of Britain, where there is a sulphureous spring.

FA'LCIFORM. (*Falciformis*; from *falx*, a scythe, and *forma*, resemblance.) Resembling a scythe.

Falciform process. The falx. A process of the dura mater, that arises from the crista galli, separates the hemispheres of the brain, and terminates in the tentorium.

Falde'lla. Lint, used as a compress.

Falling-sickness. See *Epilepsia*.

Fallopian tube. See *Tuba Fallopiana*.

Fallopian ligament. See *Poupart's ligament*.

FALLOPIUS, Gabriel, a physician of Modena, was born about the year 1523. He showed early great zeal in anatomy, botany, chemistry, and other branches of knowledge; and after studying in Italy, travelled to other countries for his improvement. In 1548, he was appointed professor of anatomy at Pisa, and three years after at Padua; where he also taught botany, but with less celebrity. His death happened in 1563. He distinguished himself, not only as an anatomist, but also in medicine and surgery. Douglas has characterised him as highly systematic in teaching, successful in treating diseases, and expeditious in operating. Some of the discoveries, to which he laid claim, appear to have been anticipated; as, for instance, the tubes proceeding from the uterus, though generally called after him *Fallopian*. However, he has the merit of recovering many of the observations of the ancients, which had fallen into oblivion. His "Observationes Anatomicæ," published in 1561, was one of the best works of the 16th century; in this some of the errors, which had escaped his master, Vesalius, are modestly pointed out. Many other publications, ascribed to him, were printed after his death; some of which are evidently spurious.

FALX. See *Falciform process*.

FA'MES. Hunger.

Fames canina. See *Bulimia*.

Famigerati'ssimum emplastrum. (From *famigeratus*, renowned; from *fama*, fame, and *gero*, to bear: so named from its excellence.) A plaster used in intermittent fevers, made of aromatic, irritating substances, and applied to the wrists.

FAMILY. *Familia*. A term used by naturalists to express a certain order of natural productions, agreeing in the principal characters, and containing numerous individuals, not only distinct from one another, but in whole sets, several members being to be collected out of the same family, all of which have the family character, and all some subordinate distinction peculiar to that whole number, or, though found in every individual of it, not found in those of any others.

It has been too common to confound the words, class, family, order, &c. in natural history; but the determinate meaning of the word family seems to be that larger order of creatures under which classes and orders are subordinate distinctions.

FA'RFARA. (From *farfarus*, the white poplar: so called because its leaves resemble those of the white poplar.) See *Tussilago farfaro*.

FARI'NA. (From *far*, corn, of which it is made.) Meal, or flour. A term given to the pulverulent and glutinous part of wheat, and other seeds, which is obtained by grinding and sifting. It is highly nutritious, and consists of gluten, starch, and mucilage. See *Triticum*.

FARINA'CEA. (From *farina*, flour.) This term includes all those substances, employed as aliment, called *cerealia*, *legumina*, and *nuces oleosæ*.

FARINA'CEOUS. (*Farinaceus*; from *farina*, flour.) A term given to all articles of food which contain *farina*. See *Farina*.

FARINA'RIUM. See *Alica*.

FA'RREUS. (From *far*, corn.) Scurfy. An epithet of urine, where it deposits a branny sediment.

FA'SCIA. (From *fascis*, a bundle; because, by means of a band, materials are collected into a bundle.) 1. A bandage, fillet, or roller.

2. The tendinous expansions of muscles, which bind parts together, are termed *fasciæ*. See *Aponeurosis*.

FASCIA LATA. A thick and strong tendinous expansion, sent off from the back, and from the tendons of the glutei and adjacent muscles, to surround the muscles of the thigh. It is the thickest on the outside of the thigh and leg, but towards the inside of both becomes gradually thinner. A little below the trochanter major, it is firmly fixed to the linea aspera; and, further down, to that part of the head of the tibia that is next the fibula, where it sends off the tendinous expansion along the outside of the leg. It serves to strengthen the action of the muscles, by keeping them firm in their proper places when in action, particularly the tendons that pass over the joints where this membrane is thickest.

FASCIA'LIS. (From *fascia*, a fillet.) See *Tensor vaginæ femoris*.

FASCIA'TIO. (From *fascia*, a fillet.) The binding up any diseased or wounded part with bandages.

FASCICULARIS. (From *fascis*, a bundle.) Applied to roots which are sessile at their base, and consist of bundles of finger-like processes; as the root of the *Ophris nidus avis*.

FASCICULATUS. Fasciculate. Bundled or clustered. Applied to nerves, stems of plants, leaves, &c. See *Leaf* and *Caulis*.

FASCI'CULUS. (From *fascis*, a bundle.) 1. In pharmacy, a handful.

2. In botany, a fascicule is applied to flowers on little stalks, variously inserted and subdivided, collected into a close bundle, level at the top; as in Sweet-william. It differs from,

1. A *corymb*, in the little stalks coming only from about the apex of the peduncle, and not from its whole length.

2. An *umbel*, from the stalks not coming from a common point.

3. A *cyme*, in not having its principal division umbellate.

FAT. *Adeps.* A concrete oily matter contained in the cellular membrane of animals, of a white, or yellowish colour, with little or no smell, or taste. It differs in different animals in solidity, colour, taste, &c. and likewise in the same animal at different ages. In infancy it is white, insipid, and not very solid; in the adult it is firm and yellowish, and in animals of an advanced age, its colour is deeper, its consistence various, and its taste in general stronger.

The fat appears to be useful in the animal economy principally by its physical properties; it forms a sort of elastic cushion in the orbit upon which the eye moves with facility; in the soles of the feet, and in the hips, it forms a sort of layer, which renders the pressure exerted by the body upon the skin and other soft parts less severe; its presence beneath the skin concurs in rounding the outlines, in diminishing the bony and muscular projections, and in beautifying the form; and as all fat bodies are bad conductors of caloric, it contributes to the preservation of that of the body. Full persons in general suffer little in winter by the cold.

Age, and the various modes of life, have much influence upon the development of this fluid; very young children are generally fat. Fat is rarely abundant in the young man; but the quantity of it increases much towards the age of thirty years, particularly if the nourishment is succulent, and the life sedentary; the abdomen projects, the hips increase in size, as well as the breasts in women. The fat becomes more yellow in proportion as the age is more advanced. Fat meat is nourishing to those that have strong digestive powers. It is used externally, as a softening remedy, and enters into the composition of ointments and plasters.

"Concerning the nature of this important product of animalisation, nothing definite was known, till Chevreuil devoted himself with meritorious zeal and perseverance to its investigation. He has already published in the Annales de Chimie, seven successive memoirs on the subject, each of them surpassing its predecessor in interest. We shall in this article give a brief abstract of the whole.

By dissolving fat in a large quantity of alkohol, and observing the manner in which its different portions were acted upon by this substance, and again separated from it, it is concluded that fat is composed of an *oily substance*, which remains fluid at the ordinary temperature of the atmosphere; and of another *fatty substance* which is much less fusible. Hence it follows, that fat is not to be regarded as a simple principle, but as a combination of the above two principles, which may be separated without alteration. One of these substances melts at about 45°, the other at 100°; the same quantity of alkohol which dissolves 3.2 parts of the *oily substance*, dissolves 1.8 only of the *fatty substance*: the first is separated from the alkohol in the form of an oil; the second in that of small silky needles.

Each of the constituents of natural fat was then saponified by the addition of potassa; and an accurate description given of the compounds which were formed, and of the proportions of their constituents. The *oily substance* became saponified more readily than the *fatty substance*; the residual fluids in both cases contained the sweet oily principle; but the quantity that proceeded from the soap formed of the *oily substance*, was four or five times as much as that from the *fatty substance*. The latter soap was found to contain a much greater proportion of the *pearly matter* than the former, in the proportion of 7.5 to 2.9; the proportion of the *fluid fat* was the reverse, a greater quantity of this being found in the soap formed from the oily substance of the fat.

When the principles which constitute fat unite with potassa, it is probable that they experience a change in the proportion of their elements. This change developes at least three bodies, *margarine*, *fluid fat*, and *the sweet principle*; and it is remarkable, that it takes place without the absorption of any foreign substance, or the disengagement of any of the elements which are separated from each other. As this change is effected by the intermedium of the alkali, we may conclude that the newly formed principles must have a strong affinity for salifiable bases, and will in many respects resemble the acids; and, in fact, they exhibit the leading characters of acids, in reddening litmus, in decomposing the alkaline carbonates to unite to their bases, and in neutralising the specific properties of the alkalies.

Having already pointed out the analogy between the properties of acids and the principles into which fat is converted by means of the alkalies, the next object was to examine the action which other bases have upon fat, and to observe the effect of water, and of the cohesive force of the bases upon the process of saponification. The substances which the author subjected to experiment, were soda, the four alkaline earths, alumina, and the oxides of zinc, copper, and lead. After giving a detail of the processes which he employed with these substances respectively, he draws the following general conclusions:—Soda, barytes, strontian, lime, the oxide of zinc, and the protoxide of lead, convert fat into *margarine*, *fluid fat*, *the sweet principle*, *the yellow colouring principle*, and *the odorous principle*, precisely in the same manner as potassa. Whatever be the base that has been employed, the products of saponification always exist in the same relative proportion. As the above mentioned bases form with margarine and the fluid fat compounds which are insoluble in water, it follows, that the action of this liquid, as a solvent of soap, is not essential to the process of saponification. It is remarkable that the oxides of zinc and of lead, which are insoluble in water, and which produce compounds equally insoluble, should give the same results with potassa and soda,—a circumstance which proves that those oxides have a strong alkaline power. Although the analogy of magnesia to the alkalies is, in other respects, so striking, yet we find that it cannot convert fat into soap under the same circumstances with the oxides of zinc and lead.

It was found that 100 parts of hog's-lard were reduced to the completely saponified state by 16.36 parts of potassa.

The properties of spermaceti were next examined: it melts at about 112°; it is not much altered by distillation; it dissolves readily in hot alkohol, but separates as the fluid cools; the solution has no effect in changing the colour of the tincture of litmus, a circumstance, as it is observed, in which it differs from margarine, a substance which, in many respects, it resembles.—Spermaceti is capable of being saponified by potassa, with nearly the same phenomena as when we submit hog's-lard to the action of potassa, although the operation is effected with more difficulty.

The author's general conclusion respecting the fatty matter of dead bodies is, that even after the lactic acid, the lactates, and other ingredients which are less essential, are removed from it, it is not a simple, ammoniacal soap, but a combination of various fatty substances with ammonia, potassa, and lime. The fatty substances which were separated from alkohol, had different melting points, and different sensible properties. It follows, from Chevreuil's experiments, that the substance which is the least fusible, has more affinity for bases than those which are more so. It is observed, that adipocere possesses the characters of a saponified fat; it is soluble in boiling alkohol in all proportions, reddens litmus, and unites readily to potassa, not only without losing its weight, but without having its fusibility or other properties changed.

Chevreuil has shown, that hog's-lard, in its natural state, has not the property of combining with alkalies; but that it acquires it by experiencing some change in the proportion of its elements. This change being induced by the action of the alkali, it follows that the bodies of the new formation must have a decided affinity for the species of body which has determined it. If we apply this foundation of the theory of saponification to the change into fat which bodies buried in the earth experience, we shall find that it explains the process in a very satisfactory manner. In reality, the fatty matter is the combination of the two adipose substances with ammonia, lime, and potassa: one of these substances has the same sensible properties with margarine procured from the soap of hog's-lard; the other, the orange-coloured oil, excepting its colour, appears to have a strong analogy with the fluid fat. From these circumstances, it is probable that the formation of the fatty matter may be the result of a proper saponification produced by ammonia, proceeding from the decomposition of the muscle, and by the potassa and lime, which proceed from the decomposition of certain salts.

The author remarks, that he has hitherto made use of periphrases when speaking of the different bodies that he has been describing, as supposing that their nature was not sufficiently determined. He now, however, conceives, that he may apply specific names to them, which will both be more commodious, and, at the same time, by being made appropriate, will point out the relation which these bodies bear to each other. The following is the nomenclature which he afterwards adopted:—The crystalline matter of human biliary calculi is named *cholesterine*, from the Greek words χολη, bile, and ϛερεος, solid; spermaceti is named *cetine*, from κητος, a whale; the fatty substance and the oily substance, are named respectively, *stearine* and *elaïne*, from the words ϛεαρ, fat, and ελαιον, oil; margarine, and the fluid fat obtained after saponification, are named *margaric acid* and *oleic acid*, while the term *cetic acid* is applied to what was named saponified spermaceti. The *margarates*, *oleates*, and *cetates*, will be the generic names of the soaps or combinations which these acids are capable of forming by their union with salifiable bases.

Two portions of human fat were examined, one taken from the kidney, the other from the thigh: after some time they both of them manifested a tendency to separate into two distinct substances, one of a solid, and the other of a fluid consistence: the two portions differed in their fluidity and their melting point. These variations depend upon the different proportions of stearine and elaïne; for the concrete part of fat is a combination of the two with an excess of stearine, and the fluid part is a combination with an excess of elaïne. The fat from the other animals was then examined, principally with respect to their melting point and their solubility in alkohol; the melting point was not always the same in the fat of the same species of animal.

Chevreuil next examines the change which is produced in the different kinds of fat respectively by the action of potassa. All the kinds of fat are capable of being perfectly saponified, when excluded from the contact of the air: in all of them there was the production of the saponified fat and the sweet principle; no carbonic acid was produced, and the soaps formed contained no acetic acid, or only slight traces of it. The saponified fats had more tendency to crystallise in needles than the fats in their natural state; they were soluble in all proportions in boiling alkohol of the specific gravity of .821. The solution, like that of the saponified fat of the hog, contained both the margaric and the oleic acids. They were less fusible than the fats from which they were formed: thus, when human fat, after being saponified, was melted, the thermometer became stationary at 95°, when the fluid began to congeal; in that of the sheep, the thermometer fell to 118.5°, and rose to 122°; in that of the ox it remained stationary at 118.5°; and in that of the jaguar at 96.5°.

The method of analysis employed was to expose the different kinds of fat to boiling alkohol, and to suffer the mixture to cool: a portion of the fat that had been dissolved was then separated in two states of combination; one with an excess of stearine was deposited, the other with an excess of elaïne remained in solution. The first was separated by filtration, and by distilling the filtered fluid, and adding a little water towards the end of the operation, we obtain the second in the retort, under the form of an alkoholic aqueous fluid. The distilled alkohol which had been employed in the analysis of human fat had no sensible odour; the same was the case with that which had served for the analysis of the fat of the ox, of the hog, and of the goose. The alkohol which had been employed in the analysis of the fat of the sheep, had a slight odour of candle-grease.

All the soaps of stearine were analysed by the same process as the soap of the fat from which they had been extracted: there was procured from them the pearly super-margarate of potassa and the oleate; but the first was much more abundant than the second. The margaric acid of the stearines had precisely the same capacity for saturation as that which was extracted from the soaps formed of fat. The margaric acid of the stearine of the sheep was fusible at 144°, and that of the stearine of the ox at 143.5°; while the margaric acids of the hog and the goose had nearly the same fusibility with the margaric acid of the fat of these animals.

Chevreuil technically calls spermaceti, *cetine.* In the fifth memoir, in which we have an account of many of the properties of this substance, it was stated, that it is not easily saponified by potassa, but that it is converted by this reagent into a substance which is soluble in water, but has not the saccharine flavour of the sweet principle of oils; into an acid analogous to the margaric, to which the name of *cetic* was applied; and into another acid, which was conceived to be analogous to the oleic. Since he wrote the fifth memoir, the author has made the following observations on this subject:—1. That the portion of the soap of cetine which is insoluble in water, or the cetate of potassa, is in part gelatinous, and in part pearly: 2. That two kinds of crystals were produced from the cetate of potassa which had been dissolved in alkohol: 3. That the cetate of potassa exposed, under a bell glass, to the heat of a stove, produced a sublimate of a fatty matter which was not acid. From this circumstance Chevreuil was led to suspect, that the supposed cetic acid might be a combination, or a mixture of margaric acid, and of a fatty body which was not acid. He accordingly treated a small quantity of it with barytic water, and boiled the soap which was formed in alkohol; the greatest part of it was not dissolved, and the alkoholic solution, when cooled, filtered, and distilled, produced a residuum of fatty matter which was not acid. The suspicion being thus confirmed, Chevreuil determined to subject cetine to a new train of experiments. Being treated with boiling alkohol, a cetine was procured which was fusible at 120°, and a yellow fatty matter which began to become solid at 89.5°, and which at 73.5° contained a fluid oil, which was separated by filtration."—*Ure's Chem. Dict.*

FATU′ITAS. (From *fatuus*, silly.) Fatuity or foolishness.

FAU′CES. (*Faux*, pl. *fauces.*) A cavity behind the tongue, palatine arch, uvula, and tonsils: from which the pharynx, and larynx proceed.

FAU′FEL. Terra japonica, or catechu.

FAUX. (*Faux, cis.* f.) 1. The gorge, or mouth or opening of the gullet.

2. Applied by botanists to the opening of the tube of monopetalous corols. See *Corolla.*

FAVA′GO AUSTRALIS. (From *favus*, a honey-comb; from its resemblance to a honey-comb.) A species of bastard sponge.

FAVOSUS. (From *favus*, a honey-comb.) Honey-comb-like. 1. Applied to some eruptive diseases; as *Lichen favosus*, the secretion in which is cellular and honey-comb-like.

2. To parts of plants, as the receptacle of the onopordium, which has cells like a honey-comb.

FA′VUS. 1. A honey-comb.

2. A species of achor, or foul ulcer.

FE′BRES. (The pleural of *febris.*) An order in the class *Pyrexiæ* of Cullen, characterised by the presence of pyrexia, without primary local affection.

FEBRI′CULA. (Dim. of *febris*, a fever.) A term employed to express a slight degree of symptomatic fever.

FEBRI′FUGA. (From *febrem*, *fugare*, to drive away a fever.) The plant fever-few; lesser centaury.

FE′BRIFUGE. (*Febrifugus*; from *febris*, a fever, and *fugo*, to drive away.) That which possesses the property of abating the violence of any fever.

FEBRIFUGUM CRENII. Regulus of antimony.

FEBRIFUGUM OLEUM. Febrifuge oil. The flowers of antimony, made with salammoniac and antimony sublimed together, and exposed to the air, when they deliquesce.

FEBRIFUGUS PULVIS. Febrifuge powder. The Germans give this name to the pulvis stypticus Helvetii. In England a mixture of oculi cancrorum and emetic tartar, in the proportion of half a drachm and two grains, has obtained the same name; in fevers it is given in doses of gr. iii. to iv.

FEBRIFUGUS SAL. Regenerated marine salt.

FE′BRIS. (*Febris, is.* f.; from *ferveo*, to burn.) A fever. A disease characterised by an increase of heat, an accelerated pulse, a foul tongue and an impaired state of several functions of the body.

FEBRIS ALBA. See *Chlorosis.*

FEBRIS AMPHIMERINA. A quotidian fever.

FEBRIS ANGINOSA. See *Scarlatina anginosa.*

FEBRIS APHTHOSA. See *Aptha.*

FEBRIS ARDENS. Fever attended by a very hot or burning state of the skin. A burning inflammatory fever.

FEBRIS ASSODES. A tertian fever, with extreme restlessness.

FEBRIS BULLOSA. See *Pemphigus.*

FEBRIS CACATORIA. An intermittent fever, with diarrhœa.

FEBRIS CARCERUM. The prison fever.

FEBRIS CASTRENSIS. A camp fever, generally typhus.

FEBRIS CATARRHALIS. A fever, either typhoid, nervous, or synochal, attended with symptoms of catarrh.

Febris cholerica. A fever attended throughout with bilious diarrhœa.

Febris continua. A continued fever. A division of the order *Febres*, in the class *Pyrexiæ* of Cullen. Continued fevers have no intermission, but exacerbations come on usually twice in one day. The genera of continued fever are:

1. *Synocha*, or inflammatory fever, known by increased heat; pulse frequent, strong, and hard; urine high-coloured; senses not much impaired. See *Synocha*.

2. *Typhus*, or putrid-tending fever, which is contagious, and is characterised by moderate heat; quick, weak, and small pulse; senses much impaired, and great prostration of strength. This genus has two species: *Typhus petechialis*, attended with petechiæ; and *Typhus icterodes*, or yellow fever; and of the former there are two varieties: *Typhus mitior*, or nervous fever; and *Typhus gravior*, or putrid fever. See *Febris nervosa*, and *Typhus*.

3. *Synochus*, or mixed fever. See *Synochus*.

Febris elodes. A fever with continual and profuse sweating.

Febris epiala. A fever with a continual sense of coldness. See *Epialus*.

Febris erysipelatosa. See *Erysipelas*.

Febris exanthematica. A fever with an eruption. See *Exanthema*.

Febris flalva. See *Typhus*.

Febris hectica. A genus of disease in the class *Pyrexiæ*, and order *Febris*, of Cullen. It is known by exacerbations at noon, but greater in the evening, with slight remissions in the morning, after nocturnal sweats; the urine depositing a furfuraceo-lateritious sediment; appetite good; thirst moderate. Hectic fever is symptomatic of chlorosis, scrophula, phthisis, diseased viscera, &c.

Febris hungarica. A species of tertian intermittent fever.

Febris hydrodes. A fever with profuse sweats.

Febris inflammatoria. See *Synocha*.

Febris intermittens. An intermittent fever, or ague. A division of the order *Febres* of Cullen, in the class *Pyrexiæ*. Intermittent fevers are known by cold, hot, and sweating stages, in succession, attending each paroxysm, and followed by an intermission or remission. There are three genera of intermitting fevers, and several varieties.

1. *Quotidiana*. A quotidian ague. The paroxysms return in the morning, at an interval of about twenty-four hours.

2. *Tertiana*. A tertian ague. The paroxysms commonly come on at mid-day, at an interval of about forty-eight hours.

3. *Quartana*. A quartan ague. The paroxysms come on in the afternoon, with an interval of about seventy-two hours. The tertian ague is most apt to prevail in the spring, and the quartan in autumn.

Of the quotidian, tertian, and quartan intermittents, there are several varieties and forms; as the double tertian, having a paroxysm every day, with the alternate paroxysms, similar to one another. The double tertian, with two paroxysms every other day. The triple tertian, with two paroxysms on one day, and another on the next. The double quartan, with two paroxysms on the first day, none on the second and third, and two again on the fourth day. The double quartan, with a paroxysm on the first day, another on the second, but none on the third. The triple quartan, with three paroxysms every fourth day. The triple quartan with a paroxysm every day, every fourth paroxysm being similar.

When these fevers arise in the spring of the year, they are called vernal; and when in the autumn, they are known by the name of autumnal. Intermittents often prove obstinate, and are of long duration, in warm climates; and they not unfrequently resist every mode of cure, so as to become very distressing to the patient; and by the extreme debility which they thereby induce, often give rise to other chronic complaints.

It seems to be pretty generally acknowledged, that marsh miasmata, or the effluvia, arising from stagnant water, or marshy ground, when acted upon by heat, are the most frequent exciting cause of this fever. In marshes, the putrefaction of both vegetable and animal matter is always going forward, it is to be presumed; and hence it has been generally conjectured, that vegetable and animal putrefaction imparted a peculiar quality to the effluvia arising from thence. We are not yet acquainted with all the circumstances, which are requisite to render marsh miasma productive of the intermittents; but it may be presumed that a moist atmosphere has a considerable influence in promoting its action. A watery poor diet, great fatigue, long watching, grief, much anxiety, exposure to cold, lying in damp rooms or beds, wearing damp linen, the suppression of some long-accustomed evacuation, or the recession of eruptions, have been ranked among the exciting causes of intermittents; but it is more reasonable to suppose that these circumstances act only by inducing that state of the body, which predisposes to these complaints. By some, it has been imagined that an intermittent fever may be communicated by contagion; but this supposition is by no means consistent with general observation.

One peculiarity of this fever is, its great susceptibility of a renewal from very slight causes, as from the prevalence of an easterly wind, even without the repetition of the original exciting cause. It would appear that a predisposition is left in the habit, which favours the recurrence of the complaint. In this circumstance, intermittents differ from most other fevers, as it is well known that after a continued fever has once occurred, and been removed, the person so affected is by no means so liable to a fresh attack of the disorder, as one in whom it had never taken place.

We have not yet attained a certain knowledge of the proximate cause of an intermittent fever, but a deranged state of the stomach and primæ viæ is that which is most generally ascribed.

Each paroxysm of an intermittent fever is divided into three different stages, which are called the *cold*, the *hot*, and the *sweating stages*, or *fits*.

The *cold* stage commences with languor, a sense of debility and sluggishness in motion, frequent yawning and stretching, and an aversion to food. The face and extremities become pale, the features shrink, the bulk of every external part is diminished, and the skin over the whole body appears constricted, as if cold had been applied to it. At length the patient feels very cold, and universal rigors come on with pains in the head, back, loins, and joints, nausea and vomiting of bilious matter; the respiration is small, frequent and anxious; the urine is almost colourless; sensibility is greatly impaired; the thoughts are somewhat confused; and the pulse is small, frequent, and often irregular. In a few instances, drowsiness and stupor have prevailed in so high a degree as to resemble coma or apoplexy; but this is by no means usual.

These symptoms abating after a short time, the second stage commences with an increase of heat over the whole body, redness of the face, dryness of the skin, thirst, pain in the head, throbbing in the temples, anxiety and restlessness;

the respiration is fuller and more free, but still frequent; the tongue is furred, and the pulse has become regular, hard, and full. If the attack has been very severe, then perhaps delirium will arise.

When these symptoms have continued for some time, a moisture breaks out on the forehead, and by degrees becomes a sweat, and this, at length, extends over the whole body. As this sweat continues to flow, the heat of the body abates, the thirst ceases, and most of the functions are restored to their ordinary state. This constitutes the third stage.

It must, however, be observed, that in different cases these phenomena may prevail in different degrees, and their mode of succession vary; that the series of them may be more or less complete; and that the several stages, in the time they occupy, may be in different proportions to one another.

Such a depression of strength has been known to take place on the attack of an intermittent, as to cut off the patient at once; but an occurrence of this kind is very uncommon.

Patients are seldom destroyed in intermittents from general inflammation, or from a fulness of the vessels either of the brain or of the thoracic viscera, as happens sometimes in a continued fever; but when they continue for any length of time, they are apt to induce other complaints, such as a loss of appetite, flatulency, schirrhus of the liver, dropsical swellings, and general debility, which in the end now and then prove fatal. In warm climates, particularly, intermittents are very apt to terminate in this manner, if not speedily removed; and in some cases, they degenerate into continued fevers. When the paroxysms are of short duration, and leave the intervals quite free, we may expect a speedy recovery; but when they are long, violent, and attended with much anxiety and delirium, the event may be doubtful. Relapses are very common to this fever at the distance of five or six months, or even a year; autumnal intermittents are more difficult to remove than vernal ones, and quartans more so than the other types.

Dissections of those who have died of an intermittent, show a morbid state of many of the viscera of the thorax and abdomen; but the liver and organs concerned in the formation of bile, as likewise the mesentery, are those which are usually most affected.

The treatment of an intermittent fever resolves itself into those means, which may be employed during a poroxysm, to arrest its progress, or to mitigate its violence; and those, which may prevent any return, and effect a permanent cure: this forms of course the more important part of the plan; but it is sometimes necessary to palliate urgent symptoms; and it is always desirable to suspend a poroxysm, if possible, not only to prevent mischief, but also that there may be more time for the use of the most effectual remedies. When therefore a fit is commencing, or shortly expected, we may try to obviate it by some of those means, which excite movements of an opposite description in the system: an emetic will generally answer the purpose, determining the blood powerfully to the surface of the body; or a full dose of opium, assisted by the pediluvium, &c.; æther also, and various stimulant remedies will often succeed, but these may perhaps aggravate, should they not prevent the fit; the cold bath, violent exercise, strong impressions on the mind, &c. have likewise been occasionally employed with effect. Should the paroxysm have already come on, and the cold stage be very severe, the warm bath, and cordial diaphoretics in repeated moderate doses may assist in bringing warmth to the surface: when on the contrary great heat prevails, the antiphlogistic plan is to be pursued; and it may be sometimes advisable, when an organ of importance is much pressed upon, to take some blood locally, or even from the general system, if the patient is plethoric and robust; and where profuse perspirations occur, acidulated drink may be exhibited, with a little wine to support the strength, keeping the surface cool at the same time. In the intermissions, in conjunction with a generous diet, moderate exercise, and other means calculated to improve the vigour of the system; tonics are the remedies especially relied upon. At the head of these we must certainly place the cinchona, which taken largely in substance, will seldom fail to cure the disease, where it is not complicated with visceral affection: in a quotidian an ounce at least should be given between the fits, in a tertian half as much more, and in a quartan two ounces. It will be generally better to clear out the primæ viæ before this remedy is begun with; and various additions may often be required, to make it agree better with the stomach and bowels, particularly aromatics and other stimulants, aperients or small doses of opium, according to circumstances. We must not be content with the omission of a single paroxysm, but continue it till the health appears fully established. In failure of the cinchona, other vegetable tonics may be tried, as the salix, gentian, calumba, and other bitters; or the astringents, as tormentil, galls, &c.; or these variously combined with each other, or with aromatics. The mineral acids are often powerfully tonic, and the sulphuric has been of late stated to have proved very successful in the removal of this disease. Some metallic preparations are also highly efficacious, particularly the liquor arsenicalis, which however is too hazardous a remedy to be employed indiscriminately; it must be given in small doses two or three times a day, and its effects assiduously watched. The sulphate of zinc, and chalybeates, may be used more freely alone, or preferably joined with bitters. Where visceral disease attends, we can hardly succeed in curing the ague, till this be removed; a state of congestion, or inflammatory tendency, may require local bleeding, blistering, purging, &c.; and when there is a more fixed obstruction, particularly in the liver, the cautious use of mercury will be most likely to avail.

FEBRIS LACTEA. Milk fever, which is mostly of the synochus-type attended with much irregularity of mind, and nervousness.

FEBRIS LENTA. See *Febris nervosa.*

FEBRIS LENTICULARIS. A fever, either typhus or synochus, attended by an irruption like small lentils.

FEBRIS MALIGNA. See *Typhus.*

FEBRIS MILIARIS. See *Miliaria.*

FEBRIS MORBILLOSA. See *Rubeola.*

FEBRIS NERVOSA. *Febris lenta nervosa.* The nervous fever. A variety of the *typhus mitior* of Cullen, but by many considered as a distinct disease. It mostly begins with loss of appetite, increased heat and vertigo; to which succeed nausea, vomiting, great languor, and pain in the head, which is variously described, by some like cold water pouring over the top, by others a sense of weight. The pulse, before little increased, now becomes quick, febrile, and tremulous; the tongue is covered with a white crust, and there is great anxiety about the præcordia. Towards the seventh or eighth day, the vertigo is increased, and tinnitus aurium, cophosis, delirium, and a dry and tremulous tongue take place. The disease mostly terminates about the fourteenth or twentieth day. See *Typhus*.

Febris nosocomiorum. The fever of hospitals, mostly the *typhus gravior*.

Febris palustris. The marsh fever.

Febris pestilens. See *Pestis*.

Febris petechialis. See *Typhus*.

Febris putrida. See *Typhus*.

Febris remittens. A remittent fever: a fever with strong exacerbations, which approach in some cases to the nature of a paroxysm of an intermittent, and which follow each other so closely as to leave very little time between. In some, there is a great secretion of bile, when it is called *a bilious* remittent; in others, there is great putrescenty, when it is termed a *putrid* remittent, and so on.

Febris scarlatina. See *Scarlatina*.

Febris synocha. See *Synocha*.

Febris typhodes. See *Typhus*.

Febris urticaria. See *Urticaria*.

Febris variolosa. See *Variola*.

Febris vesiculosa. See *Erysipelas*.

FE'CULA. See *Fæcula*.

FECUNDATION. See *Generation*.

FEL. See *Bile*.

Fel naturæ. See *Aloes*.

FEL-WORT. So called from its bitter taste, like bile. See *Gentiana*.

Felli'culus. The gall-bladder.

Felli'flua passio. See *Cholera*.

Felon. See *Paronychia*.

FELSPAR. An important mineral genus, distributed by Jameson into four species: prismatic felspar; pyramidal felspar; prismato-pyramidal felspar; rhomboidal felspar.

1. The prismatic felspar has nine sub-species,

a. Adularia.

b. Glassy felspar.

c. Ice spar.

d. Common felspar.

e. Labradore felspar.

f. Compact felspar.

g. Clink-stone.

h. Earthy common spar.

i. Porcelain earth.

2. Pyramidal felspar. This embraces the scapolite and elaolite.

3. Prismato-pyramidal felspar. See *Meionite*.

4. Rhomboidal felspar. See *Nepheline*. Chiastolite and sodalite have also been annexed to this species.

Fe'men. (*Quasi ferimen*; from *fero*, to bear: so called because it is the chief support of the body.) The thigh.

FEMINEUS. A flower is termed a female, which is furnished with the pistillum, and not with the stamina; the pistil being considered as the female generative organ.

FEMORAL. (*Femoralis*; from *femur*, the thigh.) Of or belonging to the thigh.

Femora'lis arteria. A continuation of the external iliac along the thigh, from Poupart's ligament to the ham.

FE'MORIS OS. The thigh-bone. A long cylindrical bone, situated between the pelvis and tibia. Its upper extremity affords three considerable processes; these are, the head, the trochanter major, and trochanter minor. The head, which forms about two-thirds of a sphere, is turned inwards, and is received into the acetabulum of the os innominatum, with which it is articulated by enarthrosis. It is covered by a cartilage, which is thick in its middle part, and thin at its edges, but which is wanting in its lower internal part, where a round spongy fossa is observable, to which the strong ligament, usually, though improperly called the *round* one, is attached. This ligament is about an inch in length, flattish, and of a triangular shape, having its narrow extremity attached to the fossa just described, while its broader end is fixed obliquely to the rough surface near the inner and anterior edge of the acetabulum of the os innominatum, so that it appears shorter internally and anteriorly, than it does externally and posteriorly.

The head of the os femoris is supported obliquely, with respect to the rest of the bone, by a smaller part, called the *cervix*, or *neck*, which in the generality of subjects, is about an inch in length. At its basis we observe two oblique ridges, which extend from the trochanter major to the trochanter minor. Of these ridges the posterior one is the most prominent. Around this neck is attached the capsular ligament of the joint, which likewise adheres to the edge of the cotyloid cavity, and is strengthened anteriorly by many strong ligamentous fibres, which begin from the lower and anterior part of the ilium, and spreading broader as they descend, adhere to the capsular ligament, and are attached to the anterior oblique ridge at the bottom of the neck of the femur. Posteriorly and externally, from the basis of the neck of the bone, a large unequal protuberance stands out, which is the *trochanter major*. The upper edge of this process is sharp and pointed posteriorly, but is more obtuse anteriorly. A part of it is rough and unequal, for the insertion of the muscles; the rest is smooth, and covered with a thin cartilaginous crust, between which and the tendon of the glutæus maximus that slides over it, a large bursa mucosa is interposed. Anteriorly, at the root of this process, and immediately below the bottom of the neck, is a small process called *trochanter minor*. Its basis is nearly triangular, having its two upper angles turned towards the head of the femur and the great trochanter, while its lower angle is placed towards the body of the bone. Its summit is rough and rounded. These two processes have gotten the name of *trochanters*, from the muscles that are inserted into them being the principal instruments of the rotatory motion of the thigh. Immediately below these two processes the body of the bone may be said to begin. It is smooth and convex before, but is made hollow behind by the action of the muscles. In the middle of this posterior concave surface is observed a rough ridge, called *linea aspera*, which seems to originate from the trochanters, and extending downwards, divides at length into two branches, which terminate in the tuberosities near the condyles. At the upper part of it, blood-vessels pass to the internal substance of the bone, by a hole that runs obliquely upwards.

The lower extremity of the os femoris is larger than the upper one, and somewhat flattened, so as to form two surfaces, of which the anterior one is broad and convex, and the posterior one narrower and slightly concave. This end of the bone terminates in two large protuberances, called *condyles*, which are united before so as to form a pulley, but are separated behind by a considerable cavity, in which the crural vessels and nerves are placed secure from the compression to which they would otherwise be exposed in the action of bending the leg. Of these two condyles, the external one is the largest; and when the bone is separated from the rest of the skeleton, and placed perpendicularly, the internal condyle projects less forwards, and descends nearly three-tenths of an inch lower than the external one; but in its natural situation, the bone is placed obliquely, so that both condyles are then nearly on a level with each other. At the side of each condyle, externally, there is a tuberosity, the situation of which is similar to that of the condyles of the os humeri. The two branches of the linea aspera terminate in these tuberosities, which are rough, and serve for attachment of ligaments and muscles.

FE'MUR. (*Femur, moris.* n.) The thigh.

FENE'STRA. (From *φαινω, quasi phænestra.*) A window, entry, or hole.

FENESTRA OVALIS. An oblong or elliptical foramen, between the cavity of the tympanum and the vestibulum of the ear. It is shut by the stapes.

FENESTRA ROTUNDA. A round foramen, leading from the tympanum to the cochlea of the ear. It is covered by a membrane in the fresh subject.

FE'NNEL. See *Anethum fœniculum.*

Fennel, hog's. See *Peucedanum.*

FE'NUGREEK. See *Trigonella fœnum græcum.*

FE'RINE. (*Ferinus*, savage or brutal.) A term occasionally applied to any malignant or noxious disease.

FERMENTA'TION. (*Fermentatio, onis.* f.; from *fermento*, to ferment.) When aqueous combinations of vegetable or animal substances are exposed to ordinary atmospherical temperatures, they speedily undergo spontaneous changes, to which the generic term of fermentation has been given. There are several circumstances required in order that fermentation may proceed: such are, 1. A certain degree of fluidity: thus, dry substances do not ferment at all. 2. A certain degree of heat. 3. The contact of air. Chemists, after Boerhaave, have distinguished three kinds of fermentation.

1. The *vinous* or *spirituous*, which affords ardent spirit.

2. The *acetous*, which affords vinegar, or acetic acid.

3. The *putrid* fermentation, or putrefaction, which produces volatile alkali.

I. The conditions necessary for vinous fermentation are: 1. A saccharine mucilage. 2. A degree of fluidity slightly viscid. 3. A degree of heat between 55 and 65 of Fahrenheit. 4. A large mass, in which a rapid commotion may be excited. When these four conditions are united, the vinous fermentation takes place, and is known by the following characteristic phenomena: 1. An intestine motion takes place. 2. The bulk of the mixture then becomes augmented. 3. The transparency of the fluid is diminished by opaque filaments. 4. Heat is generated. 5. The solid parts mixed with the liquor rise and float in consequence of the disengagement of elastic fluid. 6. A large quantity of carbonic acid gas is disengaged in bubbles. All these phenomena gradually cease in proportion as the liquor loses its sweet and mild taste, and it becomes brisk, penetrating, and capable of producing intoxication. In this manner, wine, beer, cider, &c. are made. All bodies which have undergone the spirituous fermentation are capable of passing on to the acid fermentation; but although it is probable that the acid fermentation never takes place before the body has gone through the spirituous fermentation, yet the duration of the first is frequently so short and imperceptible, that it cannot be ascertained. Besides the bodies which are proper for spirituous fermentation, this class includes all sorts of fæcula boiled in water.

II. The conditions required for the acid fermentation are, 1. A heat from 70 to 85 degrees of Fahrenheit. 2. A certain degree of liquidity. 3. The presence of atmospheric air. 4. A moderate quantity of fermentable matter. The phenomena which accompany this fermentation, are an intestine motion, and a considerable absorption of air. The transparent liquor becomes turbid, but regains its limpidity when fermentation is over. The fermented liquor now consists, in a great measure, of a peculiar acid, called the acetic acid, or vinegar. Not a vestige of spirit remains, it being entirely decomposed, but the greater the quantity of spirit in the liquor, previous to the fermentation, the greater will be the quantity of true vinegar obtained. As the ultimate constituents of vegetable matter are oxygen, hydrogen, and carbon; and of animal matter, the same three principles with azote, we can readily understand that all the products of fermentation must be merely new compounds of these three or four ultimate constituents. Accordingly, 100 parts of real vinegar, or acetic acid, are resolvable, by Gay Lussac and Thenard's analysis, into 50.224 carbon + 46.911 hydrogen and oxygen, as they exist in water, + 2.863 oxygen in excess. In like manner, wines are all resolvable into the same ultimate components, in proportions somewhat different. The aëriform results of putrefactive fermentation are in like manner found to be hydrogen, carbon, oxygen, and azote, variously combined, and associated with minute quantities of sulphur and phosphorus. The residuary matter consists of the same principles, mixed with the saline and earthy parts of animal bodies.

Lavoisier was the first philosopher who instituted, on right principles, a series of experiments to investigate the phenomena of fermentation, and they were so judiciously contrived, and so accurately conducted, as to give results comparable to those derived from the more rigid methods of the present day. Since then, Thenard and Gay Lussac have each contributed most important researches. By the labours of these three illustrious chemists, those material metamorphoses, formerly quite mysterious, seem susceptible of a satisfactory explanation.

As sugar is a substance of uniform and determinate composition, it has been made choice of for determining the changes which arise when its solution is fermented into wine or alkohol. Lavoisier justly regarded it as a true vegetable oxide, and stated its constituents to be, 8 hydrogen, 28 carbon, and 64 oxygen, in 100 parts. By two different analyses of Berzelius, we have,

Hydrogen,	6.802	6.891
Carbon,	44.115	42.704
Oxygen,	49.083	50.405
	100.000	100.000

Gay Lussac and Thenard's analyses gives,

Hydrogen,	6.90	57.53 water,
Oxygen,	50.63	
Carbon,	42.47	42.47
	100.00	100.00

It has been said, that sugar requires to be dissolved in at least 4 parts of water, and to be mixed with some yeast, to cause its fermentation to commence. But this is a mistake. Syrup stronger than the above will ferment in warm weather, without addition. If the temperature be low, the syrup weak, and no yeast added, acetous fermentation alone will take place. To determine the vinous, therefore, we must mix certain proportions of saccharine matter, water, and yeast, and place them in a proper temperature.

To observe the chemical changes which occur, we must dissolve 4 or 5 parts of pure sugar in 20 parts of water, put the solution into a matrass, and add 1 part of yeast. Into the mouth of the matrass a glass tube must be luted, which is recurved, so as to dip into the mercury of a pneumatic trough. If the apparatus be now placed in a temperature of from 70° to 80°, we shall speedily observe the syrup to become muddy, and a multitude of air bubbles to form all around the ferment. These unite, and attaching themselves to particles of the yeast, rise along with it to the surface, forming a stratum of froth. The yeasty matter will then disengage itself from the air, fall to the bottom of the vessel, to reacquire buoyancy a second time by attached air bubbles, and thus in succession. If we operate on 3 or 4 ounces of sugar, the fermentation will be very rapid during the first ten or twelve hours; it will then slacken, and terminate in the course of a few days. At this period the matter being deposited which disturbed the transparency of the liquor, this will become clear.

The following changes have now taken place: 1. The sugar is wholly, and the yeast partially, decomposed. 2. A quantity of alkohol and carbonic acid, together nearly in weight to the sugar, is produced. 3. A white matter is formed, composed of hydrogen, oxygen, and carbon, equivalent to about half the weight of the decomposed ferment. The carbonic acid passes over into the pneumatic apparatus; the alkohol may be separated from the vinous liquid by distillation, and the white matter falls down to the bottom of the matrass with the remainder of the yeast.

The quantity of yeast decomposed is very small. 100 parts of sugar require, for complete decomposition, only two and a half of that substance, supposed to be in a dry state. It is hence very probable, that the ferment, which has a strong affinity for oxygen, takes a little of it from the saccharine particles, by a part of its hydrogen and carbon, and thus the equilibrium being broken between the constituent principles of the sugar, these so react on each other, as to be transformed into alkohol and carbonic acid. If we consider the composition of alkohol, we shall find no difficulty in tracing the steps of this transformation.

Neglecting the minute products which the yeast furnishes, in the act of fermentation, let us regard only the alkohol and carbonic acid. We shall then see, on comparing the composition of sugar to that of alkohol, that to transform sugar into alkohol, we must withdraw from it one volume of vapour of carbon, and one volume of oxygen, which form by their union one volume of carbonic acid gas. Finally, let us reduce the volumes into weights, we shall find, that 100 parts of sugar ought to be converted, during fermentation, into 51.55 of alkohol, and 48.45 of carbonic acid.

When it is required to preserve fermented liquors in the state produced by the first stage of fermentation, it is usual to put them into casks before the vinous process is completely ended; and in these closed vessels a change very slowly continues to be made for many months, and perhaps for some years.

But if the fermentative process be suffered to proceed in open vessels, more especially if the temperature be raised to 90 degrees, the acetous fermentation comes on. In this, the oxygen of the atmosphere is absorbed; and the more speedily in proportion as the surfaces of the liquor are often changed by lading it from one vessel to another. The usual method consists in exposing the fermented liquor to the air in open casks, the bung-hole of which is covered with a tile to prevent the entrance of the rain. By the absorption of oxygen, which takes place, the inflammable spirit becomes converted into an acid. If the liquid be then exposed to distillation, pure vinegar comes over instead of ardent spirit.

III. When the spontaneous decomposition is suffered to proceed beyond the acetous process, the vinegar becomes viscid and foul; air is emitted with an offensive smell; volatile alkali flies off; an earthy sediment is deposited; and the remaining liquid, if any, is mere water. This is the putrefactive process. See also *Putrefaction.*

FERME'NTUM. (*Quasi fervimentum,* from *ferveo,* to work.) Yeast.

Fermentum cerevisiæ. Yeast; Barm; the scum which collects on beer while fermenting, and has the property of exciting that process in various other substances. Medicinally it is antiseptic and tonic; and has been found useful internally in the cure of typhus fever attended with an obvious tendency to putrefaction in the system with petechiæ, vibices, and the like: the best way to administer it, is to mix a fluid ounce with seven of strong beer, and give three table-spoonsful to an adult every three or four hours. Externally, it is used in the fermenting cataplasm.

FERN. See *Filix* and *Polypodium.*

Fern, male. See *Polypodium filix mas.*

Fern, female. See *Pteris aquilina.*

FERNEL, John, was born at Claremont, near the end of the 15th century. He went at the age of 19 to prosecute his studies at Paris, and distinguished himself so much, that, after taking the degree of master of arts, he was chosen professor of dialectics in his college. His application then became intense, till a quartan ague obliged him to seek his native air: and on his return to Paris, he determined on the medical profession, and taught philosophy for his support, till in 1530, he took his doctor's degree. Soon after he married, and speedily got into extensive practice; and at length was made physician to the Dauphin, who afterwards became Henry II. He was obliged to accompany that monarch in his campaigns, yet he still, though at the age of sixty, seldom passed a day without writing. But in 1558, having lost his wife of a fever, he did not long survive her. His works are numerous on philosophical, as well as medical subjects: of the latter, the most esteemed were his "Medicina," dedicated to Henry II., and a posthumous treatise on fevers.

Ferrame'ntum. An instrument made of iron.

FERRO-CHYAZIC ACID. (*Acidum ferrochyazicum; chyazicum,* from the initial letters of carbon, hydrogen, and azote.) An acid obtained by Porrett by adding to a solution of ferro-cyanite of barytes, sulphuric acid just enough to precipitate the barytes. It has a pale yellow colour, no smell, and is decomposed by gentle heat or strong light, in which case hydrocyanic acid is formed, and white hydrocyanite of iron is deposited, which becomes blue by exposure.

FERRO-CYANATE. A compound of ferroprussic acid with salifiable bases.

FERRO-CYANIC ACID. See *Ferro-prussic acid.*

FERROPRUSSIC ACID. *Acidum ferroprussicum. Acidum ferro-cyanicum.* Into a solution of the amber-coloured crystals, usually called prussiates of potassa, pour hydro-sulphuret of barytes, as long as any precipitate falls. Throw the whole on a filter, and wash the precipitate with cold water. Dry it; and having dissolved 100 parts in cold water, add gradually thirty of concentrated sulphuric acid; agitate the mixture, and set it aside to repose. The supernatant liquid is ferro-prussic acid, called by Porrett, who had the merit of discovering it, ferruretted chyazic acid.

It has a pale lemon yellow colour, but no smell. Heat and light decompose it. Hydrocyanic acid is then formed, and white ferroprussiate of iron, which soon becomes blue. Its affinity for the bases enables it to displace acetic acid, without heat, from the acetates, and to form ferroprussiates.

FE'RRUM. (*Ferrum, i. neut.*; the etymology uncertain.) Iron. See *Iron.*

Ferrum ammoniatum. Ammoniated iron; formerly known by the names of *flores martiales; flores salis ammoniaci martiales; ens martis; ens veneris Boylei; sal martis muriaticum sublimatum,* and lately by the title of *ferrum ammoniacale.* Take of subcarbonate of iron, muriate of ammonia, of each a pound. Mix them intimately, and sublime by immediate exposure to a strong fire; lastly, reduce the sublimed ammoniated iron to powder. This preparation is astringent and deobstruent, in doses from three to fifteen grains, or more in the form of bolus or pills, prepared with some gum. It is exhibited in most cases of debility, in chlorosis, asthenia, menorrhagia, intermittent fevers, &c. This or some other strong preparation of iron, as the Tinct. ferri muriatis, Mr. Cline is wont to recommend in scirrhous affections of the breast. See *Tinctura ferri ammoniati.*

Ferrum tartarizatum. Tartarized iron. A tartrate of potassa and iron; formerly called *tartarus chalybeatus; mars solubilis; ferrum potabile.* Take of iron, a pound; supertartrate of potassa, powdered, two pounds; water a pint. Rub them together; and expose them to the air in a broad glass vessel for eight days, then dry the residue in a sand bath, and reduce it to a very fine powder. Add to this powder a pint more water, and expose it for eight days longer, then dry it, and reduce it to a very fine powder. Its virtues are astringent and tonic, and it forms in solution an excellent tonic fomentation to contusions, lacerations, distortions, &c. Dose from ten grains to half a drachm.

Ferri alkalini liquor. Solution of alkaline iron. Take of iron, two drachms and a half; nitric acid, two fluid ounces; distilled water, six fluid-ounces; solution of subcarbonate of potassa, six fluid-ounces. Having mixed the acid and water, pour them upon the iron, and when the effervescence has ceased, pour off the clear acid solution; add this gradually, and at intervals, to the solution of subcarbonate of potassa, occasionally shaking it, until it has assumed a deep brown-red colour, and no further effervescence takes place. Lastly, set it by for six hours, and pour off the clear solution. This preparation was first described by Stael, and called tinctura martis alkalina, and is now introduced in the London Pharmacopœia as affording a combination of iron distinct from any other, and often applicable to practice. The dose is from half a drachm to a drachm.

Ferri carbonas. See *Ferri subcarbonas.*

Ferri limatura purificata. Purified iron filings. These possess tonic, astringent, and deobstruent virtues, and are calculated to relieve chlorosis and other diseases in which steel is indicated, where acidity in the primæ viæ abounds.

Ferri rubigo. See *Ferri subcarbonas.*

Ferri subcarbonas. *Ferri carbonas; Ferrum præcipitatum,* formerly called *chalybis rubigo præparata* and *ferri rubigo.* Subcarbonate of iron. Take of sulphate of iron, eight ounces; subcarbonate of soda, six ounces; boiling water, a gallon. Dissolve the sulphate of iron and subcarbonate of soda separately, each in four pints of water; then mix the solutions together and set it by, that the precipitated powder may subside; then having poured off the supernatant liquor, wash the subcarbonate of iron with hot water, and dry it upon bibulous paper in a gentle heat. It possesses mild corroborant and stimulating properties, and is exhibited with success in leucorrhœa, ataxia, asthenia, chlorosis, dyspepsia, rachitis, &c. Dose from two to ten grains.

Ferri sulphas. Sulphate of iron; formerly called *sal martis, vitriolum martis, vitriolum ferri,* and *ferrum vitriolatum.* Green vitriol. Take of iron, sulphuric acid, of each by weight, eight ounces; water, four pints. Mix together the sulphuric acid and water in a glass vessel, and add thereto the iron; then after the effervescence has ceased, filter the solution through paper, and evaporate it until crystals form as it cools. Having poured away the water, dry these upon bibulous paper. This is an excellent preparation of iron, and is exhibited, in many diseases, as a styptic, tonic, astringent, and anthelmintic. Dose from one grain to five grains.

FERRURETTED CHYAZIC ACID. See *Ferro-prussic acid.*

Fersæ. The measles.

Fertile flower. See *Flos.*

FE'RULA. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; order, *Digynia.*

Ferula africana galbanifera. The galbanum plant. See *Bubon galbanum.*

Ferula assafœtida. The systematic name of the assafœtida plant. *Assafœtida. Hingiseh* of the Persians. *Altiht* of the Arabians. By some thought to be the σιλφιον, vel οπος σιλφιου of Dioscorides, Theophrastus, and Hippocrates. *Laser et laserpitium* of the Latins. *Ferula assafœtida—foliis alternatim sinuatis, obtusis,* of Linnæus. This plant, which affords us the assafœtida of the shops, grows plentifully on the mountains in the provinces of Chorassan and Laar, in Persia.

The process of obtaining it is as follows: the earth is cleared away from the top of the roots of the oldest plants; the leaves and stalks are then twisted away, and made into a covering, to screen the root from the sun; in this state the root is left for forty days, when the covering is removed, and the top of the root cut off transversely; it is then screened again from the sun for forty-eight hours, when the juice it exudes is scraped off, and exposed to the sun to harden. A second transverse section of the root is made, and the exudation suffered to continue for forty-eight hours, and then scraped off. In this manner it is eight times repeatedly collected in a period of six weeks. The juice thus obtained has a bitter, acrid, pungent taste, and is well known by its peculiar nauseous smell, the strength of which is the surest test of its goodness. This odour is extremely volatile, and of course the drug loses much of its efficacy by keeping. It is brought to us in large irregular masses, composed of various little shining lumps, or grains, which are partly of a whitish colour, partly reddish, and partly of a violet hue. Those masses are accounted the best which are clear, of a pale reddish colour, and variegated with a great number of elegant white tears. This concrete juice consists of two-thirds of gum, and one-third of resin and volatile oil, in which its taste and smell reside. It yields all its virtues to alkohol. Triturated with water, it forms a milk-like mixture, the resin being diffused by the medium of the gum. Distilled with water, it affords a small quantity of essential oil. It is the most powerful of all the fœtid gums, and is a most valuable remedy. It is most commonly employed in hysteria, hypochondriasis, some symptoms of dyspepsia, flatulent colics, and in most of those diseases termed nervous, but its chief use is derived from its antispasmodic effects; and it is thought to be the most powerful remedy we possess, for those peculiar convulsive and spasmodic affections, which often recur in the first of these diseases, both taken into the stomach and in the way of enema. It is also recommended as an emmenagogue, anthelmintic, antiasthmatic, and anodyne. Dr. Cullen prefers it as an expectorant to gum ammoniacum. Where we wish it to act immediately as an antispasmodic, it should be used in a fluid form, as that of tincture, from half a drachm to two drachms. When given in the form of a pill, or triturated with water, its usual dose is from five to twenty grains. When in the form of enema, one or two drachms are to be diffused in eight ounces of warm milk or water. It is sometimes applied externally as a plaster and stimulating remedy, in hysteria, &c.

FERULA MINOR. All-heal of Æsculapius. This plant is said to be detergent.

FERULA'CCA. See *Bubon galbanum.*

FEVER. See *Febris.*

FEVERFEW. See *Matricaria.*

FI'BER. (From *fiber*, extreme, because it resides in the extremities of lakes and rivers.) The beaver. See *Castor fiber.*

FIBRE. *Fibra.* A very simple filament. It is owing to the difference in the nature and arrangements of the fibres that the structure of the several parts of animals and vegetables differ: hence the barks, woods, leaves, &c. of vegetables, and the cellular structure, membranes, muscles, vessels, nerves, and, in short, every part of the body, has its fibres variously constituted and arranged, so as to form these different parts.

Fibre muscular. See *Muscular fibre.*

FIBRIL. (*Fibrila*, diminutive of *fibra.*) A small thread-like fibre: applied to the little roots which are given off from radicles.

FI'BRIN. "A peculiar organic compound found both in vegatables and animals. Vauquelin discovered it in the juice of the papaw-tree. It is a soft solid, of a greasy appearance, insoluble in water, which softens in the air, becoming viscid, brown, and semi-transparent. On hot coals it melts, throws out greasy drops, crackles, and evolves the smoke and odour of roasting meat. Fibrin is procured, however, in its most characteristic state from animal matter. It exists in chyle; it enters into the composition of blood; of it, the chief part of muscular flesh is formed; and hence it may be regarded as the most abundant constituent of the soft solids of animals.

To obtain it, we may beat blood as it issues from the veins with a bundle of twigs. Fibrin soon attaches itself to each stem, under the form of long reddish filaments, which become colourless by washing them with cold water. It is solid, white, insipid, without smell, denser than water, and incapable of affecting the hue of litmus or violets. When moist it possesses a species of elasticity; by desiccation it becomes yellowish, hard, and brittle. By distillation we can extract from it much carbonate of ammonia, some acetate, a fœtid brown oil, and gaseous products; while there remains in the retort a very luminous charcoal, very brilliant, difficult of incineration, which leaves, after combustion, phosphate of lime, a little phosphate of magnesia, carbonate of lime, and carbonate of soda.

Cold water has no action on fibrin. Treated with boiling water, it is so changed as to lose the property of softening and dissolving in acetic acid. The liquor filtered from it, yields precipitates with infusion of galls, and the residue is white, dry, hard, and of an agreeable taste.

When kept for some time in alkohol of 0.810, it gives rise to an adipocerous matter, having a strong and disagreeable odour. This matter remains dissolved in the alkohol, and may be precipitated by water. Æther makes it undergo a similar alteration, but more slowly. When digested in weak muriatic acid, it evolves a little azote, and a compound is formed, hard, horny, and which, washed repeatedly with water, is transformed into another gelatinous compound. This seems to be a neutral muriate, soluble in hot water; whilst the first is an acid muriate, insoluble even in boiling water. Sulphuric acid, diluted with six times its weight of water, has similar effects. When not too concentrated, nitric acid has a very different action on fibrin. For example, when its sp. gr. is 1.25, there results from it at first a disengagement of azote, while the fibrin becomes covered with fat, and the liquid turns yellow. By digestion of twenty-four hours, the whole fibrin is attacked, and converted into a pulverulent mass of lemon-yellow colour, which seems to be composed of a mixture of fat and fibrin, altered and intimately combined with the malic and nitric or nitrous acids. In fact, if we put this mass on a filter, and wash it copiously with water, it will part with a portion of its acid, will preserve the property of reddening litmus, and will take an orange hue. On treating it afterwards with boiling alkohol, we dissolve the fatty matter; and putting the remainder in contact with chalk and water, an effervescence will be occasioned by the escape of carbonic acid, and malate or nitrate of lime will remain in solution.

Concentrated acetic acid renders fibrin soft at ordinary temperatures, and converts it by the aid of heat into a jelly, which is soluble in hot water, with the disengagement of a small quantity of azote. This solution is colourless, and possesses little taste. Evaporated to dryness, it leaves a transparent residue, which reddens litmus paper, and which cannot be dissolved even in boiling water, but by the medium of more acetic acid. Sulphuric, nitric, and muriatic acids, precipitate the animal matter, and form acid combinations. Potassa, soda, ammonia, effect likewise the precipitation of this matter, provided we do not use too great an excess of alkali; for then the precipitated matter would be redissolved. Aqueous potassa and soda gradually dissolve fibrin in the cold, without occasioning any perceptible change in its nature; but with heat they decompose it, giving birth to a quantity of ammoniacal gas, and other usual animal products. Fibrin does not putrefy speedily when kept in water. It shrinks on exposure to a considerable heat, and emits the smell of burning horn. It is composed, according to the analysis of Gay Lussac, and Thenard, of

Carbon,	53.360	
Azote,	19.934	
Oxygen,	19.685	22.14 water,
Hydrogen,	7.021	4.56 hydrogen.

FIBROLITE. A crystallised mineral harder than quartz, of a white or grey colour, found in the Carnatic, and composed of alumina, silica, and iron.

FIBROSUS. (From *fibre*, a fibre.) Fibrous. A term frequently used in anatomy to express the texture of parts. In botany, its meaning is the same, and is applied to roots and other parts, as those of grasses, &c.

FI'BULA. (*Quasi figilula;* from *figo,* to fasten: so named because it joins together the tibia and the muscles.) A long bone of the leg, situated on the outer side of the tibia, and which forms, at its lower end, the outer ankle. Its upper extremity is formed into an irregular head, on the inside of which is a slightly concave articulating surface, which, in the recent subjects, is covered with cartilage, and receives the circular flat surface under the edge of the external cavity of the tibia. This articulation is surrounded by a capsular ligament, which is farther strengthened by other strong ligamentous fibres, so as to allow only a small motion backwards and forwards.—Externally, the head of the fibula is rough and protuberant; serving for the attachment of ligaments, and for the insertion of the biceps cruris muscle.—Immediately below it, on its inner side, is a tubercle, from which a part of the gastrocnemius internus has its origin. Immediately below this head the body of the bone begins. It is of a triangular shape, and appears as if it were slightly twisted at each end, in a different direction. It is likewise a little curved inwards and forwards. This curvature is in part owing to the action of muscles; and in part perhaps to the carelessness of nurses.—Of the three angles of the bone, that which is turned towards the tibia is the most prominent, and serves for the attachment of the interosseous ligament, which, in its structure and uses, resembles that of the fore-arm, and, like that, is a little interrupted above and below. The three surfaces of the bone are variously impressed by different muscles. About the middle of the posterior surface is observed a passage for the medullary vessels, slanting downwards. The lower end of the fibula is formed into a spongy, oblong head, externally rough and convex, internally smooth and covered with a thin cartilage, where it is received by the external triangular depression at the lower end of the tibia. This articulation, which resembles that of its upper extremity, is furnished with a capsular ligament, and farther strengthened by ligamentous fibres, which are stronger and more considerable than those before described. They extend from the tibia to the fibula, in an oblique direction, and are more easily discernible before than behind. Below this the fibula is lengthened out, so as to form a considerable process, called *malleolus externus,* or the outer ankle. It is smooth, and covered with cartilage on the inside, where it is contiguous to the astragalus, or first bone of the foot. At the lower and inner part of this process, there is a spongy cavity, filled with fat; and a little beyond this, posteriorly, is a cartilaginous groove, for the tendons of the peroneus longus and peroneus brevis, which are here bound down by the ligamentous fibres that are extended over them.

The principal uses of this bone seem to be, to afford origin and insertion to muscles, and to contribute to the articulation of the leg with the foot.

FICA'RIA. (From *ficus,* a fig; so called from its likeness.) See *Ranunculus ficaria.*

Fica'tio. (From *ficus,* a fig.) A tuberculous disease, near the anus and pudenda.

FICOIDE'A. *Ficoides.* Resembling a fig. A name of the house-leek. See *Sempervivum tectorium.*

FI'CUS. 1. A fleshy substance about the anus, in figure resembling a fig.

2. The name of a genus of plants in the Linnæan system. Class, *Polygamia;* Order, *Diœcia.* The fig-tree.

Ficus carica. The systematic name of the fig-tree. *Carica; Ficus; Ficus vulgaris; Ficus communis.* Ευκη of the Greeks. French figs are, when completely ripe, soft, succulent, and easily digested, unless eaten in immoderate quantities, when they are apt to occasion flatulency, pain of the bowels and diarrhœa. The dried fruit, which is sold in our shops, is pleasanter to the taste, and more wholesome and nutritive. They are directed in the *decoctum hordei compositum,* and in the *confectio sennæ.* Applied externally, they promote the suppuration of tumours; hence they have a place in maturating cataplasms; and are very convenient to apply to the gums, and, when boiled with milk, to the throat.

Ficus indica. See *Lacca.*

Fiddle-shaped. See *Leaf.*

Fidicina'les. (*Fidicinalis,* sc. *musculus.*) See *Lumbricales.*

FIENUS, Thomas, was son of a physician of Antwerp, and born in 1567. After studying at Leyden and Bologna, he was invited at the age of 26, to be one of the medical professors at Louvaine, where he took his degrees. With the exception of one year, during which he attended the Duke of Bavaria, he remained in that office till his death in 1631. Besides his great abilities in medicine and surgery, he was distinguished for his knowledge of natural history, the learned languages, and the mathematics. He has left several works: the chief of which is termed "Libri Chirurgici XII." treating of the principal operations; it passed through many editions. His father, *John,* was author of a well received treatise, "De Flatibus."

FIG. See *Ficus carica.*

FIGURESTONE. Bildstein. *Agalmatolite.* A massive mineral of a grey colour, or brown flesh-red, and sometimes spotted, or with blue veins; unctuous to the touch, and yielding to the nail. It comes from China, cut into grotesque figures. It differs from steatite in wanting the magnesia. It is also found in Transylvania, and in Wales.

FIGWORT. See *Ranunculus ficaria.*

FILA'GO. (From *filum,* a thread, and *ago,* to produce or have to do with, in allusion to the cottony web connected with every part of the plant.) Cud or cotton-weed; formerly used as an astringent.

FI'LAMENT. (*Filamentum;* from *filum,* a thread.) 1. A term applied in anatomy to a small thread-like portion adhering to any part, and frequently synonymous with fibre. See *Fibre.*

2. The *stamen* of a flower consists of the filament, anther, and pollen. The filament is the column which supports the anther.

From its *figure* it is called,

1. *Capillary;* as in *Plantago.*

2. *Filiform;* as in *Scilla maritima.*

3. *Flat;* as in *Allium cepa.*

4. *Dilatate,* spreading laterally; as in *Ornithogalum umbellatum.*

5. *Pedicellate,* affixed transversely to a little stalk; as in *Salvia.*

6. *Bifid,* having two; as in *Stemodia.*

7. *Bifurced;* as in *Prunella.*

8. *Multifid;* as in *Carolina princeps.*

9. *Dentate;* as in *Rosmarinus officinalis.*

10. *Nicked;* as in *Allium cepa.*

11. *Lanceolate;* as in *Ornithogalum pyrenaicum.*

12. *Castrate,* the anther naturally wanting; as in *Gratiola officinalis.*

13. *Subulate;* as in *Tulipa gesneriani.*

From the *pubescence,*

1. *Barbate,* bearded: as in *Lycium.*

2. *Lanate,* woolly; as in *Verbascum thapsus.*

3. *Pilose;* as in *Anthericum frutescens.*

4. *Gland-bearing;* as in *Laurus* and *Rheum.*

From its direction,

1. *Erect;* as in *Tulipa gesneriana.*

2. *Incurved;* curved inward, and a little bent.

3. *Declinate;* as in *Hemerocalis fulva.*

4. *Connivent;* as in *Physalis alkekengi.*

From its concretion,

1. *Liberate,* free, no where adhering; as in *Nicotiana tabacum.*

2. *Connate,* adhering at their base; as in *Malva sylvestris,* and *Alcearosea.*

From its insertion,

1. *Receptaculine,* inserted into the receptaculum; as in *Papaver somniferum.*

2. *Corolline,* as in *Verbascum thapsus,* and *Nerium oleander.*

3. *Calicine;* as in *Pyrus malus,* and *Mespilus germanica.*

4. *Styline;* as in the *Orchides.*

5. *Nectorine;* as in *Pancratium declinatum.*

From its length, it is said to be very *long;* as in *Plantago major;* very *short* in *Jasminum* and *Vinca;* and *unequal,* some long, some short; as in *Cheiranthus cheiri.*

FILARIA. The name of a genus of intestinal worms.

FILE′LLUM. (From *filum,* a thread; because it resembles a string.) The frænum of the penis and tongue.

FILE′TUM. (From *filum,* a thread; named from its string-like appearance.) The frænum of the tongue and penis.

FILICES. (*Filix, cis.* f.; from *filum,* a thread.) Ferns. One of the families, or natural tribes into which the whole vegetable kingdom is divided. They are defined plants which bear their flower and fruit on the back of the leaf or stalk, which is termed *frons.*

FILI′CULA. (Dim. of *filix,* fern; a small sort of fern: or from *filum,* a thread, which it resembles.) Common maiden-hair. See *Adianthum capillus veneris.*

FILIFORMIS. Filiform, thread-like: applied to many parts of animals and vegetables from their resemblance.

FILIPE′NDULA. (From *filum,* a thread, and *pendeo,* to hang: so named because the numerous bulbs of its roots hang, as it were by small threads.) See *Spiræa filipendula.*

FILIPENDULA AQUATICA. Water-dropwort; the *Œnanthe fistulosa* of Linnæus.

FILIUS ANTE PATREM. Any plant, the flower of which comes out before the leaf; as coltsfoot.

FI′LIX. (From *filum,* a thread; so called from its being cut, as it were, in slender portions, like threads.) Fern. See *Polypodium.*

FILIX ACULEATA. See *Polypodium aculeatum.*

FILIX FLORIDA. See *Osmunda regalis.*

FILIX FŒMINA. See *Pteris aquilina.*

FILIX MAS. See *Polypodium filix mas.*

FILTRA′TION. (*Filtratio;* from *filtrum,* a strainer.) An operation, by means of which a fluid is mechanically separated from consistent particles merely mixed with it. It does not differ from straining.

An apparatus fitted up for this purpose is called a filter. The form of this is various, according to the intention of the operator. A piece of tow, or wool, or cotton, stuffed into the pipe of a funnel, will prevent the passage of grosser particles, and by that means render the fluid clearer which comes through. Sponge is still more effectual. A strip of linen rag wetted and hung over the side of a vessel containing a fluid, in such a manner as that one end of the rag may be immersed in the fluid, and the other end may remain without, below the surface, will act as a syphon, and carry over the clearer portion. Linen or woollen stuffs may either be fastened over the mouths of proper vessels, or fixed to a frame, like a sieve, for the purpose of filtering. All these are more commonly used by cooks and apothecaries than by philosophical chemists, who, for the most part, use the paper called cap paper, made up without size.

As the filtration of considerable quantities of fluid could not be effected at once without breaking the filter of paper, it is found requisite to use a linen cloth, upon which the paper is applied and supported.

Precipitates and other pulverulent matters are collected more speedily by filtration than by subsidence. But there are many chemists who disclaim the use of this method, and avail themselves of the latter only, which is certainly more accurate, and liable to no objection, where the powders are such as will admit of edulcoration and drying in the open air.

Some fluids, as turbid water, may be purified by filtering through sand. A large earthen funnel, or stone bottle with the bottom beaten out, may have its neck loosely stopped with small stones, over which smaller may be placed, supporting layers of gravel increasing in fineness, and lastly covered to the depth of a few inches with fine sand all thoroughly cleansed by washing. This apparatus is superior to a filtering stone, as it will cleanse water in large quantities, and may readily be renewed when the passage is obstructed, by taking out and washing the upper stratum of sand.

A filter for corrosive liquors may be constructed, on the same principles, of broken and pounded glass.—*Ure's Chem. Dict.*

FI′LTRUM. A filter, straining or filtering instrument.

FILUM. A thread or filament.

FILUM ARSENICALE. Corrosive sublimate.

FI′MBRIA. (A fringe, *quasi fimbria;* from *finis,* the extremity.) A fringe. 1. A term used by anatomists to curled membraneous productions. See *Fimbriæ.*

2. In botany, it is applied to the dentate or fringe-like ring of the operculum of mosses, by the elastic power of which the operculum is displaced. See *Peristomium.*

FIMBRIÆ. (*Fimbria,* a fringe. *Quasi finibria;* from *finis,* the extremity.) The extremities of the Fallopian tubes. See *Uterus.*

FINCKLE. See *Anethum fœniculum.*

Fingered leaf. See *Leaf.*

FIORITE. See *Pearl sinter.*

FIR. See *Pinus.*

Fir balsam. See *Pinus balsamea.*

Fir, Canada. See *Pinus balsamea.*

Fir, Norway spruce. See *Pinus abies.*

Fir, Scotch. See *Pinus sylvestris.*

Fir, silver. See *Pinus picea.*

FIRE. *Ignis.* A very simple and active element, the principal agent in nature to balance the power and natural effect of attraction. The most useful acceptation of the word fire comprehends *heat* and *light.* There have been several theories proposed respecting fire, but no one as yet is fully established. See *Caloric* and *Light.*

FIRMI′SIUM MINERALIUM. Antimony.

FISCHER, JOHN ANDREW, son of an apothecary at Erfurt, was born in 1667. He graduated there, and was appointed in succession to several professorships; but that of pathology and the practice of medicine he did not receive till the age of 48. He acquired considerable reputation in his profession; and he had been ten years physician to the court of Mayence when he died in 1729. Among several minor works he was author of some of greater importance; as the "Consilia Medica," in three volumes; the "Responsa Practica," and a Synopsis of Medicine, facetiously termed "Illias in Nuce."

FISH-GLUE. See *Ichthyocolla*.

FISSURA. A fissure. 1. That species of fracture in which the bone is slit, but not completely divided.

2. A name given to a deep and long depression in a part.

FISSURA MAGNA SYLVII. The anterior and middle lobes of the cerebrum on each side are parted by a deep narrow sulcus, which ascends obliquely backwards from the temporal ala of the os sphenoides, to near the middle of the os parietale, and this sulcus is thus called.

FISSUS. Cleft, cloven. Applied to leaves, and pods, *folia fissa*, that are, as it were, cut into fissures or straight segments. See *Leaf*.

FISTIC-NUT. See *Pistachia vera*.

FI'STULA. (*Quasi fusula*; from *fundo*, to pour out; or from its similarity to a pipe, or reed.) *Eligii morbus*. A term in surgery, applied to a long and sinuous ulcer that has a narrow opening, and which sometimes leads to a larger cavity, and has no disposition to heal.

FISTULA'RIA. (From *fistula*, a pipe so called because its stalk is hollow.) Staves-acre. See *Delphinium staphisagria*.

FIXED. In chemistry, the term fixed bodies is applied to those substances which cannot be caused to pass by a strong rarefaction from the solid or liquid state of an elastic fluid.

Fixed air. See *Carbonic acid*.

FIXITY. The property by which bodies resist the action of heat, so as not to rise in vapour.

FLAG. See *Acorus* and *Iris*.

FLAGELLIFORMIS. Whip-like. A term applied to a stem that is long and pliant, whiplike; as that of jasmine and blue boxthorn. See *Caulis*.

Flake-white. Oxide of bismuth.

FLA'MMULA. (Dim. of *flamma*, a fire: named from the burning pungency of its taste.) See *Ranunculus flammula*.

FLAMMULA JOVIS. See *Clematis recta*.

FLATULENT. Windy.

FLAX. See *Linum*.

Flax-leaved daphne. See *Daphne gnidium*.

Flax, purging. See *Linum catharticum*.

Flax, spurge. See *Daphne gnidium*.

FLEA-WORT. See *Plantago psyllium*.

FLE'MEN. (From *flecto*, to incline downwards.) *Flegma*. A tumour about the ankles.

FLERE'SIN. Gout.

FLESH. 1. The muscles of animals.

2. A vulgar term for all the soft parts of an animal.

3. It is also applied to leaves, fruit, &c. which have the appearance or consistence of flesh.

FLE'XOR. The name of several muscles, the office of which is to bend parts into which they are inserted.

FLEXOR ACCESSORIUS DIGITORUM PEDIS. See *Flexor longus digitorum pedis*.

FLEXOR BREVIS DIGITORUM PEDIS, PERFORATUS, SUBLIMIS. A flexor muscle of the toes, situated on the foot. *Flexor brevis digitorum pedis, perforatus* of Albinus. *Flexor brevis* of Douglas. *Flexor digitorum brevis, sive perforatus pedis* of Winslow. *Perforatus, seu flexor secundi internodii digitorum pedis* of Cowper; and *Calcano sus-phalangettien commun* of Dumas. It arises by a narrow, tendinous, and fleshy beginning, from the inferior protuberance of the os calcis. It likewise derives many of its fleshy fibres from the adjacent aponeurosis, and soon forms a thick belly, which divides into four portions. Each of these portions terminates in a flat tendon, the fibres of which decussate, to afford a passage to a tendon of the long flexor, and afterwards re-uniting, are inserted into the second phalanx of each of the four lesser toes. This muscle serves to bend the second joint of the toes.

FLEXOR BREVIS MINIMI DIGITI PEDIS. *Parathenar minor* of Winslow. This little muscle is situated along the inferior surface and outer edge of the metatarsal bone of the little toe. It arises tendinous from the basis of that bone, and from the ligaments that connect it to the os cuboides. It soon becomes fleshy, and adheres almost the whole length of the metatarsal bone, at the anterior extremity of which it forms a small tendon, that is inserted into the root of the first joint of the little toe. Its use is to bend the little toe.

FLEXOR BREVIS POLLICIS MANUS. *Flexor secundi internodii* of Douglas. *Thenar* of Winslow. *Flexor primi et secundi ossis pollicis* of Cowper; and *Carpophalangein du pouce* of Dumas. This muscle is divided into two portions by the tendon of the flexor longus pollicis. The outermost portion arises tendinous from the anterior part of the os trapezoides and internal annular ligament. The second, or innermost, and thickest portion, arises from the same bone, and likewise from the os magnum, and os cuneiforme. Both these portions are inserted tendinous into these samoid bones of the thumb. The use of this muscle is to bend the second joint of the thumb.

FLEXOR BREVIS POLLICIS PEDIS. A muscle of the great toe, that bends the first joint of that part. *Flexor brevis* of Douglas. *Flexor brevis pollicis* of Cowper; and *Tarsophalangien du pouce* of Dumas. It is situated upon the metatarsal bone of the great toe, arises tendinous from the under and anterior part of the os calcis, and from the under part of the os cuneiforme externum. It soon becomes fleshy and divisible into two portions, which do not separate from each other till they have reached the anterior extremity of the metatarsal bone of the great toe, where they become tendinous, and then the innermost portion unites with the tendon of the abductor, and the outermost with that of the abductor pollicis. They adhere to the external os sesamoideum, and are finally inserted into the root of the first joint of the great toe. These two portions, by their separation, form a groove, in which passes the tendon of the flexor longus pollicis.

FLEXOR CARPI RADIALIS. A long thin muscle, situated obliquely at the inner and anterior part of the fore-arm, between the palmaris longus and the pronator teres. *Radialis internus* of Albinus and Winslow; and *Epitrochlo metacarpien* of Dumas. It arises tendinous from the inner condyle of the os humeri, and, by many fleshy fibres, from the adjacent tendinous fascia. It descends along the inferior edge of the pronator teres, and terminates in a long, flat and thin tendon, which afterwards becomes narrower and thicker, and, after passing under the internal annular ligament, in a groove distinct from the other tendons of the wrist, it spreads wider again, and is inserted into the fore and upper part of the metacarpal bone that sustains the fore-finger. It serves to bend the hand, and its oblique direction may likewise enable it to assist in its pronation.

FLEXOR CARPI ULNARIS. *Ulnaris inturnus* of Winslow and Albinus. *Epitrochli cubito carpien* of Dumas. A muscle situated on the cubit or fore-arm, that assists in bending the arm. It arises tendinous from the inner condyle of the os humeri, and, by a small fleshy origin, from the anterior edge of the olecranon. Between these two portions, we find the ulnar nerve passing to the fore-arm. Some of its fibres arise likewise from the tendinous fascia that covers the muscles of the fore-arm. In its descent, it soon becomes tendinous, but its fleshy fibres do not entirely disappear till it has reached the lower extremity of the ulna, where its tendon spreads a little, and after sending off a few fibres to the external and internal and annular ligaments, is inserted into the os pisiforme.

FLEXOR LONGUS DIGITORUM PEDIS PROFUNDUS PERFORANS. A flexor muscle of the toes, situated along the posterior part and inner side of the leg. *Perforans seu flexor profundus* of Douglas. *Flexor digitorum longus, sive perforans pedis*, and *perforans seu flexor tertii internodii digitorum pedis* of Cowper: and *Tibio phalangetien* of Dumas. It arises fleshy from the back part of the tibia, and, after running down to the internal ankle, its tendon passes under a kind of annular ligament, and then through a sinuosity at the inside of the os calcis. Soon after this it receives a small tendon from the flexor longus pollicis pedis, and about the middle of the foot it divides into four tendons, which pass through the slits of the flexor brevis digitorum pedis, and are inserted into the upper part of the last bone of all the lesser toes. About the middle of the foot, this muscle unites with a fleshy portion, which, from the name of its first describer, has been usually called *massa carnea Jacobi Sylvii*; it is also termed *Flexor accessorius digitorum pedis.* This appendage arises by a thin fleshy origin, from most part of the sinuosity of the os calcis, and likewise by a thin tendinous beginning from the anterior part of the external tubercle of that bone; it soon becomes all fleshy, and unites to the long flexor just before it divides into its four tendons. The use of this muscle is to bend the last joint of the toes.

FLEXOR LONGUS POLLICIS MANUS. *Flexor longus pollicis* of Albinus. *Flexor tertii internodii* of Douglas; *Flexor tertii internodii sive longissimus pollicis* of Cowper; and *radiophalangetien du pouce* of Dumas. A muscle of the thumb placed at the side of the flexor longus digitorum, profundus, perforans, and covered by the extensores carpi radiales. It arises fleshy from the anterior surface of the radius, immediately below the insertion of the biceps, and is continued down along the oblique ridge, which serves for the insertion of the supinator brevis, as far as the pronator quadratus. Some of its fibres spring likewise from the neighbouring edge of the interosseous ligament. Its tendon passes under the internal annular ligament of the wrist, and, after running along the inner surface of the first bone of the thumb, between the two portions of the flexor brevis pollicis, goes to be inserted into the last joint of the thumb, being bound down in its way by the ligamentous expansion that is spread over the second bone. In some subjects we find a tendinous portion arising from the inner condyle of the os humeri, and forming a fleshy slip that commonly terminates near the upper part of the origin of this muscle from the radius. The use of this muscle is to bend the last joint of the thumb.

FLEXOR LONGUS POLLICIS PEDIS. A muscle of the great toe, situated along the posterior part of the leg. It arises tendinous and fleshy a little below the head of the fibula, and its fibres continue to adhere to that bone almost to its extremity. A little above the heel it terminates in a round tendon, which, after passing in a groove formed at the posterior edge of the astragalus, and internal and lateral part of the os calcis, in which it is secured by an annular ligament, goes to be inserted into the last bone of the great toe, which it serves to bend.

FLEXOR OSSIS METACARPI POLLICIS. *Opponens pollicis* of Innus. *Opponent pollicis manus* of Albinus. *Flexor primi internodii* of Douglas. *Antithenar sive semi-interosseus pollicis* of Winslow; and *Carpo phalangien du pouce* of Dumas. A muscle of the thumb, situated under the abductor brevis pollicis, which it resembles in its shape. It arises tendinous and fleshy from the os scaphoides, and from the anterior and inner part of the internal annular ligament. It is inserted tendinous and fleshy into the under and anterior part of the first bone of the thumb. It serves to turn the first bone of the thumb upon its axis, and at the same time to bring it inwards opposite to the other fingers.

FLEXOR PARVUS MINIMI DIGITI. *Abductor minimi digiti, Hypothenar Riolani* of Douglas. *Hypothenar minimi digiti* of Winslow: and second *carpo-phalangien du petit doigt* of Dumas. A muscle of the little finger, situated along the inner surface of the metacarpal bone of the little finger. It arises tendinous and fleshy from the hook-like process of the unciform bone, and likewise from the anterior surface of the adjacent part of the annular ligament. It terminates in a flat tendon, which is connected with that of the abductor minimi digiti, and inserted into the inner and anterior part of the upper end of the first bone of the little finger. It serves to bend the little finger, and likewise to assist the abductor.

FLEXOR PROFUNDUS PERFORANS. *Profundus* of Albinus. *Perforans* of Douglas. *Perforans vulgo profundus* of Winslow; *Flexor tertii internodii digitorum manus, vel perforatus manus* of Cowper; and *Cubito phalangetien commun* of Dumas. A muscle of the fingers situated on the fore-arm, immediately under the *perforatus*, which it greatly resembles in its shape. It arises fleshy from the external side, and upper part of the ulna, for some way downwards, and from a large portion of the interosseus ligament. It splits into four tendons a little before it passes under the annular ligament of the wrist, and these pass through the slit in the tendons of the flexor sublimis, to be inserted into the fore and upper part of the third or last bone of all the four fingers, the joint of which they bend.

FLEXOR SUBLIMIS PERFORATUS. This muscle, which is the *perforatus* of Cowper, Douglas, and Winslow, is, by Albinus, and others, named *sublimis*. It has gotten the name of *perforatus*, from its tendons being perforated by those of another flexor muscle of the finger, called the *perforans*. They who give it the appellation of *sublimis*, consider its situation with respect to the latter, and which, instead of *perforans*, they name *profundus*. It is a long muscle, situated most commonly at the anterior and inner part of the fore-arm, between the palmaris longus and the flexor carpi ulnaris; but, in some subjects, we find it placed under the former of these muscles, between the flexor carpi ulnaris and the flexor carpi radialis. It arises, tendinous and fleshy, from the inner condyle of the os humeri, from the inner edge of the coronoid process of the ulna, and from the upper and fore part of the radius, down to near the insertion of the pronator teres. A little below the middle of the fore-arm, its fleshy belly divides into four portions, which degenerate into as many round tendons, that pass all together under the internal annular ligament of the wrist, after which they separate from each other, become thinner and flatter, and running along the palm of the hand, under the aponeurosis palmaris, are inserted into the upper part of the second bone of each finger. Previous to this insertion, however, the fibres of each tendon decussate near the extremity of the first bone, so as to afford a passage to a tendon of the perforans. Of these four tendons, that of the middle finger is the largest, that of the fore-finger the next in size, and that of the little finger the smallest. The use of this muscle is to bend the second joint of the fingers.

Flexor tertii internodii. See *Flexor longus pollicis manus.*

FLEXUOSUS. Flexuous; full of turnings or windings. A stem is so named which is zigzag, forming angles alternately from right to left, and from left to right; as in *Smilax aspera.*

FLINT. A hard stone, found in beds of chalk, and in primitive, transition, secondary, and alluvial mountains. Its constituents are silica, lime, alumina, and oxide of iron.

FLINTY SLATE. Busanite. A mineral, of which there are two kinds.

1. *Common flinty slate,* of an ash grey colour, with other colours, in flamed, striped, and spotted delineations. It is found in different parts of the great track of clay-slate and grey-wacke which extends from St. Abb's head to Portpatrick.

2. *Lydian-stone* of a greyish black and velvet black colour. It is found frequently along with common flinty-slate in beds of clay-slate. It occurs in Bohemia and the Pentland hills, near Edinburgh. It is sometimes used as a touchstone for ascertaining the purity of gold and silver.

FLOATSTONE. The spongiform quartz of Jameson.

FLOCCILATION. (*Floccilatio; from floccus,* the nap of clothes.) Picking the bed-clothes. A symptom of great danger in acute diseases.

FLORAL. (*Foralis;* from *flos,* a flower.) Belonging to a flower; as floral leaf. See *Bractea.*

Flores benzoes. See *Benzoic acid.*

Flores martiales. See *Ferrum ammoniatum.*

Flores salis ammoniaci. See *Ammoniæ subcarbonas.*

Flores sulphuris. See *Sulphur.*

Flores sulphuris loti. See *Sulphur lotum.*

FLORESCENTIA. (From *floresco,* to flourish or bloom.) The act of flowering, which Linnæus compares to the act of generation in animals.

FLORET. A little flower.

FLOS. (*Flos, ris.* f.; a flower.) I. A flower. That part of a plant, for the most part beautifully coloured, and protecting the internal organs.

Every flower has parts, which are

1. *Essential,* constituting properly the flower; as the pistil, stamen, aud receptacle.

2. *Less essential,* without which the flower is in some instances formed; as the *calyx, corolla,* and *pedunculus.*

3. *Accidental,* noticed in a few only; as the *bractea* and *nectarium.*

A flower is said to be

1. *Complete,* when furnished with calyx and corolla; as *Nicotiana tabacum.*

2. *Incomplete,* when the calyx or corolla is wanting.

3. *Naked,* devoid of the calyx; as in *Lilium candidum,* and *Tulipa gesneriana.*

4. *Apetaloid,* without the corolla; as in *Galenia Africana,* and *Saururus cernuus.*

When the stamens and pistils are both, as usual, in one flower, that flower is called *perfect,* or united; when they are situated in different flowers of the same species, they are called *separated flowers;* that which has the stamens being named the *barren* flower, as producing no fruit in itself, and that with the pistils the *fertile* one, as bearing the seed.

The flower contains the internal or genital parts of a plant:

1. The *stamen* or male genital organ.

2. The *pistillum* or female genital organ.

From their diversity, flowers are called,

1. *Male,* which have the stamina only.

2. *Female,* in which are the pistils only.

3. *Hermaphrodite,* which contain both stamens and pistils.

4. *Neuter,* naturally deficient of stamens and pistils; as the marginal flowers of the *Centaurea cyanus,* and *Jacobea.*

5. *Castrate,* when the anthers or the pistils are naturally wanting. The pistils, for example, are wanting in the *Calendula officinalis,* and in the *Viola mirabilis* there are no anthers.

6. *Abortive,* the fecundated germens of which wither before the maturity of the fruit; as happens to the florets in the radius of the *Helianthus annuus.*

7. *Monstrous,* when the internal organs become petals, as is the case with full or double flowers.

Besides these distinctions Linnæus's favourite division is into,

1. *Aggregate.*
2. *Compound.*
3. *Amentaceous.*
4. *Glumose,* or chaffy, peculiar to the grasses.
5. The *sheathed flower,* the common receptacle of which springs from a sheath; as in *Arum.*
6. The *umbellate.*
7. The *cymose.* See also *Inflorescence.*

II. A term used by former chemists to whatever had a flower-like appearance, especially if obtained by sublimation, as flowers of sulphur, benjamin, zinc, &c.

Flos ferri. A radiated variety of carbonate of lime.

FLOSCULUS. A little flower. A term applied in botany to the small and numerous florets of a compound flower, which are all sessile on a common undivided receptacle, and enclosed in one contiguous calyx, or perianth.

FLOUR. The powder of the gramineous seeds.

FLOWER. See *Flos.*

FLOWER-DE-LUCE. See *Iris germanica.*

Flowers of benjamin. See *Benzoic acid.*

FLOYER, Sir John, was born at Hinters, in Staffordshire, about the year 1649, and graduated at Oxford. He then settled at Litchfield, where his attention and skill procured him extensive reputation, insomuch that he was honoured with knighthood, as a reward for his talents. He strongly advocated the use of cold bathing, particularly in chronic rheumatism, and nervous disorders: and he ascribed the increasing prevalence of consumption to the discontinuance of the practice of baptizing children by immersion. He published several works on this and other subjects; particularly an excellent treatise on the Asthma, under which he himself laboured from the time of puberty, notwithstanding which he lived to be an old man. He is said to have been one of the first who reckoned the number of pulsations by a time-piece.

FLUATE. *Fluas.* A compound of the fluoric acid with salifiable bases: thus, fluate of lime, &c.

FLUCTUA'TION. *Fluctuatio.* A term used by surgeons, to express the undulation of a fluid; thus when pus is formed in an abscess, or when water accumulates in the abdomen, if the abscess or abdomen be lightly pressed with the fingers, the motion of fluctuation may be distinctly felt.

FLUELLIN. See *Antirrhinum elatine.*

FLUID. *Fluidus.* A fluid is that, the particles of which so little attract each other, that when poured out, it drops *guttatim*, and adapts itself in every respect to the form of the vessel containing it.

The fluids of animal bodies, and particularly those of the human body, are something very considerable in proportion to the solids; the ratio in the adult being as nine to one. Chaussier put a dead body of 120 pounds into an oven, and found it, after many days' successive desiccation, reduced to 12 pounds. Bodies found, after being buried for a long time in the burning sands of the Arabian deserts, present an extraordinary diminution of weight.

The animal fluids are sometimes contained in vessels, wherein they move with more or less rapidity; sometimes in little areolæ or spaces, where they seem to be kept in reserve; and at other times they are placed in the great cavities where they make only a temporary stay of longer or shorter duration.

The fluids of the human body are,

1. The blood.
2. The lymph.
3. The perspiratory or perspirable fluids, which comprise the liquids of cutaneous transpiration: the transpiration or exhalation of mucous membranes, as also of the synovial, serous, and cellular; of the adipose cells, the medullary membranes, the thyroid and thymus glands, &c.
4. The follicular fluid; the sebaceous secretion of the skin, the cerumen, the ropy matter from the eyelids, the mucus from the glands and follicles of that name from the tonsils, the cardiac glands, the prostate, the vicinity of the anus, and some other parts.
5. The glandular fluids; the tears, the saliva, the pancreatic fluid, the bile, the urine, the secretion from Cowper's glands, the semen, the milk, the liquid contained in the supra-renal capsules, that of the testicles, and of the mammæ of new-born infants.
6. The chyme and the chyle.

The properties of fluids, both chemical and physical, are exceedingly various. Many have some analogy to each other under these two relations; but none exhibit a perfect resemblance. The writers of all ages have attached a considerable degree of importance to their methodical arrangement; and according to the doctrine then flourishing in the schools, they have created different systems of classification. Thus, the ancients, who attributed much importance to the four elements, said that there were four principal humours, the blood, the lymph, or *pituita*, the yellow bile, the black bile, or *atra bilis;* and these four humours corresponded to the four elements, to the four seasons of the year, to the four divisions of the day, and to the four temperaments. Afterwards, at different periods, other divisions have been substituted to this classification of the ancients. Thus, some have made three classes of liquids:—1. the chyme and chyle; 2. the blood; 3. the humours emanating from the blood. Some authors have been content with forming two classes:—1. *primary*, alimentary, or useless fluids; 2. *secondary*, or useful. Consequently, they distinguished them into—

1. *Recrementitious*, or humours destined from their formation to the nourishment of the body.
2. *Excrementitious*, or fluids destined to be thrown off from the system;
3. Humours, which at times participate in the characters of the two former classes, and are therefore named *excremento-recrementitious.*

In later times, chemists have endeavoured to class the humours according to their intimate or component nature, and thus they have established albuminous, fibrinous, saponaceous, watery, &c. fluids.

FLUOBORATE. A compound of the fluoboric acid with a salifiable basis.

FLUOBORIC ACID. *Acidum fluoboricum.* Probably a compound of fluorine with boron. It is a gaseous acid, and may be obtained by heating in a glass retort twelve parts of sulphuric acid with a mixture of one part of fused boracic acid, and two of fluor-spar, reduced to a very fine powder. It must be received over mercury. It combines with salifiable bases, and forms salts called *fluoborites.*

FLU'OR. Octohedral fluor of Jameson. It is divided into three subspecies, compact fluor, foliated fluor, and earthy fluor. This genus of mineral abounds in nature, formed by the combination of the fluoric acid with lime. It is called spar, because it has the sparry form and fracture: fluor, because it melts very readily; and vitreous, because it has the appearance of glass, and may be fused into glass of no contemptible appearance.

Fluor albus. See *Leucorrhœa.*

FLUO'RIC ACID. (*Acidum fluoricum*, because obtained from the fluor-spar.) Hydrofluoric acid.

"The fusible spar which is generally distinguished by the name of Derbyshire spar, consists of calcareous earth in combination with this acid. If the pure fluor or spar, be placed in a retort of lead or silver, with a receiver of the same metal adapted, and its weight of sulphuric acid be then poured upon it, the fluoric acid will be disengaged by the application of a moderate heat. This acid gas readily combines with water; for which purpose it is necessary that the receiver should previously be half filled with that fluid.

If the receiver be cooled with ice, and no water put in it, then the condensed acid is an intensely active liquid. It has the appearance of sulphuric acid, but is much more volatile, and sends off white fumes when exposed to air. Its specific gravity is only 1.0609. It must be examined with great caution, for when applied to the skin it instantly disorganizes it, and produces very painful wounds. When potassium is introduced into it, it acts with intense energy, and produces hydrogen gas and a neutral salt; when lime is made to act upon it, there is a violent heat excited, water is formed, and the same substance as fluor-spar is produced. With water in a certain proportion, its density increases to 1.25. When it is dropped into water, a hissing noise is produced, with much heat, and an acid fluid not disagreeable to the taste is formed if the water be in sufficient quantity. It instantly corrodes and dissolves glass.

It appears extremely probable, from all the facts known respecting the fluoric combinations, that fluor-spar contains a peculiar acid matter; and that this acid matter is united to lime in the spar, seems evident from the circumstance that gypsum or sulphate of lime is the residuum of the distillation of fluor-spar and sulphuric acid. The results of experiments on fluor-spar have been differently stated by chemists.

Some have considered fluoric acid as a compound of fluorine with hydrogen, but it seems on the whole to be the *analogy* of chlorine. But the analogy is incomplete. Certainly it is consonant to the true logic of chemical science to regard chlorine as a simple body, since every attempt to resolve it into simpler forms of matter has failed. But fluorine has not been exhibited in an insulated state like chlorine; and here therefore the analogy does not hold.

The marvellous activity of fluoric acid may be inferred from the following remarks of Sir H. Davy, from which also may be estimated in some measure the prodigious difficulty attending refined investigations on this extraordinary substance.

'I undertook the experiment of electrising pure liquid fluoric acid with considerable interest, as it seemed to offer the most probable method of ascertaining its real nature; but considerable difficulties occurred in executing the process. The liquid fluoric acid immediately destroys glass, and all animal and vegetable substances; it acts on all bodies containing metallic oxides; and I know of no substances which are not rapidly dissolved or decomposed by it, except metals, charcoal, phosphorus, sulphur, and certain combinations of chlorine. I attempted to make tubes of sulphur, of muriates of lead, and of copper containing metallic wires, by which it might be electrised, but without success. I succeeded, however, in boring a piece of horn silver in such a manner that I was able to cement a platina wire into it by means of a spirit lamp; and by inverting this in a tray of platina, filled with liquid fluoric acid, I contrived to submit the fluid to the agency of electricity in such a manner, that, in successive experiments, it was possible to collect any elastic fluid that might be produced. Operating in this way with a very weak voltaic power, and keeping the apparatus cool by a freezing mixture, I ascertained that the platina wire at the positive pole rapidly corroded, and became covered with a chocolate powder; gaseous matter separated at the negative pole, which I could never obtain in sufficient quantities to analyse with accuracy, but it inflamed like hydrogen. No other inflammable matter was produced when the acid was pure.'

If instead of being distilled in metallic vessels, the mixture of fluor-spar and oil of vitriol be distilled in glass vessels, little of the corrosive liquid will be obtained; but the glass will be acted upon, and a peculiar gaseous substance will be produced, which must be collected over mercury. The best mode of procuring this gaseous body is to mix the fluor-spar with pounded glass or quartz; and in this case the glass retort may be preserved from corrosion, and the gas obtained in greater quantities. This gas, which is called *silicated fluoric gas*, is possessed of very extraordinary properties.

It is very heavy; about 48 times denser than hydrogen. When brought into contact with water, it instantly deposits a white gelatinous substance, which is hydrate of silica; it produces white fumes when suffered to pass into the atmosphere. It is not affected by any of the common combustible bodies; but when potassium is strongly heated in it, it takes fire and burns with a deep red light; the gas is absorbed, and a fawn-coloured substance is formed, which yields alkali to water with slight effervescence, and contains a combustible body. The washings afford potassa, and a salt, from which the strong acid fluid previously described, may be separated by sulphuric acid.

If, instead of glass or silica, the fluor-spar be mixed with dry vitreous boracic acid, and distilled in a glass vessel with sulphuric acid, the proportions being one part boracic acid, two fluor-spar, and twelve oil of vitriol, the gaseous substance formed is of a different kind, and is called the *fluoboric gas*. It is colourless; its smell is pungent, and resembles that of muriatic acid; it cannot be breathed without suffocation; it extinguishes combustion; and reddens strongly the tincture of turnsole. It has no manner of action on glass, but a very powerful one on vegetable and animal matter. It attacks them with as much force as concentrated sulphuric acid, and appears to operate on these bodies by the production of water; for while it carbonises them, or evolves carbon, they may be touched without any risk of burning. Exposed to a high temperature, it is not decomposed; it is condensed by cold without changing its form. When it is put in contact with oxygen, or air, either at a high or low temperature, it experiences no change, except seizing, at ordinary temperatures, the moisture which these gases contain. It becomes in consequence a liquid which emits extremely dense vapours. It operates in the same way with all the gases which contain hygrometric water. However little they may contain, it occasions in them very perceptible vapours. It may hence be employed with advantage to show whether or not a gas contains moisture.

No combustible body, simple or compound, attacks fluoboric gas, if we except the alkaline metals. Potassium and sodium, with the aid of heat, burn in this gas, almost as brilliantly as in oxygen. Boron, and fluate of potassa are the products of this decomposition. It might hence be inferred, that the metal seizes the oxygen of the boracic acid, sets the boron at liberty, and is itself oxidised and combined with the fluoric acid. According to Sir H. Davy's views, the fluoboric gas, being a compound of fluorine and boron, the potassium unites to the former, giving rise to the fluoride of potassium, while the boron remains disengaged.

Fluoboric gas is very soluble in water. Dr. John Davy says, water can combine with 700 times its own volume, or twice its weight, at the ordinary temperature and pressure of the air. The liquid has a specific gravity of 1.770. If a bottle containing this gas be uncorked under water, the liquid will rush in and fill it with explosive violence. Water saturated with this gas is limpid, fuming, and very caustic. By heat about one-fifth of the absorbed gas may be expelled; but it is impossible to abstract more. It then resembles concentrated sulphuric acid, and boils at a temperature considerably above 212°. It afterwards condenses altogether, in *striæ*, although it contains still a very large quantity of gas. It unites with the bases forming salts, called fluoborates, none of which has been applied to any use.

The 2d part of the Phil. Transactions for 1812, contains an excellent paper by Dr. John Davy on fluosilicic and fluoboric gases, and the combinations of the latter with ammoniacal gas. When united in equal volumes, a pulverulent salt is formed; a second volume of ammonia, however, gives a liquid compound; and a third of ammonia, which is the limit of combination, affords still a liquid; both of them curious on many accounts. 'They are,' says he, 'the first salts that have been observed liquid at the common temperature of the atmosphere. And they are additional facts in support of the doctrine of definite proportions, and of the relation of volumes.' The fluosilicic acid also unites to bases forming fluosilicates.

From the remarkable property fluoric acid possesses of corroding glass, it has been employed for etching on it, both in the gaseous state, and combined with water; and an ingenious apparatus for this purpose is given by Mr. Richard Knight, in the Philosophical Magazine, vol. xvii. p. 357.

Of the combinations of this acid with most of the bases, little is known.

Beside the fluor spar and cryolite, in which it is abundant, fluoric acid has been detected in the topaz; in wavelite, in which, however, it is not rendered sensible by sulphuric acid; and in fossil teeth and fossil ivory, though it is not found in either of these in their natural state."—*Ure's Chem. Dict.*

Fluoric acid, silicated. See *Fluoric acid.*

FLUORIDE. A combination of fluorine with a salifiable basis.

FLUORINE. The imaginary radical of fluoric acid.

FLUOSILICIC ACID. See *Fluoric acid.*

FLUX. 1. This word is often employed for *dysenteria.*

2. A general term made use of to denote any substance or mixture added to assist the fusion of metals.

FLUXION. *Fluxio.* A term mostly applied by chemists, to signify the change of metals, or other bodies from the solid into the fluid state, by the application of heat. See *Fusion.*

FLY. *Musca.*

Fly, Spanish. See *Cantharis.*

FO'CILE. The ulna and the radius are occasionally denominated by the barbarous appellations of *focile majus* and *minus;* the tibia and fibula in the leg are also so called.

Fo'cus. A lobe of the liver.

Fodi'na. (From *fodio*, to dig.) A quarry. The labyrinth of the ear.

Fœnicula'tum lignum. A name for sassafras.

FŒNI'CULUM. (*Quasi fœnum oculorum,* the hay or herb good for the sight; so called because it is thought good for the eyes.) Fennel. See *Anethum.*

Fœniculum alpinum. The herb spignel. See *Æthusa meum.*

Fœniculum annuum. Royal cummin.

Fœniculum aquaticum. See *Phellandrium aquaticum.*

Fœniculum dulce. See *Anethum fœniculum.*

Fœniculum germanicum. See *Anethum fœniculum.*

Fœniculum marinum. Samphire.

Fœniculum orientale. See *Cuminum.*

Fœniculum porcinum. See *Peucedanum officinale.*

Fœniculum sinense. Aniseed.

Fœniculum sylvestre. Bastard spignel. See *Seseli montanum* of Linnæus.

Fœniculum tortuosum. French hart-wort. See *Seseli tortuosum.*

Fœniculum vulgare. See *Anethum fœniculum.*

FŒ'NUM. (*Fœnum, i.* n. hay.) Hay.

Fœnum camelorum. See *Juncus odoratus.*

Fœnum græcum. See *Trigonella fœnum græcum.*

Fœnum sylvestre. Wild fenugreek.

FOËSIUS, Anutius, was born at Mentz, in 1528, and received his education at Paris, where he imbibed a strong predilection for the Greek language, and particularly the works of Hippocrates. Returning to his native place about the age of 28, his talents soon procured him such extensive reputation, that several princes endeavoured to allure him to their respective courts, but without success. The practice of his profession, instead of weakening his attachment to Hippocrates, only stimulated him to a more profound study of his writings; where he found the most correct delineations of diseases, and the most important observations concerning them, made about two thousand years before. He first published an excellent Latin translation and commentary on his second book of Epidemics; then an explanation of the terms used by him, under the title of "Œconomia Hippocratis;" and, lastly, at the solicitation of the chief physicians of Europe, he undertook a complete correct edition of his works, with an interpretation and notes, which he accomplished in six years, in such a manner as to rank him among the ablest interpreters of the ancients. He was also author of a Pharmacopœia for his native city; and died in 1595.

Fœta'bulum. (From *fœteo*, to become putrid.) 1. An encysted abscess.

2. A foul ulcer.

FŒ'TUS. (From *feo*, to bring forth, according to Vossius.) *Epicyema; Epigonion.* The child enclosed in the uterus of its mother, is called a fœtus from the fifth month after pregnancy until the time of its birth. See *Ovum.*

Foliata terra. 1. Sulphur.

2. An old name of the acetate of potassa.

FOLIATIO. (From *folium*, a leaf.) The manner in which leaves are folded up in their buds. See *Vernatio.*

FOLIA'TUS. (From its resemblance to *folium*, a leaf.) Foliate, leafy.

FOLICULUS. (Diminutive of *follis*, a leather bag.) A small follicle.

FOLIOLUM. A leaflet or little leaf.

FO'LIUM. (*Folium, i.* n.; from φυλλον, the leaf of a tree.) See *Leaf.*

Folium orientale. See *Cassia senna.*

FOLLICLE. (*Folliculus;* diminutive of *follis*, a bag.) A small bag; applied to glands. See *Folliculose.*

FOLLICULOSE. (*Folliculosus; from folliculus*, a little bag.) A term applied to a simple gland or follicle. One of the most simple species of gland, consisting merely of a hollow vascular membrane or follicle, and an excretory duct; such are the muciparous glands, the sebaceous, &c.

FOLLI'CULUS. (Diminutive of *follis*, a bag.) 1. A little bag. See *Folliculose.*

2. In botany, a follicle is a one-valved pericarp, or seed-vessel. It has one cell and bursts lengthwise, and bears the seeds on or near its edges, or on a receptacle parallel therewith.

From the adhesion of the seeds it is distinguished into,

1. Follicle, *with a partition*, when the seeds adhere to an intermediate dissepiment.

2. Follicle, *without a partition*, when the seeds adhere to the internal sides only.

From the number of seeds,

1. *Monosperm follicle;* as in *Orontium.*
2. *Polysperm;* as in *Asclepias syriaca.*

From the direction into,

1. *Erect;* as in *Vinca* and *Nerium.*
2. *Reflected;* as in *Plumeria.*
3. *Horizontal;* as in *Cameraria.*

Folliculus fellis. The gall-bladder.

FOMENTA'TION. *Fomentatio.* A sort of partial bathing, by applying hot flannels to any part, dipped in medicated decoctions, whereby steams are communicated to the parts, their vessels are relaxed, and their morbid action sometimes removed.

Fomes ventriculi. Hypochondriacism.

FO'MITES. A term mostly applied to substances imbued with contagion.

FONS. A fountain.

Fons pulsatilis. See *Fontanella.*

FONTANE'LLA. (Diminutive of *fons*, a fountain.) *Fons pulsatilis*. The parietal bones and the frontal do not coalesce until the third year after birth, so that, before this period, there is an obvious interstice, commonly called *mould*, and scientifically the *fontanel*, or *fons pulsatilis*. There is also a lesser space, occasionally, between the occipital and parietal bones, termed the *posterior fontanel*. These spaces between the bones are filled up by the dura mater, pericranium, and external integuments, so that, during birth, the size of the head may be lessened; for, at that time, the bones of the head, upon the superior part, are not only pressed nearer to each other, but they frequently lap over one another, in order to diminish the size during the passage of the head through the pelvis.

FONTI'CULUS. (Diminutive of *fons*.) An issue. An artificial ulcer formed in any part, and kept discharging by introducing daily a pea, covered with any digestive ointment.

FORA'MEN. (From *foro*, to pierce.) A little opening.

Foramen cœcum. 1. A single opening in the basis of the cranium between the ethmoid and the frontal bone, that gives exit to a small vein.

2. The name of a hole in the middle of the tongue.

Foramen lacerum in basi cranii. A foramina in the basis of the cranium, through which the internal jugular vein, and the eighth pair and accessary nerves pass.

Foramen lacerum orbitale superius. A large opening between the greater and lesser wing of the sphenoid bone on each side, through which the third, fourth, first branch of the fifth, and the sixth pair of nerves, and the ophthalmic artery pass.

Foramen opticum. The hole transmitting the optic nerve.

Foramen ovale. The opening between the two auricles of the heart of the fœtus. See also *Innominatum os.*

Foramen of Winslow. An opening in the omentum. See *Omentum.*

Forami'nulum os. The ethmoid bone.

Force vital. See *Vis vitæ.*

FO'RCEPS. (*Forceps*, *cipis*. f.; *quasi ferriceps*, as being the iron with which we seize any thing hot, from *ferrum*, iron, and *capio*, to take.) Pincers. A surgical instrument with which extraneous bodies or other substances are extracted. Also an instrument occasionally used by men midwives to bring the head of the fœtus through the pelvis.

FORDYCE, George, was born at Aberdeen, in 1736, after the death of his father, and his mother having married again, he was sent to Fouran when about two years old, where he received his school education; and thence returned to Aberdeen, where he was made master of arts, when only fourteen. Having evinced an inclination to medicine, he was soon after sent to his uncle, Dr. John Fordyce, who practised at Uppingham, with whom he remained several years. He then studied at Edinburgh, where he graduated in 1758, having defended a thesis on catarrh: after which he went to Leyden, principally to improve himself in anatomy under Albinus. The following year he settled in London, and began to give lectures on chemistry; and in 1764, he undertook also to teach the practice of physic, and the materia medica: these subjects occupied him nearly three hours every morning, except on Sunday, for about thirty years successively. In 1770, he was chosen physician to St. Thomas's hospital, and six years after a Fellow of the Royal Society: also in 1787 he was admitted a Fellow of the College of Physicians; having been a licentiate for twenty-two years before. In 1793 he assisted in forming a small society for the improvement of Medical and Chirurgical Knowledge, which has since published three volumes of their Transactions. He died in 1802. The countenance of Dr. Fordyce was by no means expressive of his powers of mind: he was rather negligent of his dress, and not sufficiently pleasing in his manners, to enable him to get into very extensive practice: besides he was too fond of the pleasures of society, to which he often sacrificed the hours that should have been dedicated to sleep. The vigour of his constitution long resisted these irregularities; but at length they brought on the gout, which was followed by dropsy, and this terminated his existence. He possessed a remarkably strong memory, which enabled him to lecture without any notes, and to compose his works for publication without referring to authors, which he had before read; and his having relied too much on this faculty may help to explain the want of method and elegance, and the many inaccuracies, which appear in his writings. He was author of several publications on Medical and Philosophical subjects; many of which are to be found in the transactions of the societies to which he belonged. The most esteemed, and that on which he employed most labour, was a series of "Dissertations on Fever;" four of them appeared during his life, and another was left in manuscript, which has since been printed. His Treatise on Digestion, was read originally as the Gulstonian Lecture before the College of Physicians. He was the projector of the Experiments in heated rooms, of which Sir Charles Blagden gave an account.

FORDYCE, Sir William, was born at Aberdeen in 1724. At the age of eighteen, having acquired a competent knowledge of physic and surgery, he went into the army. The support of the friends, whom he there procured, together with his own merit, soon brought him into great practice, when he afterwards settled in London. The wealth, which he thus acquired, was liberally employed in acts of friendship, and in supporting useful projects; though he had some very severe losses. He wrote a Treatise on Fevers, and on the Ulcerated Sore Throat; on his entering into practice, he likewise published on the Venereal Disease. He died after a long illness in 1792.

FORENSIC. *Forensis*. Belonging to the forum, or courts of law: hence forensic medicine is that which is connected with a legal inquiry as to the cause of defect, disease, or death.

FORESKIN. See *Prepuce.*

FORESTUS, or Van Forest, Peter, was born at Alcmaer, in 1522. He was sent to Louvain to study the law, but soon showed a strong inclination to medicine. He therefore cultivated this science at different universities in Italy, and afterwards at Paris; but he graduated at Bologna. After being twelve years settled in his native town, he was invited to Delft, which was ravaged by a contagious epidemic; and being extremely successful in the treatment of this, he received a considerable pension, and was retained as the public physician for nearly thirty years. In 1575 he was prevailed upon to give the first lecture on Medicine at the opening of the University of Leyden. He spent the latter part of his life in his native city, where he died in 1597. He was a very diligent observer of diseases, and showed often great judgment in anticipating the result, or in treating them successfully. He published at different periods six volumes of Medical and Surgical Cases; to one of which was added a Dissertation, exposing the fallacy and absurdity of pretending to judge of every thing by the urine. Boerhaave has highly commended his writings which have been often reprinted.

FO'RMIATE. *Formias.* A compound produced by the union of the formic acid with a salifiable basis; thus, *fomiate of ammonia*, &c.

Formic acid. See *Formica rufa.*

FORMI'CA. (*Formica, æ.* f.; *quod ferat micas*, because of his diligence in collecting small particles of provision together.)

1. The name of a genus of insects. The ant or pismire. See *Formica rufa.*

2. The name of a black wart with a broad base, and cleft superficies, because the pain attending it resembles the biting of an ant.

3. A varicose tumour on the anus and glans penis.

Formica miliaris. Any herpetic eruption.

Formica rufa. The ant or pismire. This industrious little insect contains an acid juice, and gross oil, which were supposed to possess aphrodisiac virtues. The chrysalides of this animal are said to be diuretic and carminative, and by some recommended in the cure of dropsy.

The ant also furnishes an acid called the formic, which it has been long known to contain, and occasionally to emit. It may be obtained, either by simple distillation, or by infusion of them in boiling water, and subsequent distillation of as much of the water as can be brought over without burning the residue. After this it may be purified by repeated rectifications, or by boiling to separate the impurities; or after rectification it may be concentrated by frost.

This acid has a very sour taste, and continues liquid even at very low temperatures. Its specific gravity is 1.1168 at 68°, which is much denser than acetic acid ever is.

Dobereiner has recently succeeded in forming this acid artificially. When a mixture of tartaric acid, or of cream of tartar, black oxide of magnesia and water is heated, a tumultuous action ensues, carbonic acid is evolved, and a liquid acid distils over, which, on superficial examination, was mistaken for acetic acid, but which now proves to be formic acid. This acid, mixed with concentrated sulphuric acid, is at common temperatures converted into water and carbonic oxide; nitrate of silver or of mercury converts it, when gently heated, into carbonic acid, the oxides being at the same time reduced to the metallic state. With barytes, oxide of lead, and oxide of copper, it produces compounds, having all the properties of the genuine formiates of these metals. If a portion of sulphuric acid be employed in the above process, the tartaric acid is resolved entirely into carbonic acid, water, and formic acid; and the product of the latter is much increased. The best proportions are, two parts tartaric acid, five peroxide of manganese, and five sulphuric acid diluted with about twice its weight in water.

Fo'rmix. See *Herpes exedens.*

FO'RMULA. (Diminutive of *forma*, a form.) A little form of prescriptions, such as physicians direct in extemporaneous practice, in distinction from the greater forms in pharmacopœias, &c.

Fo'rnax. A furnace.

FORNICIFORMIS. Vaulted. Applied to the nectary of some plants; as the *Symphytum officinale*, &c. See *Nectarium.*

FO'RNIX. (*Fornix*, an arch or vault.) A part of the corpus callosum in the brain is so called, because, if viewed in a particular direction, it has some resemblance to the arch of an ancient vault. It is the medullary body, composed of two anterior and two posterior crura, situated at the bottom and inside of the lateral ventricle over the third ventricle, and below the septum lucidum.

FO'SSA. (From *fodio*, to dig.) *Fovea.* A little depression of sinus. The pudendum muliebre.

Fossa amyntæ. A double-headed roller for the face.

Fossa magna. 1. The great groove of the ear.

2. The pudendum muliebre.

Fossa navicularis. 1. The cavity at the bottom of the entrance of the pudendum muliebre.

2. The great groove of the ear.

Fossa ovalis. The depression in the right auricle of the human heart, which in the fœtus opened into the other auricle, forming the foramen ovale.

Fossa pituitaria. The depression in the sella turcica of the sphenoid bone.

FO'SSIL. (*Fossilis;* from *fodio*, to dig.) Any thing dug out of the earth.

Fossil copal. Highgate resin. A semi-transparent, brittle, resinous substance, of a yellowish-brown colour; found in the bed of blue clay at Highgate, near London.

Fo'ssilus. The bone of the leg.

FOTHERGILL, John, was born in Yorkshire, in 1712, of a respectable Quaker family. After passing through an apprenticeship to an apothecary, he went to Edinburgh, where he graduated at the age of twenty-four, taking for his inaugural thesis the use of emetics. He then studied for two years at St. Thomas's Hospital, and after an excursion to the continent, settled in London in 1740, and six years after became a licentiate. His practice was for some time chiefly gratuitous; but his "Account of the Putrid Sore Throat," published in 1748, brought him speedily into reputation. He was successively elected a Fellow of the College of Physicians at Edinburgh, of the Royal Society of London, and of some other societies abroad. His early partiality to botany induced him, as his practice increased, to purchase a large piece of ground for the cultivation of rare and valuable plants, in which he spared no expense; neither did he neglect other departments of natural history. He was also an active and liberal promoter of many successful schemes for the public benefit; and particularly in instituting the school at Ackworth in Yorkshire. He was of a rather delicate constitution, but a steady temperance preserved his health, till in 1778 he had an attack of a suppression of urine, occasioned by a disease of the prostate gland; which, returning two years after, soon put a period to his existence. He had a quick and comprehensive understanding: and his pleasing address procured him general confidence, which his discretion was not apt to forfeit afterwards. Besides the works already noticed, several papers of Dr. Fothergill were printed in the Philosophical Transactions, and in the Medical observations and Enquiries; he also sent several communications to the Gentleman's Magazine, and other periodical publications.

FO'TUS. (*Fotus ûs.* m.) See *Fomentation.*

FO'VEA. (From *fodio*, to dig.) 1. A little depression.

2. The pudendum muliebre.

3. A partial sweating-bath.

FOVEATUS. Having a little depression, or pit. Applied to the nectary of plants. See *Nectarium.*

FOX-GLOVE. See *Digitalis.*

Fox-glove, Eastern. See *Sesamum orientale.*

FRACASTORIUS, HIERONYMUS, was born at Verona, in 1483. He made a rapid progress in his studies, and attained early considerable excellence as a poet, philosopher, and astronomer. He was also much valued as a physician, particularly by the general of the Venetian army, whom he attended during several campaigns: but on his dying, in 1515, Fracastorius returned to his native place. He corresponded with most of the great men of his age, especially with Cardinal Bembo, to whom he dedicated his poem "Syphilis;" which was thought worthy of comparison with the Georgics of Virgil by some of the best judges. He died in 1553; and a statue was erected to him by the town of Verona. He published also on Contagious Diseases, and several other Medical and Philosophical Subjects.

FRA'CTURE. (*Fractura*; from *frango*, to break.) *Catagma; Clasis; Clasma; Agme.* A solution of a bone into two or more fragments. A *simple* fracture is when the bone only is divided. A *compound* fracture is a division of the bone, with a laceration of the integuments, the bone mostly protruding. A fracture is also termed transverse, oblique, &c. according to its direction.

FRÆ'NULUM. (Diminutive of *frænum*, a bridle.) The cutaneous fold under the apex of the tongue, that connects the tongue to the infralingual cavity. It is sometimes, in infancy, so short as to prevent the child from sucking, when it is necessary to cut it, in order to give more room for the motion of the tongue.

FRÆ'NUM. The membraneous fold which connects the prepuce to the inferior part of the glans penis.

FRA'GARIA. (From *fragro*, to smell sweet.) The strawberry. 1. The name of a genus of plants in the Linnæan system. Class, *Icosandria*; Order, *Polygynia.*

2. The pharmacopœial name of the strawberry. See *Fragaria vesca.*

FRAGARIA STERILIS. Barren strawberry. Astringent, seldom used.

FRAGARIA VESCA. The systematic name of the strawberry plant. *Fragaria.* The mature fruit of the *Fragaria, fragellis reptantibus* of Linnæus, was formerly recommended in gouty and calculous affections, in consequence, it would appear, of its efficacy in removing tartar from the teeth, which it is said to do very effectually.

FRAGILE VITREUM. An obsolete name for the fragilitas ossium.

FRAGILIS. Brittle.

FRAGI'LITAS. Brittleness.

FRAGILITAS OSSIUM. Brittleness of the bones.

FRA'GMEN. *Fragmentum.* A splinter of a bone.

FRA'GUM. (From *fragro*, to smell sweet.) The strawberry. See *Fragaria.*

FRAMBŒ'SIA. (From *framboise*, Fr. for a raspberry.) The yaws. A genus of disease, arranged by Cullen in the class *Cachexiæ*, and order *Impetigines.* It is somewhat similar in its nature to the lues venerea, and is endemial to the Antilles islands, as well as Africa. It appears with excrescences like mulberries growing out of the skin in various parts of the body, which discharge an ichorous fluid.

FRA'NGULA. (From *frango*, to break: so called because of the brittleness of its branches.) See *Rhamnus frangula.*

FRANKINCENSE. See *Juniperus lycia*, and *Pinus abies.*

FRAXINE'LLA. (From *fraxinus*, the ash: so called because its leaves resemble those of the ash.) See *Dictamnus albus.*

Fraxinella, white. See *Dictamnus albus.*

FRA'XINUS. (*A fragore*, from the noise its seeds make when shaken by the wind; or from φραξις, a hedge, because of its use in forming hedges.) The ash.

1. The name of a genus of plants in the Linnæan system. Class, *Polygamia;* Order, *Diœcia.*

2. The pharmacopœial name of the ash-tree. See *Fraxinus excelsior.*

FRAXINUS EXCELSIOR. The systematic name of the ash-tree. *Fraxinus.* Called also *brumelli* and *bumelia.* The bark of this tree, *Fraxinus—foliis serratis floribus apetalis* of Linnæus, when fresh, has a moderately strong bitterish taste. It possesses resolvent and diuretic qualities, and has been successfully exhibited in the cure of intermittents. The seeds are occasionally exhibited medicinally as diuretics, in the dose of a drachm. In warm climates, a sort of manna exudes from this species of fraxinus.

FRAXINUS ORNUS. The systematic name of the tree from which manna flows. This substance is also termed *Manna calabrina; Ros calabrinus; Acromeli; Alusar; Drysomeli.* That species which is of a rosy colour is called *nuba. Mel aërium*, from the supposition that it descended from heaven. Manna is the condensed juice of the flowering ash, or *Fraxinus ornus—foliis ovato oblongis serratis petiolatis, floribus corollatis*, Hort. Kew. which is a native of the southern parts of Europe, particularly Sicily and Calabria. Many other trees and shrubs have likewise been observed to emit a sweet juice, which concretes upon exposure to the air, and may be considered of the manna kind, especially the *Fraxinus rotundifolia* and *excelsior.* In Sicily these three species of fraxinus are regularly cultivated for the purpose of procuring manna, and with this view are planted on the declivity of a hill with an eastern aspect. After ten years' growth, the trees first begin to yield the manna, but they require to be much older before they afford it in any considerable quantity. Although the manna exudes spontaneously upon the trees, yet, in order to obtain it more copiously, incisions are made through the bark, by means of a sharp crooked instrument; and the season thought to be most favourable for instituting this process, is a little before the dog days commence, when the weather is dry and serene. Manna is generally distinguished into different kinds, viz. the manna in tear, the canulated and flaky manna, and the common brown or fat manna. All these varieties seem rather to depend upon their respective purity, and the manner in which they are obtained from the plant, than upon any essential difference of the drug. The best manna is in oblong pieces or flakes, moderately dry, friable, very light, of a whitish or pale yellow colour, and in some degree transparent: the inferior kinds are moist, unctuous, and brown. Manna is well known as a gentle purgative, so mild in its operation, that it may be given with safety to children and pregnant women, to the delicacy of whose frames and situations it is particularly adapted. It is esteemed a good and pleasant auxiliary to the purgative neutral salts. It sheathes acrimony, and is useful in coughs, disorders of the breast, and such as are attended with fever and inflammation, as in pleuritis, &c. It is particularly efficacious in bilious complaints, and helps the discharge of mineral waters, when they are not of themselves sufficiently active. It is apt, in large doses, to create flatulencies and gripes; both of which are prevented by a small addition of some warm carminatives. It purges in doses of from ℥j to ℥jj; but its purgative quality is much increased, and its flatulent effects prevented, by a small addition of cassia. The dose for children is from one scruple to three. It is best dissolved in whey.

FRAXINUS ROTUNDIFOLIA. The systematic name of a tree which affords manna. See *Fraxinus ornus.*

FREIND, JOHN, was born in 1675, at Croton, in Northamptonshire, of which his father was rector. After being educated at Westminster, he went to Oxford, where he distinguished himself greatly by his classical attainments. Having for some time studied medicine, he communicated to the Royal Society some singular cases: but a work, which he published in 1703, entitled "Emmenologia," explaining the phenomena of menstruation, both natural and morbid, on mechanical principles, first brought him into notice as a physiologist and physician. In the following year he was appointed professor of Chemistry at Oxford, but soon after went to Spain as physician to the English forces; and he took this opportunity of visiting Italy. On his return, in 1707, he was created Doctor by diploma, and published his Chemical Lectures in Latin. In 1712, he was chosen a Fellow of the Royal Society; but soon went abroad again with the troops into Flanders. On the conclusion of the peace in the following year he settled in London, and rose to high professional reputation. In 1716, he was received as Fellow of the College of Physicians, and published the first and third books of Hippocrates on Epidemics, with a Commentary on Fevers, in nine parts; a work of great erudition and judgment. Some of his opinions having been severely attacked, he was led to defend them in a letter to Dr. Mead, entitled "De purgantibus in secundo Variolarum confluentium Febre adhibendis," 1719. A few years after this he got into parliament, and having warmly sided with the opposition, he was, in common with several persons of consequence, imprisoned on suspicion of high treason: but the minister, Sir Robert Walpole, having fallen sick, Dr. Mead refused to attend him till his friend was liberated; when he made over to him 5000 guineas, which he had received from his patients during his confinement of a few months only. While in the Tower, Dr. Freind formed the plan of his great work, "The History of Physic from Galen to the beginning of the Sixteenth Century, chiefly with regard to Practice;" which came out in two volumes within three years after. This was intended as a continuation of Le Clerc, and met with a very favourable reception; indeed it still continues to be a standard book. On the accession of George II. he was appointed physician to the Queen; and having died in July 1728, his widow and son experienced the royal protection.

FRE'NA. The sockets of the teeth.

FRIGERA'NA. A putrid fever.

FRIGIDA'RIUM. (From *frigidus*, cold.) The cold bath.

FRINGE. See *Fimbria.*

Fringed leaf. See *Leaf.*

FRONS. (*Frons, tis.* f. or m.) 1. The forehead. The part between the eyebrows and the hairy scalp.

2. (*Frons, dis,* f.) The frond, or leaf; a tree; now used by botanists to the cryptogamious plants only.

FRONTAL. (*Frontalis;* from *frons,* the forehead.) Belonging to the forehead.

Frontal-bone. See *Frontis os.*

Frontal sinus. See *Frontis os.*

FRONTA'LIS. See *Occipitio frontalis.*

FRONTALIS VERUS. See *Corrugator supercilii.*

FRO'NTIS OS. The frontal bone. *Os coronale; Os inverecundum; Metopon.* The external surface of this bone is smooth at its upper convex part, but below several cavities and processes are observed. At each angle of the orbits the bone jets out to from two internal and two external processes; and the ridge under the eyebrow on each side is called the superciliary process; from which the orbitar processes extend backwards, forming the upper part of the orbits; and between these the ethmoid bone is received. The nasal process is situated between the two internal angular processes. At the internal angular process is a cavity for the caruncula lachrymalis; and at the external, another for the pulley of the major oblique muscle. The foramina are three on each side; one in each superciliary ridge, through which a nerve, artery, and vein, pass to the integuments of the forehead; a second near the middle of the internal side of the orbit, called internal orbitar; the third is smaller, and lies about an inch deeper in the orbit. On the inside of the os frontis there is a ridge which is hardly perceptible at the upper part, but grows more prominent at the bottom, where the foramen cœcum appears; to this ridge the falx is attached. The frontal sinus is placed over the orbit on each side, except at this part the frontal bone is of mean thickness between the parietal and occipital: but the orbitar process is so thin as to be almost transparent.

FRUCTIFICATION. (*Fructificatio;* from *fructus*, fruit, and *facio*, to make.) Under this term are comprehended the flowers and the fruit of a plant. It is a temporary part of plants appropriated to generation, terminating the old vegetable and beginning the new. By the parts of fructification, Sir James Smith observes, each species is perpetually renewed without limits, while all other modes of propagation are but the extension of an individual, and sooner or later terminate in its total extinction. The fructification is therefore essential to vegetables. A plant may be destitute of stem, leaves, or even roots, because if one of these parts be wanting, the others may perform its functions, but it can never be destitute of those organs by which its species is propagated.

Linnæus distinguishes seven parts of fructification, some of which are essential to the very nature of a flower or fruit; others not so indispensably necessary, and therefore are not universal.

1. The *calyx*, or flower-cup, not essential and often absent. See *Calyx.*

2. The *corolla*, or petals, likewise not essential. See *Corolla.*

3. The *stamen* or *stamina*. These are essential. See *Stamen.*

4. The *pistillum*, or *pistilla*, in the centre of the flower, consisting of the rudiments of the fruit, with one or more organs attached to them, and therefore essential. See *Pistillum.*

5. The *pericarpium*, or seed-vessel, wanting in many plants. See *Pericarpium.*

6. The *semen*, or seed, the perfecting of which is the sole end of all the other parts.

7. The *receptaculum*, which must necessarily be present in some form or other. See *Receptaculum*.

FRU'CTUS. (*Fructus, tûs.* m.; *à fruor.*) The fruit of a tree or plant. By this term is understood in botany, the produce of the germen, consisting of the seed-vessel and seed.

Fructus horæi. Summer fruits. Under this term are comprehended strawberries, cherries, currants, mulberries, raspberries, and the like. They possess a sweet sub-acid taste, and are exhibited as dietetic auxiliaries, as refrigerants, antiseptics, attenuants, and aperients. Formerly they were exhibited medicinally in the cure of putrid affections, and to promote the alvine and urinary excretions. The acid which they contain is either the tartaric, oxalic, citric, or mallic, or a mixture of two or more of them with sugar and gluten, starch and a gelatinous substance. Considering them as an article of diet, they afford little nourishment, and are liable to produce flatulencies. To persons of a bilious constitution and rigid fibres, and where the habit is disposed naturally, or from extrinsic causes, to an inflammatory or putrescent state, their moderate and even plentiful use, is salubrious; by those of a cold inactive disposition, where the vessels are lax, the circulation languid, and the digestion weak, they should be used very sparingly. The juices extracted from these fruits by expression, contain their active qualities freed from their grosser indigestible matter. On standing, the juice ferments and changes to a vinous or acetous state. By proper addition of sugar, and by boiling, their fermentative power is suppressed, and their medicinal qualities preserved. The juices of these fruits, when purified from their fæculencies by settling and straining, may be made into syrups, with a due proportion of sugar in the usual way.

FRUIT. See *Fructus*.

Fruits, summer. See *Fructus horæi*.

FRUMENTA'CEOUS. A term applied to all such plants as have a conformity with wheat, either with respect to their fruit, leaves, or ears.

FRUTESCENTIA. (From *fructus*, fruit.) The time at which the fruit arrives at maturity.

FRUTEX. A shrub or plant, which rises with a woody durable stem, but never arrives at the height, or has the appearance of an *arbor*, or tree.

FU'CUS. The name of a genus of plants in the Linnæan system. Class, *Cryptogamia*; Order, *Algæ*.

Fucus digitatus. This fucus grows upon stones and rocks in the sea near the shore. It has several plain, long leaves or sinuses springing from a round stalk, in the manner of fingers when extended. It affords soda.

Fucus esculentus. Edible fucus. Hudson has made this a distinct species, but Linnæus included it under his saccharinus. It grows plentifully in the sea near the shores of Scotland, and also those of Cumberland. It has a broad, plain, simple, sword-shaped leaf, springing from a pinnated stalk.

Fucus helminthocorton. See *Corallina corsicana*.

Fucus palmatus. Handed fucus. This grows in the sea, and consists of a thin-lobed leaf like a hand.

Fucus saccharinus. Sea-belts; so called from the supposed resemblance of its leaves to a belt or girdle. It grows upon rocks and stones by the sea-shore. The leaves are very sweet, and when washed and hung up to dry, will exude a substance like sugar, from whence it was named.

Fucus vesiculosus. The systematic name of the sea-oak. Sea wreck. *Quercus marina.* This sea-weed, the *Fucus—fronde plana dichotoma costata integerrima, vesiculis axillaribus geminis, terminalibus tuberculatis*, of Linnæus, is said to be a useful assistant to sea-water, in the cure of disorders of the glands. Burnt in the open air, and reduced to a black powder, it forms the æthiops vegetabilis, which, as an internal medicine, is similar to burnt sponge.

FULCRUM. A prop or support. This term is applied by Linnæus, not only to those organs of vegetables correctly so denominated, such as tendrils, but also to various other appendages to the herbage of a plant, none of which are universal or essential, nor is there any one plant furnished with them all. Sir James Smith prefers the English term *appendage*, for these organs in general, to *props*, because the latter applies only to one of them.

The greater *props*, or *fulcra* of vegetables, are the roots, trunks, and branches.

To the *lesser* are referred,

1. The *petiolus*, or petiole, which is the fulcrum of the leaf.

2. *Cirrus*, the tendril. See *Cirrus*.

3. The *stolo*, or sucker; a filament, or underground bud, protruded from the root, and sending off radicles into the earth, pushes up a stem resembling the parent plant; as in the strawberry, and *Syringa vulgaris*.

4. *Sarmentum*, the runner, which gives off from the stem, and radicates on that which is nearest to it; as does the *Hedera helix*, or ivy.

The *fulcra of a flower* are the peduncle, scape, and receptacle.

FULI'GO. (*Quasi fumiligo*; from *fumus*, smoke.) *Araxos*; *Asoper*; *Asuoli*. Soot. Wood-soot, *fuligo ligni*, or the condensed smoke from burning wood, has a pungent, bitter, and nauseous taste, and is resolved by chemical analysis into a volatile alkaline salt, an empyreumatic oil, a fixed alkali, and an insipid earth. The tincture prepared from this substance, *tinctura fuliginis*, is recommended as a powerful antispasmodic in hysterical affections.

FULLER'S EARTH. An earth found in large beds in Buckinghamshire and Surrey, composed of silica, alumine, magnesia, lime, muriate of soda, a trace of potassa, and oxide of iron. See *Earth, Fuller's*.

FULMINA'TION. *Fulminatio.* Detonation. A quick and lively explosion of bodies, such as takes place with fulminating gold, fulminating powder, and in the combustion of a mixture of inflammable gas and vital air.

FUMA'RIA. (From *fumus*, smoke, from its juice, when dropped into the eye, producing the same sensations as smoke.)

1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria*. Fumitory.

2. The pharmacopœial name of the common fumitory. See *Fumaria officinalis*.

Fumaria bulbosa. *Aristolochia fabacea.* The root of this plant, *Fumaria—caule simplici, bracteis, longitudine florum*, of Linnæus, was formerly given to restore suppressed menses, and as an anthelmintic.

Fumaria officinalis. The systematic name of the fumitory. *Fumaria*; *Fumus terræ*; *Capnos*; *Herba melancholifuga.* The leaves of this indigenous plant, *Fumaria—pericarpiis monospermis racemosis, caule diffuso*, of Linnæus, are directed for medicinal use by the Edinburgh college; they are extremely succulent, and have no remarkable smell, but a bitter, somewhat saline taste. The infusion of the dried leaves, or the expressed juice of the fresh plant, is esteemed for its property of clearing the skin of many disorders of the leprous kind.

FUMIGA'TION. (*Fumigatio*; from *fumus*, smoke.) The application of fumes, to destroy contagious miasmata or effluvia. The most efficacious substance for this purpose is chlorine; next to it the vapour of nitric acid; and, lastly, that of the muriatic. The fumes of heated vinegar, burning sulphur, or the smoke of exploded gunpowder, deserve little confidence as antiloimics. The air of dissecting rooms should be nightly fumigated with chlorine, whereby their atmosphere would be more wholesome and agreeable during the day.

FUMITORY. See *Fumaria.*

FUMUS. Smoke.

Fumus albus. Mercury.

Fumus citrinus. Sulphur.

Fumus duplex. Sulphur and mercury.

Fumus rubens. Orpiment.

FUNCTION. See *Action.*

FUNGI. (The plural of *fungus.*) An order of the class *Cryptogamia* of Linnæus' system. They cannot probably be said to have any herbage; their substance is fleshy: their parts of fructification are in form of very small capsules buried in their fleshy substance. These seminiferous capsules are on the surface, or in plates, and are called *lamellæ*, or gills, pores, or prickles, and they burst, as in the algæ.

A fungus or mushroom affords the following parts,

1. *Pileus*, the hat, which is the round upper part, or head.

2. The *Umbo*, the knob, or boss, or more prominent part in the centre of the hat.

3. *Lamellæ*, the gills, or membraneous parts on the under side. These are peculiar to the *Agarici.*

4. The *pores*, or small punctures on the under surface, observed only in the genus *Boletus.*

5. *Echini*, or *Aculei*, elevated points on the upper surface of the pileus, noticed in the genus *Hydra* only.

6. *Verrucæ*, warts, observed on the inferior surface.

7. *Stipes*, the stem supporting the hat.

8. *Volva*, the wrapper, or covering, of a membraneous texture, surrounding the stem, and concealing the parts of fructification, and in due time bursting all around, forming a ring upon the stalk; as in *Agaricus campestris.* Linnæus also uses this term for the more fleshy external covering of some other fungi, which is scarcely raised out of the ground, and enfolds the whole plant when young.

9. *Annulus*, the ring, or slender membrane surrounding the stem.

The varieties of the *pileus*, or hat, are,

1. *Planus*, flat.
2. *Convexus*; as in *Boletus bovinus.*
3. *Concavus*; as in *Octospora.*
4. *Umbonatus*, umbo or navel-like; as in *Agaricus conspurcatus.*
5. *Campanulatus*; as in *Agaricus fimitarius.*
6. *Viscidus*, viscid.
7. *Dimidiatus*, half round; as in *Agaricus niveus.*
8. *Squamosus*, covered with coloured scales; as in *Agaricus procerus.*
9. *Squarrosus*, having stiff elevated scales; as in *Agaricus conspurcatus.*

The varieties of the *lamellæ* are,

1. *Equal*; as in *Agaricus crinitus.*
2. *Unequal.*
3. *Branched*, when several run into one; as in *Merulius cantharellus.*
4. *Decurrent*, proceeding down the stem.
5. *Venous*, so small that they appear like elevated veins.
6. *Dimidiate*, half round; as in *Agaricus muscarius.*
7. *Labyrinth-like*; as in *Agaricus quercinus.*

The varieties of the *volva* are,

1. *Simple.*
2. *Double.*
3. *Stellate*, cut several times; as in *Lycopodium stellatum.*

The varieties of the *annulus* are,

1. *Erect*, loose above and fixed below; as in *Agaricus conspurcatus.*
2. *Inverse*, fixed above, free, and bell-like below; as in *Agaricus Mappa.*
3. *Sessile*, fixed only laterally.
4. *Mobile*; as in *Agaricus antiquatus.*
5. *Persistent*, remaining after the perfect formation of the plant.
6. *Evanescent*, disappearing after the complete evolution of the fungus.
7. *Arachnoid*, resembling a slender white web.

The varieties of the *stipes* or stem:

1. *Annulate*, having a ring.
2. *Naked*, without any.
3. *Squamose*, scaly.
4. *Bulbous*; as in *Agaricus separatus.*
5. *Filiform*; as in *Agaricus crinitus.*

FUNGIC ACID. *Acidum fungicum.* The expressed juice of the *boletus juglandis*, *boletus pseudo-igniarius*, the *phallus impudicus*, *merulius cantharellus*, or the *peziza nigra*, being boiled to coagulate the albumen, then filtered, evaporated to the consistence of an extract, and acted on by pure alkohol, leaves a substancee which is called *Fungic acid.*

It is a colourless, uncrystallisable, and deliquescent mass, of a very sour taste. The fungates of potassa and soda are uncrystallisable; that of ammonia forms regular six-sided prisms; that of lime is moderately soluble, and is not affected by the air; that of barytes is soluble in fifteen times its weight of water, and crystallises with difficulty; that of magnesia appears in soluble granular crystals. This acid precipitates from the acetate of lead a white flocculent fungate, which is soluble in distilled vinegar. When insolated, it does not affect solution of nitrate of silver; but the fungates decompose this salt.

FUNGIN. The fleshy part of mushrooms deprived by alkohol and water of every thing soluble.*

FU'NGUS. 1. Proud-flesh. A term in surgery to express any luxuriant formation of flesh on an ulcer.

2. In morbid anatomy it is applied to a disease of the structure of a part which enlarges, is soft, and excrescential.

3. The name of an order of plants in the Linnæan system, belonging to the *Cryptogamia* class.

Fungus hæmatodes. See *Hæmatoma.*

Fungus igniarius. See *Boletus igniarius.*

Fungus laricis. See *Boletus laricis.*

Fungus melitensis. See *Cynomorium.*

Fungus rosaceus. See *Bedeguar.*

Fungus salicis. The willow fungus. See *Boletus suaveolens.*

Fungus sambucinus. See *Peziza auricula.*

Fungus vinosus. The dark cobweb-like fungus, which vegetates in dry cellars, where wine, ale, and the like are kept.

FUNI'CULUS. (*Funiculus*; diminutive of *funis*, a cord.) A little cord.

Funiculus umbilicalis. See *Umbilical cord.*

The funiculus of a seed is a little filament by which the immature seed adheres to the receptacle, seen in *Pisum sativum*, and *Lunaria annua.*

FU′NIS. A rope or cord.

Funis umbilicalis. See *Umbilical cord.*

FUNNEL-SHAPED. See *Infundibuliformis.*

FURCA. A fork or species of armature of plants. See *Aculeus.*

Furce′lla inferior. The ensiform cartilage.

Fu′rcula. The clavicle.

FU′RFUR. 1. Bran.

2. A disease of the skin, in which the cuticle keeps falling off in small scales like bran.

FURFURA′CEOUS. (*Furfuraceus; from furfur*, bran.) A term applied to the bran-like sediment occasionally deposited in the urine.

FURNACE. *Furnus.* The furnaces employed in chemical operations are of three kinds:

1. The *evaporatory furnace*, which has received its name from its use; it is employed to reduce substances into vapour by means of heat, in order to separate the more fixed principles from those which are more volatile.

2. The *reverberatory furnace*, which name it has received from its construction, the flame being prevented from rising; it is appropriated to distillation.

3. The *forge furnace*, in which the current of air is determined by bellows.

FU′ROR. Fury, rage.

Furor uterinus. (From *furo*, to be mad, and *uterus*, the womb.) See *Nymphomania.*

FURU′NCULUS. (From *furo*, to rage; so named from its heat and inflammation before it suppurates.) *Dothein* of Paracelsus. *Chiadus; Chioli.* A boil. An inflammation of a subcutaneous gland, known by an inflammatory tumour that does not exceed the size of a pigeon's egg.

Fusible metal. A combination of three parts of lead with two of tin, and five of bismuth. It melts at 197° Fahr.

FUSIBILITY. The property by which metals and minerals assume the fluid state.

FUSIFORMIS. Fusiform. Spindle-shaped or tapering. Applied to parts of plants, as roots, &c. which penetrate perpendicularly into the earth: as the carrot, parsnep, radish, &c.

FUSION. (*Fusio; from fundo*, to pour out.) A chemical process, by which bodies are made to pass from the solid to the fluid state in consequence of the application of heat. The chief objects susceptible of this operation are salts, sulphur, and metals. Salts are liable to two kinds of fusion: the one which is peculiar to saline matters, is owing to water contained in them, and is called *aqueous fusion;* the other, which arises from the heat alone, is known by the name of *igneous fusion.*

FUSUS. (From *fundo*, to pour out.) Poured out. Applied by Dr. Good to a species of purging *diarrhœa fusa*, in which the fæces are loose, copious, and of a bright yellow colour.

G.

Gabia′num oleum. See *Petroleum rubrum.*

Gabi′rea. A fatty kind of myrrh, mentioned by Dioscorides.

GADOLINITE. A hard black coloured semi-transparent mineral from Sweden, composed of silica, yttria, oxide of cerium, and oxide of iron.

GADUS. The name of a genus of fishes, of the jugular tribe. The following species are brought to the European markets for the use of the table.

Gadus ciliaris. The Baltic torsk. The Icelanders prepare it by salting and drying, when it becomes an article of commerce, under the name of *Tetteling*. Its flesh is white, tender, and well-flavoured.

Gadus morhua. The cod-fish. This well-known fish in our markets, abounds in the northern seas. Its flesh is white, tender, and delicious. When salted it is also well-flavoured, and in general esteem.

Gadus æglefinus. The haddock. An inhabitant of the northern seas of Europe. The larger ones are much esteemed during the winter; the smaller ones for summer use. They are of easy digestion. Salted and dried they are eaten at breakfast as a delicacy.

Gadus minutus. Very small, never exceeding six or seven inches in length. It is found in the Mediterranean, in great abundance, where it is called a *capelau* or officier.

Gadus merlangus. The whiting. A delicate white fish in great abundance in the Irish seas and German ocean.

Gadus pollacius. The whiting pollack found on the rocky coasts of Britain and other parts of Europe, and is in great esteem for the table.

Gadus carbonarius. The coal-fish. Very abundant on the rocky coasts of the northern parts of this island, about the Orkneys, and the coast of Yorkshire, where they become two and three feet long, and constitute the chief support of the poor.

Gadus merluccius. The hake. A native of the North and Mediterranean Seas, not much eaten, except by the poor when dried, when it is called poor John or stock-fish.

Gadus molva. The ling. This grows to the length of five or six feet. It is not so good as the *morhua*, when fresh; but dried and salted is much esteemed, and is the common food of the poor in Cornwall, where it is prepared for exportation.

Gadus lota. The burbot. The flesh of this is considered delicious and of easy digestion.

Gadus brosme. The torsk. This swarms in the seas about the Shetland islands, and forms a considerable article of commerce, either dried, or salted, or packed in barrels.

GALA′CTIA. (From *γαλα*, *lac*, milk; or *γαλακτινος*, *lacteus*, milky.) *Galactirrhœa.* 1. An excess or overflowing of the milk.

2. The name of a genus of diseases, Class, *Genetica;* Order, *Cenotica*, of Good's Nosology. Mislactation. It comprehends five species: viz. *Galactia præmatura; defectura; depravata; errotica; virorum.*

Galactina. (From *γαλα*, milk.) Aliment prepared of milk.

GALACTIRRHŒ′A. (From *γαλα*, milk, and *ρεω*, to flow.) See *Galactia.*

Galacto′des. (From *γαλα*, milk.) In Hinpocrates it signifies both milk-warm and a milky colour.

GALACTO'PHORUS. (From γαλα, milk, and φερω, to bring or carry.) 1. That which has the property of increasing the secretion of the milk.

2. The excretory ducts of the glands of the breasts of women, which terminate in the papilla, or nipple, are so called, because they bring the milk to the nipple.

GALACTOPOIE'TIC. (*Galactopoieticus*; from γάλα, milk, and ποιεω, to make.) Milk making, the faculty of making milk: applied to particular foods, plants, &c.

GALACTOPO'SIA. (From γαλα, milk, and πινω, to drink.) The method of curing diseases by a milk diet.

GALA'NGA. (Perhaps its Indian name.) See *Maranta* and *Kæmpferia*.

Galanga major. See *Kæmpferia galanga.*

Galanga minor. See *Maranta Galanga.*

GALANGAL. See *Maranta Galanga.*

Galangal, English. See *Cyperas longus.*

GALBANUM. (From *chalbanah*, Heb.) See *Bubon galbanum.*

Ga'lbeum. A medical bracelet worn by the Romans.

GA'LBULUS. (The name of the nut, or little round ball of the cypress-tree.) Gærtner applies this term, the classical name of the cypress fruit, which is a true *strobilus*, to a globular spurious berry with three or more seeds formed by the coalescing of a few scales, of a fertile catkin become succulent, which happens in the Juniper.—*Smith.*

Galbulus. (From *galbus*, yellow.) When the skin of the body is naturally yellow.

GA'LDA. A gum-resin, mentioned by old writers, but totally forgot in the present day, and not to be obtained. Externally, it is of a brown colour, but white within, of a hard lamellated structure, and smells and tastes somewhat like elemi. When burnt it gives out an agreeable odour. It was formerly used as a warm stimulating medicine, and applied in plasters as a strengthener.

GA'LEA. (From γαλη, a cat, of the skin of which it was formerly made.) A helmet. 1. In anatomy, the amnios is so called, because it surrounds the fœtus like a helmet.

2. In surgery; a bandage for the head.

3. A species of headache is so called, when it surrounds the head like a helmet.

4. In botany it is applied to upper arched lip of ringent and personate corols. See *Corolla.*

GALEANTHRO'PIA. (This term seems to be from λαλη, a cat, and ανθρωπος, a man.) It is a species of madness, in which a person imagines himself to be a cat, and imitates its manners.

GA'LEGA. (From γαλα, milk: so named because it increases the milk of animals which eat it.) 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria.*

2. The pharmacopœial name of the *Ruta capraria.* See *Galega officinalis.*

Galega officinalis. The systematic name of the goats rue. *Galega. Ruta capraria.* From the little smell and taste of this plant, *Galega leguminibus strictis, erectis; foliolis lanceolatis, striatis, nudus*, of Linnæus, it may be supposed to possess little virtues. In Italy, the leaves are eaten among salads.

Galegæ. A species of senna from the East Indies. The *cassia tora* of Linnæus.

GALE'NA. (From γαλειν, to shine.) The name of an ore formed by the combination of lead with sulphur. A native sulphuret of lead ore.

GALE'NIC. That practice of medicine which conforms to the rules of Galen, and runs much upon multiplying herbs and roots in the same composition, was long called Galenical medicine, after the manner of Galen. It is opposed to chemical medicine, which, by the force of fire, and a great deal of art, fetches out the virtues of bodies, chiefly mineral, into a small compass.

Gale'nium. (From γαληνη, galena.) A cataplasm; in the composition of which was the galena. In Paulus Ægineta it is considered as anodyne.

GALENUS, Claudius, was born at Pergamus, in Asia Minor, in 131. His father, Nicon, having instructed him in the rudiments of knowledge, sent him to attend the best schools of philosophy. Galen soon displayed his judgment by selecting what appeared most rational from the different sects; but he totally rejected the Epicurean system, which was then in fashion. About the age of 17, he began his attachment to the science of medicine, over which he was destined to preside for many centuries with oracular authority. During his youth, he travelled much, that he might converse with the most intelligent physicians of the age, and inform himself concerning the drugs brought from other countries. He resided several years at Alexandria, which was then the great resort of men of science, and the best school of medicine in the world. At the age of 28, returning to his native place, he met with distinguished success in practice: but four years after he attempted to establish himself at Rome. Here he encountered much opposition from his professional brethren, who stigmatized him as a theorist, and even as a dealer in magic; and though he gained the esteem of several men of learning and rank, yet wanting temper and experience sufficient to maintain a successful contest with a numerous and popular party, he was obliged to return to Pergamus within five years, under the pretence of avoiding the plague, which then raged at Rome. He was however soon after sent for to attend the emperors Marcus Aurelius and Lucius Verus, of whom the latter died; and the former conceived so high an opinion of Galen, that subsequently during his German expedition, he committed his two sons to the care of that physician. These princes were seized with fevers, in which Galen having prognosticated a favourable issue, contrary to the opinion of all his colleagues, and having accordingly restored them to health, he attained an eminence of reputation, which enabled him to defy the power, and finally, to ruin the credit, of his former opponents. It is not certain whether he continued at Rome till his death, nor at what precise period this occurred; but Fabricius asserts that he attained the age of 70, which corresponds to the 7th year of Severus; and his writings appear to indicate, that he was still in that city in the early part of this emperor's reign. The greatest part of Galen's life was spent in the zealous pursuit of knowledge, and especially of every thing which might have the least connection with medicine; and he is said to have composed about 750 different essays on such subjects. He appears however to have been too much elated with the consciousness of his superior endowments, and to have behaved rather contemptuously towards his brethren; which may have inflamed their opposition to him. The chief object in his writing appears to be to illustrate those of Hippocrates, which he thought succeeding physicians had misunderstood or misrepresented: in this he has displayed great acuteness and learning, though he has not much increased the stock of practical information. His example too had the unfortunate effect of introducing a taste for minute distinctions and abstract speculations; while the diligent observation of nature, which distinguished the father of medicine, fell into neglect. We must therefore regret that the splendour of Galen's talents so completely dazzled his successors, that, until about the middle of the 17th century, his opinion bore almost undivided sway. Numerous editions of his works, in the original Greek, or translated into Latin, have been printed in modern times.

GALEO'BDOLON. (From γαλεη, *felis*, and βδολος, *crepitus.*) See *Galeopsis.*

GALEO'PSIS. (From καλος, good, and οψις, vision: so called because it was thought good for the sight, or from γαλη, a cat, and οψις, aspect; the flowers gaping like the open mouth of that animal.) *Galeobdolon.* See *Lamium album.*

GALERI'CULUM APONEUROTICUM. A name in old writings for the tendinous expansion which lies over the pericranium.

Galipot. See *Barras.*

GA'LIUM. (From γαλα, milk; some species having the property of coagulating milk.) 1. The name of a genus of plants in the Linnæan system. Class, *Tetrandria;* Order, *Monogynia.*

2. The pharmacopœial name of the herb cheese-rennet, or ladies' bedstraw. See *Galium verum.*

3. A name for madder.

GALIUM ALBUM. The greater ladies' bed-straw. See *Galium mollugo.*

GALIUM APARINE. The systematic name of the goose-grass, and cleaver's bees. Cleavers; Goose-share; Hayriff. *Aparine; Philanthropus; Ampelocarpus; Omphalocarpus; Ixus; Asparine; Asperula.* This plant is common in our hedges and ditches: *Galium—foliis octonis lanceolatis carinatis scabris retrorsum aculeatis, geniculis venosis, fructu hispido,* of Linnæus. The expressed juice has been given with advantage as an aperient and diuretic in incipient dropsies; but the character in which it has of late been chiefly noticed, is that of a remedy against cancer. A tea cup-full, internally, gradually increased to half a pint, two or three times a day, and the herb applied, in cataplasm, externally, has been said to cure cancers. Such beneficial results are not confirmed by the experience of others.

GALIUM MOLLUGO. The systematic name of the greater ladies' bedstraw. *Galium album. Galium—foliis octonis, ovato-linearibus, subserratis, patentissimis, mucronatis; caule flaccido, ramis patentibus* of Linnæus. This herb, with its flowers, is used medicinally. Five ounces, or more of the expressed juice, taken every evening upon an empty stomach, is said to cure epilepsy.

GALIUM VERUM. The systematic name of the true ladies' bed-straw, or cheese-rennet. *Galium* of the pharmacopœias. The tops of this plant, *Galium—foliis octonis, linearibus, sulcatis; ramis floriferis, brevibus,* of Linnæus, were long used as an efficacious medicine in the cure of epilepsy; but, in the practice of the present day, they are abandoned. Indeed, from the sensible qualities of the plant, little can be expected. The leaves and flowers possess the property of curdling milk; it is on that account styled cheese-rennet.

GALL. See *Bile.*

GALL SICKNESS. (See *Febris remittens.*) A popular name for the remitting fever occasioned by marsh miasmata, in the Netherlands, and which proved so fatal to thousands of the English soldiers after the capture of Walcheren in the year 1809. Dr. Lind informs us, that at Middleburg, the capital of Walcheren, a sickness generally reigns towards the latter end of August or the beginning of September, which is always most violent after hot summers. It commences after the rains which fall in the end of July; the sooner it begins the longer it continues, and it is only checked by the coldness of the weather. Towards the end of August and the beginning of September, it is a continual burning fever, attended with a vomiting of bile, which is the *gall sickness.* This fever, after continuing three or four days, intermits and assumes the form of a double tertian; leaving the patient in a fortnight or perhaps sooner. Strangers, that have been accustomed to breathe a dry, pure air, do not recover so quickly. Foreigners in indigent circumstances, such as the Scots and German soldiers, who were garrisoned in the adjacent places, were apt, after those fevers, to have a swelling in the legs, and a dropsy; of which many died.

These diseases are the same with the double tertians common within the tropics. Such as are seized with the gall sickness, have at first some flushes of heat over the body, a loss of appetite, a white, foul tongue, a yellow tinge in the eyes, and a pale colour of the lips. Such as live well, drink wine, and have warm clothes and a good lodging, do not suffer so much during the sickly season as the poor people; however, these diseases are not infectious, and seldom prove mortal to the natives.

Sir John Pringle observes, that the prevailing epidemic of autumn, in all marshy countries, is a fever of an intermitting nature, commonly of a tertian form, but of a bad kind; which, in the dampest places and worst seasons, appears as a double tertian, a remitting, or even an ardent fever. But, however these may vary in their appearance, according to the constitution of the patient and other circumstances, they are all of a similar nature. For though, in the beginning of the epidemic, when the heat, or rather the putrefaction in the air, is the greatest, they assume a continued or a remitting form; yet, by the end of autumn, they usually terminate in regular intermittents.

But, although, in the gall sickness, there is both a redundance and a depravation of the bile, still the disease cannot, with justice, be said to originate wholly from that cause. It is certain, however, that the disease may be continued, and the symptoms aggravated by an increased secretion and putrefaction of the bile, occasioned by the fever. In proportion to the coolness of the season, or the height and dryness of the ground, this disease is milder, remits and intermits more freely, and removes further from the nature of a continued fever. The higher ranks of people in general are the least liable to the diseases of the marshes; for such countries require dry houses, apartments raised above the ground, moderate exercise, without labour, in the sun, or evening damps; a just quantity of fermented liquors, plenty of vegetables and fresh meats. Without such helps, not only strangers but the natives themselves are sickly, especially after hot and close summers. The hardiest constitutions are very little excepted more than others; and hence the British in the Netherlands have always been subject to this fever.

By this disease, the British troops were harassed throughout the war, from 1743 to 1747. It appeared in the month of August, 1743: the paroxysms came on in the evening, with great heat, thirst, a violent headache, and often a delirium. These symptoms lasted most of the night, but abated in the morning, with an imperfect sweat; sometimes with an hæmorrhage of the nose, or looseness. The stomach, from the beginning, was disordered with a nausea and sense of oppression; frequently with a bilious and offensive vomiting. If evacuations were either neglected or too sparingly used, the patient fell into a continued fever, and sometimes grew yellow, as in jaundice. When the season was further advanced, this fever was attended with a cough, rheumatic pains, and sizy blood. The officers, being better accommodated than the common men, and the cavalry, who had cloaks to keep them warm, were not so subject to it; and others, who belonged to the army, but lay in quarters, were least of all affected; and the less in proportion to their being exposed to heats, night damps, and the other fatigues of the service. In this manner did the remitting fever infest the army for the remaining years of the war: and that exactly in proportion to their distance from the marshy places, of which we have several notable instances in Pringle's observations.

GALL-BLADDER. *Vesicula fellis.* An oblong membraneous receptacle, situated under the liver, to which it is attached in the right hypochondrium. It is composed of three membranes, a common, fibrous, and villous. Its use is to retain the bile which regurgitates from the hepatic duct, there to become thicker, more acrid, and bitter, and to send it through the cystic duct, which proceeds from its neck into the ductus communis choledochus, to be sent on to the duodenum.

GALL-STONE. *Calculus biliosus.* Biliary concretion. Hard concrete bodies, formed in the gall-bladder of animals. Of these there are four different kinds.

1. The first has a white colour, and when broken presents crystalline plates, or striæ, brilliant and white like mica, and having a soft, greasy feel. Sometimes its colour is yellow or greenish; and it has constantly a nucleus of inspissated bile. Its specific gravity is inferior to that of water: Gren found the specific gravity of one 0.803. When exposed to a heat considerably greater than that of boiling water, this crystallised calculus softens and melts, and crystallises again when the temperature is lowered. It is altogether insoluble in water; but hot alkohol dissolves it with facility. Alkohol, of the the temperature of 167°, dissolves one-twentieth of its weight of this substance; but alkohol at the temperature of 60°, scarcely dissolves any of it. As the alkohol cools, the matter is deposited in brilliant plates, resembling talc or boracic acid. It is soluble in oil of turpentine. When melted it has the appearance of oil, and exhales the smell of melted wax; when suddenly heated, it evaporates altogether in a thick smoke. It is soluble in pure alkalies, and the solution has all the properties of a soap. Nitric acid also dissolves it; but it is precipitated unaltered by water.

This matter, which is evidently the same with the crystals Cadet obtained from bile, and which he considered as analogous to sugar of milk has a strong resemblance to spermaceti. Like that substance, it is of an oily nature, and inflammable; but it differs from it in a variety of particulars. Since it is contained in bile, it is not difficult to see how it may crystallise in the gall-bladder if it happen to be more abundant than usual; and the consequence must be a gall-stone of this species. Fourcroy found a quantity of the same substance in the dried human liver. He called it *adipocere*.

2. The second species of biliary calculus is of a round or polygonal shape, often of a gray colour externally, and brown within. It is formed of concentric layers of a matter, which seems to be inspissated bile; and there is usually a nucleus of the white crystalline matter at the centre. For the most part, there are many of this species of calculus in the gall-bladder together; indeed it is frequently filled with them. The calculi belonging to this species are often light and friable, and of a brownish-red colour. The gall-stones of oxen, used by painters, belong to this species. These are also adipocere.

3. The third species of calculi are most numerous of all. Their colour is often deep brown or green; and when broken, a number of crystals of the substance resembling spermaceti are observable, mixed with inspissated bile. The calculi belonging to these three species are soluble in alkalies, in soap ley, in alkohol, and in oils.

4. Concerning the fourth species of gall-stone, very little is known with accuracy. Dr. Saunders tells us, that he has met with some gall-stones insoluble both in alkohol and oil of turpentine; some of which do not flame, but become red, and consume to ashes like charcoal. Haller quotes several examples of similar calculi. Gall-stones often occur in the inferior animals, particularly in cows and hogs; but the biliary concretions of these animals have not hitherto been examined with much attention.

Gall-stones often lie quiet; so that until dissection after death, some are never known to exist; but when they are prevented from passing through the gall-ducts, they obstruct the passage of the bile into the intestines, and produce also many inconvenient symptoms, particularly the jaundice.

The diagnostics of this disorder are generally very obscure and uncertain: for other causes produce the same kind of symptoms as those which occur in this disease. The usual symptoms are a loss of appetite, a sense of fulness in the stomach, sickness and vomiting, languor, inactivity, sleepiness; and, if the obstruction continues for a time, there is wasting of the flesh; yellowness of the eyes, skin, and urine; whitish stools; a pain in the pit of the stomach; whilst the pulse remains in its natural state. The pain excited by an obstruction of the gall-ducts, in consequence of gall-stones passing through them, and this not affecting the pulse, is considered as the leading pathognomonic symptom. This pain, in some, is extremely acute, in others there is only a slight uneasiness felt about the region of the liver; but its particular seat is the gall-duct, just where it enters the duodenum. In some patients there is no yellowness of the skin; in others it exists for several months. There is no disease more painful than this, in some instances; it is as frequent as any other affection of the liver; it admits of much relief from medicine, and is not immediately dangerous to the patient. See *Icterus.*

GA'LLA. (From *Gallus*, a river in Bithynia.) A gall. See *Quercus cerris.*

GALLA TURCICA. See *Quercus cerris.*

GALLIC ACID. *Acidum gallicum.* An acid found in vegetable substances possessing astringent properties, but most abundantly in the excrescences termed galls, whence it derives its name. It may be obtained by macerating galls in water, filtering, and suffering the liquor to stand exposed to the air. It will grow mouldy, be covered with a thick glutinous pellicle, abundance of glutinous flocks will fall down, and, in the course of two or three months, the sides of the vessel will appear covered with small yellowish crystals, abundance of which will likewise be found on the under surface of the supernatant pellicle. These crystals may be purified by solution in alkohol, and evaporation to dryness.

Or muriate of tin may be added to the infusion of galls, till no more precipitate falls down; the excess of oxide of tin remaining in the solution, may then be precipitated by sulphuretted hydrogen gas, and the liquor will yield crystals of gallic acid by evaporation.

A more simple process, however, is to boil an ounce of powdered galls in sixteen ounces of water to eight, and strain. Dissolve two ounces of alum in water, precipitate the alumina by carbonate of potassa; and after edulcorating it completely by repeated ablutions, add it to the decoction, frequently stirring the mixture with a glass rod. The next day filter the mixture, wash the precipitate with warm water, till this will no longer blacken sulphate of iron; mix the washings with the filtered liquor, evaporate, and the gallic acid will be obtained in fine needled crystals.

These crystals obtained in any of these ways, however, are contaminated with a small portion of extractive matter; and to purify them they may be placed in a glass capsule in a sand-heat, and sublimed into another capsule inverted over this, and kept cool.

The gallic acid placed on a red-hot iron, burns with flame, and emits an aromatic smell, not unlike that of benzoic acid. It is soluble in 20 parts of cold water, and in three parts at a boiling heat. It is more soluble in alkohol, which takes up an equal weight if heated, and one-fourth of its weight cold.

It has an acido-astringent taste, and reddens tincture of litmus. It does not attract humidity from the air.

This acid, in its combinations with the salifiable bases, presents some remarkable phenomena. If we pour its aqueous solution by slow degrees into lime, barytes, or strontites water, there will first be formed a greenish-white precipitate. As the quantity of acid is increased, the precipitate changes to a violet hue, and eventually disappears. The liquid has then acquired a reddish tint. Among the salts, those only of black oxide and red oxide of iron, are decomposed by the pure gallic acid. It forms a blue precipitate with the first, and a brown with the second. But when this acid is united with tannin, it decomposes almost all the salts of the permanent metals.

Concentrated sulphuric acid decomposes and carbonizes it; and the nitric acid converts it into malic and oxalic acids.

United with barytes, strontian, lime and magnesia, it forms salts of a dull yellow colour, which are little soluble, but more so if their base be in excess. With alkalies it forms salts that are not very soluble in general.

Its most distinguishing characteristic is its great affinity for metallic oxides, so as, when combined with tannin, to take them from powerful acids. The more readily the metallic oxides part with their oxygen, the more they are alterable by the gallic acid. To a solution of gold, it imparts a green hue; and a brown precipitate is formed, which readily passes to the metallic state, and covers the solution with a shining golden pellicle. With nitric solution of silver, it produces a similar effect. Mercury it precipitates of an orange-yellow: copper, brown; bismuth, of a lemon colour; lead, white; iron, black. Platina, zinc, tin, cobalt, and manganese, are not precipitated by it.

The gallic acid is of extensive use in the art of dyeing, as it constitutes one of the principal ingredients in all the shades of black, and is employed to fix or improve several other colours. It is well known as an ingredient in ink.

GA'LLICUS. Belonging to the French: applied to the venereal disease. See *Lues venerea.*

GALLINA'GO. (Diminutive of *gallus*, a cock.) 1. The woodcock.

2. An enimence within the prostate gland is called *caput callinaginis*, from its fancied resemblance to a woodcock's head.

GALLI'TRICHIS. Corrupted from *callitrichis*, or *callitrichum.* See *Callitriche.*

GA'LLIUM. See *Galium.*

GA'LVANISM. A professor of anatomy, in the university of Bologna, named *Galvani*, was one day making experiments on electricity in his elabratory: near the machine were some frogs that had been flayed, the limbs of which became convulsed every time a spark was drawn from the apparatus. Galvani, surprised at this phenomenon, made it a subject of investigation, and discovered that metals, applied to the nerves and muscles of these animals occasioned powerful and sudden contractions, when disposed in a certain manner. He gave the name of animal electricity to this order of new phenomena, from the analogy that he considered existing between these effects and those produced by electricity.

The name animal electricity has been superseded, notwithstanding the great analogy that exists between the effects of electricity and those of Galvanism, in favour of the latter term; which is not only more applicable to the generality of the phenomena, but likewise serves to perpetuate the memory of the discoverer.

In order to give rise to Galvanic effects in animal bodies, it is necessary to establish a communication between two points of one series of nervous and muscular organs. In this mannner a circle is formed, one arch of which consists of the animal parts, rendered the subject of experiment, while the other arch is composed of excitatory instruments, which generally consist of several pieces, some placed under the animal parts called supporters, others destined to establish a communication between the latter, are called conductors. To form a complete Galvanic circle, take the thigh of a frog, deprived of its skin; detach the crural nerve, as far as the knee; put it on a piece of zinc; put the muscles of the leg on a piece of silver; then finish the excitatory arch, and complete the Galvanic circle by establishing a communication by means of the two supporters; by means of iron or copper-wire, pewter or lead. The instant that the communicators touch the two supporters, a part of the animal arch formed by the two supporters will be convulsed. Although this disposition of the animal parts, and of Galvanic instruments, be most favourable to the development of the phenomena, yet the composition of the animal and excitatory arch may be much varied. Thus contractions are obtained, by placing the two supporters under the nerve, and leaving the muscle out of the circle, which proves that nerves essentially constitute the animal arch.

It is not necessary for nerves to be entire in order to produce contractions. They take place whether the organs be tied or cut through, provided there exists a simple contiguity between the divided ends. This proves that we cannot strictly conclude what happens in muscular action, from that which takes place in Galvanic phenomena; since, if a nerve be tied, or divided, the muscles on which this is distributed lose the power of action.

The cuticle is an obstacle to Galvanic effects; they are always feebly manifested in parts covered by it. When it is moist, fine, and delicate, the effect is not entirely interrupted. Humboldt, after having detached the cuticle from the posterior part of the neck and back, by means of two blisters, applied plates of metal to the bare cutis, and, at the moment of establishing a communication, he experienced sharp prickings, accompanied with a sero-sanguinous discharge.

If a plate of zinc be placed under the tongue, and a flat piece of silver on its superior surface, on making them touch each other, an acerb taste will be perceived, accompanied with a slight trembling.

The excitatory arch may be constructed with three, two, or even one metal only, with alloys, amalgams, or other metallic or mineral combinations, carbonated substances, &c. It is observed that metals which are in general the most powerful excitors, induce contractions so much the more as they have an extent of surface. Metals are all more or less excitants; and it is observed that zinc, gold, silver, pewter, are of the highest rank; then copper, lead, nickle, antimony, &c.

Galvanic susceptibility, like muscular irritability, is exhausted by too long continued exercise, and is recruited by repose. Immersion of nerves and muscles in alkohol and opiate solutions diminishes, and even destroys, this susceptibility, in the same manner, doubtless, as the immoderate use of these substances in the living man blunts, and induces paralysis in muscular action. Immersion in oxymuriatic acid restores the fatigued parts, to be again acted on by the stimulus. Animals killed by the repeated discharge of an electric battery, acquire an increase of Galvanic susceptibility; and this property subsists unchanged in animals destroyed by submersion in mercury, pure hydrogen gas, azote, and ammonia; and finally, it is totally annihilated in animals suffocated by the vapour of charcoal.

Galvanic susceptibility is extinct in the muscles of animals of warm blood, in proportion as vital heat is dissipated; sometimes even when life is terminated in convulsions, contractility cannot be put into action, although warmth be not completely gone, as though the vital property were consumed by the convulsion, amidst which the animals had expired. In those of cold blood, on the contrary, it is more durable. The thighs of frogs, long after being separated from every thing, and even to the instant of incipient putrefaction, are influenced by Galvanic stimuli; doubtless, because irritability, in these animals, is less intimately connected with respiration, and life more divided among the different organs, which have less occasion to act on each other for the execution of its phenomena. The Galvanic chain does not produce sensible actions (that is, contractions,) until the moment it is completed, by establishing a communication with the parts constituting it. During the time it is complete, that is, throughout the whole space of time that the communication remains established, every thing remains tranquil; nevertheless, Galvanic influence is not suspended; in fact, excitability is evidently increased, or diminished, in muscles that have been long continued in the Galvanic chain, according to the difference of the reciprocal situation of the connecting metals.

If silver has been applied to nerves, and zinc to muscles, the irritability of the latter increases in proportion to the time they have remained in the chain. By this method, the thighs of frogs have been revivified in some degree, and afterwards become sensible to stimuli, that before had ceased to act on them. By distributing the metals in an inverse manner, applying zinc to nerves and silver to muscles, an effect absolutely contrary is observed; and the muscles that possess the most lively irritability when placed in the chain, seem to be rendered entirely paralytic if they remain long in this situation.

This difference evidently depends on the direction of the Galvanic fluid, determined towards the muscles or nerves, according to the manner in which these metals are disposed, and this is of some importance to be known for the application of Galvanic means to the cure of diseases.

Galvanic Pile.—Volta's apparatus is as follows:—

Raise a pile, by placing a plate of zinc, a flat piece of wet card, and a plate of silver, successively; then a second piece of zinc, &c. until the elevation is several feet high; for the effects are greater in proportion to its height; then touch both extremities of the pile, at the same instant, with one piece of iron wire; at the moment of contact, a spark is excited from the extremities of the pile, and luminous points are often perceived at different heights, where the zinc and silver come into mutual contact. The zinc end of this pile appears to be negatively electrified; that formed by the silver, on the contrary, indicates marks of positive electricity.

If we touch both extremities of the pile, after having dipped our hands into water, or, what is better, a saline solution, a commotion, followed by a disagreeable prickling in the fingers and elbow, is felt.

If we place in a tube filled with water, and hermetically closed by two corks, the extremities of two wires of the same metal which are in contact at the other extremity, one with the summit, the other with the base of the pile; these ends, even when separated only by the space of a few lines, experience evident changes at the instant the extremities of the pile are touched; the wire in contact with that part of the pile composed of silver becomes covered with bullæ of hydrogen gas; that which touches the extremity formed by zinc, becomes oxidized, or gives off oxygen gas. Fourcroy attributes this phenomenon to the decomposition of water by the Galvanic fluid, which abandons the oxygen to the metal that touches the positive extremity of the pile; then conducts the other gas invisibly to the end of the other wire, there to be disengaged.

Galvanic Trough.—This is a much more convenient apparatus. Plates of two metals, commonly zinc and copper, are fastened together, and cemented into a wooden trough, so as to form a number of cells; or earthen-ware troughs with partitions being procured, the metals, connected by a slip, are suspended over these, so that in each cell, except at the ends, there is a plate of each metal; then a diluted acid, (usually the sulphuric, nitric, or muriatic, mixed with from twelve to twenty parts of water,) is poured into the trough. It is necessary that the metals be placed in the same order throughout, or one series will counteract another. The zinc end becomes negative, the copper positive; and the power is in proportion to the number of the series; and several such troughs may be connected together, so as to form a most powerful apparatus.

From the number of experiments of Davy, many new and important facts have been established, and Galvanism has been found one of the most powerful agents in chemistry: by its influence, platina wire has been melted; gold, silver, copper, and most of the metals, have easily been burnt; the fixed alkalies, and many of the earths have been made to appear as consisting of a metallic base, and oxygen; compound substances, which were before extremely difficult to decompose, are now, by the aid of Galvanism, easily resolved into their constituents.

The galvanic influence has been considered by some practitioners as likely to increase the nervous influence in paralyzed and debilitated states of the muscular system, and many ingenious ways of applying it have been resorted to; but it does not seem to have been useful. Dr. Ure's observations and experiments on this subject and on galvanism are highly interesting. The following account of them is extracted from his Chemical Dictionary. "Many experiments," he observes, "have been performed, in this country and abroad, on the bodies of criminals, soon after their execution. Vassali, Julio, and Rossi, made an ample set, on several bodies decapitated at Turin. They paid particular attention to the effect of galvanic electricity on the heart, and other involuntary muscles: a subject of much previous controversy. Volta asserted, that these muscles are not at all sensible to this electric power. Fowler maintained, that they were affected; but with difficulty and in a slight degree. This opinion was confirmed by Vassali; who further showed, that the muscles of the stomach, and intestines, might thus also be excited. Aldini, on the contrary declared, that he could not affect the heart by his most powerful galvanic arrangements."

Most of the above experiments were however made, either without a voltaic battery, or with piles, feeble in comparison with those now employed. Those indeed performed on the body of a criminal, at New-gate, in which the limbs were violently agitated; the eyes opened and shut; the mouth and jaws worked about, and the whole face thrown into frightful convulsions, were made by Aldini, with, I believe, a considerable series of voltaic plates.

A circumstance of the first moment, in my opinion, has been too much overlooked in experiments of this kind,—that a muscular mass through which the galvanic energy is directly transmitted, exhibits very weak contractile movements, in comparison with those which can be excited by passing the influence along the principal nerve of the muscle. Inattention to this important distinction, I conceive to be the principal source of the slender effects hitherto produced in such experiments on the heart, and other muscles, independent of the will. It ought also to be observed, that too little distinction has been made between the positive and negative poles of the battery; though there are good reasons for supposing, that their powers on muscular contraction are by no means the same.

According to Ritter, the electricity of the positive pole augments, while the negative diminishes the actions of life. Tumefaction of parts is produced by the former; depression by the latter. The pulse of the hand, he says, held a few minutes in contact with the positive pole, is strengthened; that of the one in contact with the negative is enfeebled: the former is accompanied with a sense of heat; the latter with a feeling of coldness. Objects appear to a positively electrified eye, larger, brighter, and red; while to one negatively electrified, they seem smaller, less distinct, and bluish,—colours indicating opposite extremities of the prismatic spectrum. The acid and alkaline tastes, when the tongue is acted on in succession by the two electricities, are well known, and have been ingeniously accounted for by Sir H. Davy, in his admirable Bakerian Lectures. The smell of oxymuriatic acid, and of ammonia, are said by Ritter to be the opposite odours, excited by the two opposite poles; as a full body of sound and a sharp tone are the corresponding effects on the ears. These experiments require verification.

Consonant in some respects, though not in all, with these statements, are the doctrines taught by a London practitioner, experienced in the administration of medical electricity. He affirms, that the influence of the electrical fluid of our common machines, in the cure of diseases, may be referred to three distinct heads; first, the form of *radii*, when projected from a point positively electrified; secondly, that of a star, or the negative fire, concentrated on a brass ball; thirdly, the Leyden explosion. To each of these forms he assigns a specific action. The first acts as a sedative, allaying morbid activity; the second as a stimulant; and the last has a deobstruent operation, in dispersing chronic tumours. An ample narrative of cases is given in confirmation of these general propositions. My own experience leads me to suppose, that the negative pole of a voltaic battery gives more poignant sensations than the positive.

The most precise and interesting researches on the relation between voltaic electricity and the phenomena of life, are those contained in Dr. Wilson Philip's Dissertations in the Philosophical Transactions, as well as in his Experimental Inquiry into the Laws of the Vital Functions, more recently published.

In his earlier researches he endeavoured to prove, that the circulation of the blood, and the action of the involuntary muscles, were independent of the nervous influence. In a late paper, read in January 1816, he showed the immediate dependence of the secretory functions on the nervous influence.

The eighth pair of nerves distributed to the stomach, and subservient to digestion, were divided by incisions in the necks of several living rabbits. After the operation, the parsley which they ate remained without alteration in their stomachs; and the animals, after evincing much difficulty of breathing, seemed to die of suffocation. But when in other rabbits, similarly treated, the galvanic power was transmitted along the nerve, below its section, to a disc of silver, placed closely in contact with the skin of the animal, opposite to its stomach, no difficulty of breathing occurred. The voltaic action being kept up for twenty-six hours, the rabbits were then killed, and the parsley was found in as perfectly digested a state, as that in healthy rabbits fed at the same time; and their stomachs evolved the smell peculiar to that of a rabbit during digestion. These experiments were several times repeated with similar results.

Hence it appears that the galvanic energy is capable of supplying the place of the nervous influence, so that, while under it, the stomach, otherwise inactive, digests food as usual. I am not, however, willing to adopt the conclusion drawn by its ingenious author, that the 'identity of galvanic electricity and nervous influence is established by these experiments.' They clearly show a remarkable analogy between these two powers, since the one may serve as a substitute for the other. It might possibly be urged by the anatomist, that as the stomach is supplied by twigs of other nerves, which communicate under the place of Dr. Philip's section of the *par vagum*, the galvanic fluid may operate merely as a powerful stimulus, exciting those slender twigs to perform such an increase of action, as may compensate for the want of the principal nerve. The above experiments were repeated on dogs, with like results; the battery never being so strong as to occasion painful shocks.

The removal of dyspnœa, as stated above, led him to try galvanism as a remedy in asthma. By transmitting its influence from the nape of the neck to the pit of the stomach, he gave decided relief in every one of twenty-two cases, of which four were in private practice, and eighteen in the Worcester Infirmary. The power employed varied from ten to twenty-five pairs.

The general inferences deduced by him from his multiplied experiments, are, that voltaic electricity is capable of effecting the formation of the secreted fluids, when applied to the blood in the same way in which the nervous influence is applied to it; and that it is capable of occasioning an evolution of caloric from arterial blood. When the lungs are deprived of the nervous influence, by which their function is impeded, and even destroyed, when digestion is interrupted, by withdrawing this influence from the stomach, these two vital functions are renewed by exposing them to the influence of a galvanic trough. 'Hence,' says he, 'galvanism seems capable of performing all the functions of the nervous influence in the animal economy; but obviously it cannot excite the functions of animal life, unless when acting on parts endowed with the living principle.'

These results of Dr. Philip have been recently confirmed by Dr. Clarke Abel, of Brighton, who employed, in one of the repetitions of the experiments, a comparatively weak, and in the other a considerable power of galvanism. In the former, although the galvanism was not of sufficient power to occasion evident digestion of the food, yet the efforts to vomit, and the difficulty of breathing, constant effects of dividing the eighth pair of nerves, were prevented by it. These symptoms recurred when it was discontinued, and vanished on its reapplication. 'The respiration of the animal,' he observes, 'continued quite free during the experiment, except when the disengagement of the nerves from the tin-foil rendered a short suspension of the galvanism necessary during their readjustment.' 'The non-galvanised rabbit breathed with difficulty, wheezed audibly, and made frequent attempts to vomit.' In the latter experiment, in which the greater power of galvanism was employed, digestion went on as in Dr. Philip's experiments.—*Jour. Sc.* ix.

Gallois, an eminent French physiologist, had endeavoured to prove, that the motion of the heart depends entirely upon the spinal marrow, and immediately ceases when the spinal marrow is removed or destroyed. Dr. Philip appears to have refuted this notion, by the following experiments. Rabbits were rendered insensible by a blow on the occiput; the spinal marrow and brain were then removed, and the respiration kept up by artificial means; the motion of the heart, and the circulation, were carried on as usual. When spirit of wine, or opium, was applied to the spinal marrow or brain, the rate of the circulation was accelerated.

A middle-sized, athletic, and extremely muscular man, about 30 years of age, was the subject of the following highly interesting experiments. He was suspended from the gallows nearly an hour, and made no convulsive struggle after he dropped; while a thief, executed along with him, was violently agitated for a considerable time. He was brought to the anatomical theatre of our university in about ten minutes after he was cut down. His face had a perfectly natural aspect, being neither livid nor tumefied; and there was no dislocation of his neck.

Dr. Jeffray, the distinguished professor of anatomy, having on the preceding day requested me (says Dr. Ure) to perform the galvanic experiments, I sent to his theatre with this view, next morning, my *minor* voltaic battery, consisting of 270 pairs of four inch plates, with wires of communication, and pointed metallic rods with insulating handles, for the more commodious application of the electric power. About five minutes before the police officers arrived with the body, the battery was charged with a dilute nitro-sulphuric acid, which speedily brought it into a state of intense action. The dissections were skilfully executed by Mr. Marshall, under the superintendence of the professor.

Exp. 1. A large incision was made into the nape of the neck, close below the *occiput*. The posterior half of the *atlas vertebra* was then removed by bone forceps, when the spinal marrow was brought into view. A profuse flow of liquid blood gushed from the wound, inundating the floor. A considerable incision was at the same time made in the left hip, through the great gluteal muscle, so as to bring the sciatic nerve into sight; and a small cut was made in the heel. From neither of these did any blood flow. The pointed rod connected with one end of the battery, was now placed in contact with the spinal marrow, while the other rod was applied to the sciatic nerve. Every muscle of the body was immediately agitated with convulsive movements, resembling a violent shuddering from cold. The left side was most powerfully convulsed at each renewal of the electric contact. On moving the second rod from the hip to the heel, the knee being previously bent, the leg was thrown out with such violence as nearly to overturn one of the assistants, who in vain attempted to prevent its extension.

Exp. 2. The left phrenic nerve was now laid bare at the outer edge of the *sterno-thyroideus* muscle, from three to four inches above the clavicle; the cutaneous incision having been made by the side of the sterno-cleido-mastoideus. Since this nerve is distributed to the diaphragm, and since it communicates with the heart through the eighth pair, it was expected, by transmitting the galvanic power along it, that the respiratory process would be renewed. Accordingly, a small incision having been made under the cartilage of the seventh rib, the point of the one insulating rod was brought into contact with the great head of the diaphragm, while the other point was applied to the phrenic nerve in the neck. This muscle, the main agent of respiration, was instantly contracted, but with less force than was expected. Satisfied, from ample experience on the living body, that more powerful effects can be produced in galvanic excitation, by leaving the extreme communicating rods in close contact with the parts to be operated on, while the electric chain or circuit is completed by running the end of the wires along the top of the plates in the last trough of either pole, the other wire being steadily immersed in the last cell of the opposite pole, I had immediate recourse to this method. The success of it was truly wonderful. Full, nay, laborious breathing, instantly commenced. The chest heaved, and fell; the belly was protruded, and again collapsed, with the relaxing and retiring diaphragm. This process was continued, without interruption, as long as I continued the electric discharges.

In the judgment of many scientific gentlemen who witnessed the scene, this respiratory experiment was perhaps the most striking ever made with a philosophical apparatus. Let it also be remembered, that for full half an hour before this period, the body had been well nigh drained of its blood, and the spinal marrow severely lacerated. No pulsation could be perceived meanwhile at the heart or wrist; but it may be supposed, that but for the evacuation of the blood,—the essential stimulus of that organ,—this phenomenon might also have occurred.

Exp. 3. The supra-orbital nerve was laid bare in the forehead, as it issues through the supraciliary *foramen*, in the eyebrow: the one conducting rod being applied to it, and the other to the heel, most extraordinary grimaces were exhibited every time that the electric discharges were made, by running the wire in my hand along the edges of the last trough, from the 220th to the 270th pair of plates: thus fifty shocks, each greater than the preceding one, were given in two seconds. Every muscle in his countenance was simultaneously thrown into fearful action; rage, horror, despair, anguish, and ghastly smiles, united their hideous expression in the murderer's face, surpassing far the wildest representations of a Fuseli or a Kean. At this period several of the spectators were forced to leave the apartment from terror or sickness, and one gentleman fainted.

Exp. 4. The last galvanic experiment consisted in trasmitting the electric power from the spinal marrow to the ulnar nerve, as it passes by the internal condyle at the elbow: the fingers now moved nimbly, like those of a violin performer; an assistant, who tried to close the fist, found the hand to open forcibly, in spite o f his efforts. When the one rod was applied to a slight incision in the tip of the fore-finger, the fist being previously clenched, that finger extended instantly; and from the convulsive agitation of the arm, he seemed to point to the different spectators, some of whom thought he had come to life.

About an hour was spent in these operations.

In deliberating on the above galvanic phenomena, we are almost willing to imagine, that if, without cutting into and wounding the spinal marrow and blood vessels in the neck, the pulmonary organs had been set a-playing at first (as I proposed,) by electrifying the phrenic nerve, (which may be done without any dangerous incision,) there is a probability that life might have been restored. This event, however little desirable with a murderer, and perhaps contrary to law, would yet have been pardonable in one instance, as it would have been highly honourable and useful to science. From the accurate experiments of Dr. Philip, it appears, that the action of the diaphragm and lungs is indispensable towards restoring the suspended action of the heart and great vessels, subservient to the circulation of the blood.

It is known, that cases of death-like lethargy, or suspended animation, from disease and accidents, have occurred, where life has returned after longer interruption of its functions than in the subject of the preceding experiments. It is probable, when apparent death supervenes from suffocation with noxious gases, &c. and when there is no organic læsion, that a judiciously directed galvanic experiment will, if any thing will, restore the activity of the vital functions. The plans of administering voltaic electricity hitherto pursued in such cases, are, in my humble apprehension, very defective. No advantage, we perceive, is likely to accrue from passing electric discharges across the chest, directly through the heart and lungs. On the principles so well developed by Dr. Philip, and now illustrated on Clydesdale's body, we should transmit along the channel of the nerves, that substitute for nervous influence, or that power which may perchance awaken its dormant faculties. Then, indeed, fair hopes may be formed of deriving extensive benefit from galvanism; and of raising this wonderful agent to its expected rank among the ministers of health and life to man.

I would, however, beg leave to suggest another nervous channel, which I conceive to be a still readier and more powerful one, to the action of the heart and lungs, than the phrenic nerve. If a longitudinal incision be made, as is frequently done for aneurism, through the integuments of the neck at the outer edge of the *sterno-mastoideus* muscle, about half-way between the clavicle and angle of the lower jaw; then, on turning over the edge of this muscle, we bring into view the throbbing carotid, on the outside of which, the *par vagum*, and great sympathetic nerve, lie together in one sheath. Here, therefore, they may both be directly touched and pressed by a blunt metallic conductor. These nerves communicate directly, or indirectly, with the phrenic; and the superficial nerve of the heart is sent off from the sympathetic.

Should, however, the phrenic nerve be taken, that of the left side is the preferable of the two. From the position of the heart, the left phrenic differs a little in its course from the right. It passes over the *pericardium*, covering the *apex* of the heart.

While the point of one metallic conductor is applied to the nervous cords above described, the other knob ought to be firmly pressed against the side of the person, immediately under the cartilage of the seventh rib. The skin should be moistened with a solution of common salt, or, what is better, a hot saturated solution of sal-ammoniac, by which means, the electric energy will be more effectually conveyed through the cuticle so as to complete the voltaic chain.

To lay bare the nerves above described, requires, as I have stated, no formidable incision, nor does it demand more anatomical skill, or surgical dexterity, than every practitioner of the healing art ought to possess. We should always bear in mind, that the subject of experiment is at least insensible to pain; and that life is at stake, perhaps irrecoverably gone. And assuredly, if we place the risk and difficulty of the operations in competition with the blessings and glory consequent on success, they will weigh as nothing, with the intelligent and humane. It is possible, indeed, that two small brass knobs, covered with cloth moistened with solution of sal ammoniac, pressed above and below, on the place of the nerve, and the diaphragmatic region, may suffice, without any surgical operation: it may first be tried.

Immersion of the body in cold water accelerates greatly the extinction of life arising from suffocation; and hence less hopes need be entertained of recovering drowned persons after a considerable interval, than when the vital heat has been suffered to continue with little abatement. None of the ordinary practices judiciously enjoined by the Humane Society, should ever on such occasions be neglected. For it is surely culpable to spare any pains, which may contribute, in the slightest degree, to recall the fleeting breath of man to its cherished mansion.

My attention has been again particularly directed to this interesting subject, by a very flattering letter which I lately received from the learned Secretary of the Royal Humane Society.

In the preceding account, I had accidentally omitted to state a very essential circumstance relative to the electrisation of Clydesdale. The paper indeed was very rapidly written, at the busiest period of my public prelections, to be presented to the society, as a substitute for the essay of an absent friend, and was sent off to London the morning after it was read.

The positive pole or wire connected with the zinc end of the battery, was that which I applied to the nerve; and the negative, or that connected with the copper end, was that which I applied to the muscles. This is a matter of primary importance, as the following experiments will prove.

Prepare the posterior limbs of a frog for voltaic electrisation, leaving the crural nerves connected, as usual, to a detached portion of the spine. When the excitability has become nearly exhausted, plunge the limbs into the water of one wine-glass, and the crural nerves with their pendent portion of spine into that of the other. The edges of the two glasses should be almost in contact. Then taking a rod of zinc in one hand, and a rod of silver (or a silver tea-spoon) in the other, plunge the former into the water of the limbs' glass, and the latter into that of the nerves' glass, without touching the frog itself, and gently strike the dry parts of the bright metals together. Feeble convulsive movements, or mere twitching of the fibres, will be perceived at every contact. Reverse now the position of the metalic rods, that is, plunge the zinc into the nerves' glass, and the silver into the other. On renewing the contact of the dry surfaces of the metal now, very lively convulsions will take place; and if the limbs are skilfully disposed in a narrowish conical glass, they will probably spring out to some distance. This interesting experiment may be agreeably varied in the following way, with an assistant operator: let that person seize, in the moist fingers of his left hand, the spine and nervous cords of the prepared frog; and in those of the right hand, a silver rod; and let the other person lay hold of one of the limbs with his right hand, while he holds a zinc rod in the moist fingers of the left. On making the metallic contact, feeble convulsive twitchings will be perceived as before. Holding still the frog as above, let them merely exchange the pieces of metal. On renewing the contacts now, lively movements will take place, which become very conspicuous, if one limb be held nearly horizontal, while the other hangs freely down. At each touch of the voltaic pair, the drooping limb will start up, and strike the hand of the experimenter.

It is evident, therefore, that for the purposes of resuscitating dormant irritability of nerves, or contractility of their subordinate muscles, the positive pole must be applied to the former, and the negative to the latter."—*Ure's Chemical Dictionary.*

GAMBOI'DEA. See *Stalagmitis.*

GA'MMA. (From the letter Γ, *gamma*, which it resembles.) A surgical instrument for cauterising a hernia.

GAMPHE'LE. (From γαμψος, crooked.) The cheek. The jaw.

GA'NGAMON. (From γαγγαμη, a fishing-net, which it was said to resemble.) 1. A name of the omentum.

2. Some call the contexture of nerves about the navel by this name.

GA'NGLION. (Γαγγλιον, a knot.) A knot. 1. In anatomy it is applied to a natural knot-like enlargement, in the course of a nerve.

2. In surgery it is an encysted tumour, formed in the sheath of a tendon, and containing a fluid like the white of an egg. It most frequently occurs on the back of the hand or foot.

GA'NGRENE. (Γαγγραινα; from γραω, to feed upon: so named from its eating away the flesh.) *Gangrena.* See *Mortification.*

GA'RAB. An Arabic name for the disorder of the eyes. See *Ægylops.*

GARCI'NIA. (So called in honour of Dr. Garcin, who accurately described it.) The name of a genus of plants in the Linnæan system. Class, *Dodecandria;* Order, *Monogynia.*

GARCINIA MANGOSTANA. The systematic name of the mangosteen tree. The mangosteen is a fruit about the size of an orange, which grows in great abundance on this tree in Java and the Molucca islands. According to the concurring testimonies of all travellers, it is the most exquisitely flavoured, and the most salubrious of all fruits, it being such a delicious mixture of the tart and sweet. The flesh is juicy, white, almost transparent, and of a more delicate and agreeable flavour than the righest grape. It is eaten in almost every disorder, and the dried bark is used medicinally in dysenteries and tenesmus, and a strong decoction of it is much esteemed as a gargle in ulcerated sore throats.

GA'RGALE. Γαργαλη. *Gargolos; Gargalismos.* Irritation, or stimulation.

GARGA'REON. (Hebrew.) The uvula, or glandulous body, which hangs down into the throat.

GA'RGARISM. See *Gargarisma.*

GARGARI'SMA. (*Gargarisma, atis.* n.; and *Gargarismus, i.* m.; and *Gargarismum, i.* n.; from γαργαριζω, to gargle.) A gargle or wash for the throat.

GARGARISMUM. See *Gargarisma.*

GA'RGATHUM. A bed on which lunatics, &c. were formerly confined.

GARGLE. See *Gargarisma.*

GARLIC. See *Allium.*

GARNET. Professor Jameson divides this mineral genus into three species: the pyramidal garnet, dodecahedral garnet, and prismatic garnet.

1. The *Pyramidal* contains three sub-species; Vesuvian, Egeran, Gehlenite.

2. The *Dodecahedral* contains nine sub-species; Pyreneite, Grossulare, Melanite, Pyrope, Garnet, Allochroite, Colophonite, Cinnamon-stone, Helvin.

3. The *Prismatic;* the grenatite. Of the garnet proper, there are two species:

1. The precious or noble garnet.
2. The common garnet.

GARNET, THOMAS, was born in 1766, at Casterton in Westmoreland. After serving his time to a surgeon and apothecary, he went to study at Edinburgh, where he took his degree at twenty-two, and then attended the London hospitals for two years. In 1790 he settled at Bradford, and began to give private lectures on Philosophy and Chemistry; and here he wrote his Treatise on the Horley Green Spa. But in the following year he removed to Knaresborough, and soon after published an Analysis of the different Waters of Harrowgate, which place he visited during the summer season. About this period he formed the design of going to America; but while waiting to take his passage at Liverpool, he was solicited to deliver some lectures there, which were so favourably received, that he was induced to repeat his course at various other places; and at length the professorship at Anderson's Institution in Glasgow was offered him, where he began lecturing in 1796. Two years after he made a tour to the Highlands, of which he subsequently published an account. On the formation of the Royal Institution in London, he was invited by Count Rumford to become the lecturer there; he accepted the appointment, and the room was crowded with persons of the first distinction and fashion. He then turned his thoughts more seriously to the practice of his profession, as likely to afford the most permanent support; but his prospects were cut short by death about the middle of the year 1802. A posthumous volume, entitled "Zoonomia," was published for the benefit of his family.

Ga'ron. Γαρον. A kind of pickle prepared of fish; at first it was made from a fish, which the Greeks call *Garos*; but the best was made from mackarel. Among the moderns, *garum* signifies the liquor in which fish is pickled.

GAROU. See *Daphne gnidium*.

Garrophy'llus. See *Eugenia caryophyllata*.

Garroti'llo. (From *garottar*, to bind closely. Spanish.) A name of the cynanche maligna, from its sense of strangulation, as if the throat were bound with a cord.

GAS. (From *Gascht*, German, an eruption of wind.) *Gaz*. Elastic fluid; Aëriform fluid. This term is applied to all permanently elastic fluids, simple or compound, except the atmosphere, to which the term *air* is appropriated.

Some of the gases exist in nature without the aid of art, and may therefore be collected; others, on the contrary, are only producible by artificial means.

All gases are combinations of certain substances, reduced to the gaseous form by the addition of caloric. It is, therefore, necessary to distinguish in every gas, the matter of heat which acted the part of a solvent, and the substance which forms the basis of the gas.

Gases are not contained in those substances from which we obtain them in the state of gas, but owe their formation to the expansive property of caloric.

Formation of Gases.—The different forms under which bodies appear, depend upon a certain quantity of caloric, chemically combined with them. The very formation of gases corroborates this truth. Their production totally depends upon the combination of the particular substances with caloric; and though called permanently elastic, they are only so because we cannot so far reduce their temperature, as to dispose them to part with it; otherwise they would undoubtedly become fluid or solid.

Water, for instance, is a solid substance in all degrees below 32° of Fahrenheit's scale; above this temperature it combines with caloric, and it becomes a fluid. It retains its liquid state under the ordinary pressure of the atmosphere, till its temperature is augmented to 212°. It then combines with a larger portion of caloric, and is converted, *apparently*, into gas, or at least into elastic vapour; in which state it would continue, if the temperature of our atmosphere was above 212°. Gases are therefore solid substances, between the particles of which a repulsion is established by the quantity of caloric.

But as in the gaseous water or steam, the caloric is retained with but little force, on account of its quitting the water when the vapour is merely exposed to a lower temperature, we do not admit steam among the class of gases, or permanently elastic aëriform fluids. In gases, caloric united by a very forcible affinity, and no diminution of temperature, or increase of pressure, that has ever yet been effected, can separate it from them. Thus the air of our atmosphere, in the most intense cold, or when very strongly compressed, still remains in the aëriform state; and hence is derived the essential character of gases, namely, *that they shall remain aëriform, under all variations of pressure and temperature.*

In the modern nomenclature, the name of every substance existing in the aëriform state, is derived from its supposed solid base; and the term gas is used to denote its existence in this state.

In order to illustrate the formation of gases, or to show in what manner caloric is combined with them, the following experiment may serve. Put into a retort, capable of holding half a pint of water, two ounces of muriate of soda, (common salt:) pour on it half its weight of sulphuric acid, and apply the heat of a lamp; a great quantity of gas is produced, which might be collected and retained over mercury. But to serve the purpose of this experiment, let it pass through a glass receiver, having two openings, into one of which the neck of the retort passes, whilst, from the other, a bent tube proceeds, which ends in a vessel of water. Before closing the apparatus, let a thermometer be included in the receiver, to show the temperature of the gas. It will be found that the mercury in the thermometer will rise only a few degrees; whereas the water in the vessel which receives the bent tube, will soon become boiling hot.

Explanation.—Common salt consists of muriatic acid, united to soda; on presenting sulphuric acid to this union, a decomposition takes place, especially when assisted by heat. The sulphuric acid unites by virtue of its great affinity to the soda, and forms sulphate of soda, or Glauber's salt; the muriatic acid becomes therefore disengaged, and takes the gaseous form in which it is capable of existing at the common temperature. To trace the caloric during this experiment, as was our object, we must remark, that it first flows from the lamp to the disengaged, muriatic acid, and converts it into gas; but the heat thus expended is chemically united, and therefore not appreciable by the thermometer. The caloric, however, is again evolved, when the muriatic acid gas is condensed by the water, with which it forms liquid muriatic acid.

In this experiment we therefore trace caloric in a chemical combination producing gas; and from this union we again trace it in the condensation of the gas, producing sensible heat.

Such, in general, is the cause of the formation and fixation of gases. It may be further observed, that each of these fluids loses or suffers the disengagement of different quantities of heat, as it becomes more or less solid in its new combination, or as that combination is capable of retaining more or less specific heat.

The discovery of aëriform gaseous fluids has occasioned the necessity of some peculiar instruments, by means of which those substances may be conveniently collected and submitted to examination. The principal ones for that purpose are styled the *pneumatic apparatus.*

The *Pneumatic trough* is made either of wood or strong sheet iron, tinned, japanned, or painted. A trough of about two feet long, sixteen inches wide, and fifteen high, has been found to be sufficient for most experiments. Two or three inches below its brim, a horizontal shelf is fastened, in dimension about half or one-third part of the width of the trough. In this shelf are several holes: these holes must be made in the centre of a small excavation, shaped like a funnel, which is formed in the lower part of the shelf.

This trough is filled with water sufficient to cover the shelf to the height of an inch.

The use of this shelf is to support receivers, jars, or bell-glasses, which, being previously filled with water, are placed invertedly, their open end turned down upon the above-mentioned holes, through which the gases, conveyed there and directed by means of the funnel-shaped excavations, rise in the form of air bubbles into the receiver.

When the gaceous fluids are capable of being absorbed by water, as is the case with some of them, the trough must be filled with mercury. The price and gravity of this fluid make it an object of convenience and economy that the trough should be smaller than when water is used.

A mercurial trough is best cut in marble, freestone, or a solid block of wood. A trough about twelve inches long, three inches wide, and four deep, is sufficient for all private experiments.

Method of collecting Gases, and transferring them from one vessel to another.—If we are desirous of transmitting air from one vessel to another, it is necessary that the vessel destined to receive it be full of water, or some fluid heavier than air. For that purpose, take a wide-mouthed bell-glass, or receiver; plunge it under the water in the trough, in order to fill it; then raise it with the mouth downwards, and place it on the shelf of the trough, so as to cover one or more of the holes in it.

It will now be full of water, and continue so as long as the mouth remains below the surface of the fluid in the cistern; for, in this case, the water is sustained in the vessel by the pressure of the atmosphere, in the same manner as the mercury is sustained in the barometer. It may without difficulty be imagined, that if common air (or any other fluid resembling common air in lightness and elasticity) be suffered to enter the inverted vessel filled with water, it will rise to the upper part, on account of its levity, and the surface of the water will subside. To exemplify this, take a glass, or any other vessel, in that state which is usually called *empty*, and plunge it into the water with its mouth downwards: scarce any of it will enter the glass, because its entrance is opposed to the elasticity of the included air; but if the vessel be turned with its mouth upwards, it immediately fills, and the air rises in bubbles to the surface. Suppose this operation be performed under one of the jars or receivers, which are filled with water, and placed upon the perforated shelf, the air will ascend in bubbles as before, but, instead of escaping, it will be caught in the part of the jar, and expel part of the water it contains.

In this manner we see that air may be emptied out of one vessel into another by a kind of inverted pouring, by which means it is made to ascend from the lower to the upper vessel. When the receiving vessel has a narrow neck, the air may be poured, in a similar manner, through an inverted funnel, inserted in its mouth.

If the air is to be transferred from a vessel that is stopped like a bottle, the bottle must be unstopped, with its orifice downwards in the water; and then inclined in such a manner that its neck may come under the perforated excavation of the shelf. The gas will escape from the bottle, and passing into the vessel destined to receive it, will ascend in it in the form of bubbles.

In whatever manner this operation is performed, the necessity of the excavation in the lower part of the shelf may be readily conceived. It is, as mentioned before, destined to collect the gas which escapes from the vessel, and direct it in its passage towards the vessel adapted to receive it. Without this excavation, the gas, instead of proceeding to the place of its destination, would be dispersed and lost, unless the mouth of the receiving vessel were large.

The vessels, or receivers, for collecting the disengaged gases, should be glass cylinders, jars, or bell-glasses of various sizes; some of them should be open at both ends, others should be fitted with necks at the top, ground perfectly level, in order that they may be stopped by ground flat pieces of metal, glass, slate, &c.; others should be furnished with ground stoppers. Some should be graduated into cubic inches, and sub-divided into decimal or other equi-distant parts. Besides these common glass-bottles, tumblers, &c. may be used.

Classification of Gases.—All the elastic aëriform fluids with which we are hitherto acquainted, are generally divided, by systematic writers, into two classes; namely, those that are *respirable* and *capable of maintaining combustion*, and those that are *not respirable*, and *incapable of maintaining combustion*. This division, indeed, has its advantage, but the term respirable, in its physiological application, has been very differently employed by different writers. Sometimes by the respirability of a gas has been meant its power of supporting life, when repeatedly applied to the blood in the lungs. At other times all gases have been considered respirable which were capable of introduction into the lungs by voluntary efforts, without any relation to their vitality. In the last case, the word respirable seems to us most properly employed, and in this sense it is here used.

Non-respirable gases are those which, when applied to the external organs of respiration, stimulate the muscles of the epiglottis in such a manner as to keep it perfectly close on the glottis; thus preventing the smallest particle of gas from entering into the bronchia, in spite of voluntary exertions.

Of respirable gases, or those which are capable of being taken into the lungs by voluntary efforts, only one has the power of uniformly supporting life, namely, atmospheric air; other gases, when respired, sooner or later impair the health of the human constitution, or perhaps occasion death; but in different modes.

Some gases effect *no positive* change in the blood; animals immersed in it die of a disease produced by the privation of atmospheric air, analogous to that occasioned by their submersion in water.

Others again produce *some positive* change in the blood, as appears from the experiments of Dr. Beddoes and Sir Humphrey Davy. They seem to render it incapable of supplying the nervous and muscular fibres with principles essential to sensibility and irritability. These gases, therefore, destroy animal life on a different principle.

It is obvious, therefore, that the above classification is not very precise, but capable of misleading the student without proper explanation.

Gas, azotic. See *Nitrogen.*

Gas, carbonic acid. See *Carbonic acid.*

Gas, heavy corbonated hydrogen. See *Carburetted hydrogen gas.*

Gas, hepatic. See *Hydrogen gas, sulphuretted.*

Gas-hydrogen. See *Hydrogen.*

Gas, light carbonated hydrogen. See *Carburetted hydrogen gas.*

Gaseous oxide of carbon. See *Carbon, gaseous oxide of.*

GA'STRIC. (*Gastricus;* from γαςηρ, the stomach.) Appertaining to the stomach.

GASTRIC ARTERY. *Arteria gastrica.* The right or greater gastric artery, is a branch of the hepatic; the left, or lesser, a branch of the splenic.

GASTRIC JUICE. *Succus gastricus.* A fluid separated by the stomach. See *Digestion.*

GASTRINUM. Potassa.

GASTRI'TIS. (From γαςηρ, the stomach.) Inflammation of the stomach. A genus of disease in the class *Pyrexiæ*, and order *Phlegmasiæ* of Cullen. It is known by pyrexia, anxiety, heat, and pain in the epigastrium, increased when any thing is taken into the stomach, vomiting, hiccup, pulse small and hard, and prostration of strength. There are two species:

1. *Gastritis phlegmonodea*, with acute pain and severe fever.

2. *Gastritis erythematica*, when the pain and fever are slighter, with an erysipelatous redness appearing in the fauces.

Gastritis is produced by acrid substances of various kinds, such as arsenic, corrosive sublimate, &c. taken into the stomach, as likewise by food of an improper nature; by taking large draughts of any cold liquor when the body is much heated by exercise, or dancing; and by repelled exanthemata and gout. Besides these, it may arise from an inflammation of some of the neighbouring parts being communicated to the stomach.

The erysipelatous gastritis arises chiefly towards the close of other diseases, marking the certain approach to dissolution, and being unaccompanied with any marks of general inflammation, or by any burning pain in the stomach.

The symptoms of phlegmonous gastritis, as observed above, are a violent burning pain in the stomach, with great soreness, distention, and flatulency; a severe vomiting, especially after any thing is swallowed, whether it be liquid or solid; most distressing thirst; restlessness, anxiety, and a continual tossing of the body, with great debility, constant watching, and a frequent, hard, and contracted pulse. In some cases, a severe purging attends.

If the disease increases in violence, symptoms of irritation then ensue; there is a great loss of strength, with faintings; a short and interrupted respiration; cold, clammy sweats, hiccups, coldness of the extremities, an intermittent pulse, and the patient is soon cut off.

The event of gastritis is seldom favourable, as the person is usually either suddenly destroyed by the violence of the inflammation, or else it terminates in suppuration, ulceration, or gangrene.

If the symptoms are very mild, and proper remedies have been employed at an early period of the disease, it may, however, terminate in resolution, and that in the course of the first, or, at farthest, the second week.

Its termination in suppuration may be known by the symptoms, although moderate, exceeding the continuance of this period, and a remission of pain occurring, whilst a sense of weight and anxiety still remain; and, on the formation of an abscess, cold shiverings ensue, with marked exacerbations in the evening, which are followed by night sweats, and other symptoms of hectic fever; and these at length prove fatal, unless the pus is thrown up by vomiting, and the ulcer heals.

Its tendency to gangrene may be dreaded, from the violence of its symptoms not yielding to proper remedies early in the disease; and, when begun, it may be known by the sudden cessation of the pain; by the pulse continuing its frequency, but becoming weaker; and by delirium, with other marks of increasing debility ensuing.

Fatal cases of this disease show, on dissection, a considerable redness of the inner coat of the stomach, having a layer of coagulable lymph lining its surface. They likewise show a partial thickening of the substance of the organ, at the inflamed part, the inflammation seldom extending over the whole of it. Where ulceration has taken place, the ulcers sometimes are found to penetrate through all its coats, and sometimes only through one or two of them.

The cure is to be attempted by copious and repeated bleedings, employed at an early period of the disease, not regarding the smallness of the pulse, as it usually becomes softer and fuller after the operation: also, several leeches should be applied to the epigastrium, followed by fomentations or the hot bath; after which a large blister will be proper. The large intestines may be in some measure evacuated by a laxative clyster; but scarcely any internal medicine can be borne by the stomach, till the violence of the disease is much abated; we may then try magnesia, or other mild cathartic, to clear out the canal effectually. Where acrid substances have been taken, mucilaginous drinks may be freely exhibited, to assist their evacuation and sheathe the stomach; otherwise only in small quantity: and, in the former case, according to the nature of the poison, other chemical remedies may come in aid, but ought never to be too much relied upon. Should suppuration occur, little can be done beyond avoiding irritation, and supporting strength by a mild farinaceous diet, and giving opium occasionally to relieve pain.

GASTRO. Names compounded with this word, have some connexion with the stomach.

GASTROCE'LE. (From γαςηρ, the stomach, and κηλη, a tumour.) A hernia of the stomach, occasioned by a protrusion of that viscus through the abdominal parietes. See *Hernia ventriculi.*

GASTROCNE'MIUS. (From λαςηρ, the stomach, and κνημη, the leg.) The calf or belly of the leg.

GASTROCNEMIUS EXTERNUS. *Gemellus.* An extensor muscle of the foot, situated immediately under the integuments at the back part of the leg; sometimes called *gemellus*: this latter name is adopted by Albinus. Winslow describes it as two muscles, which he calls *gastrocnemii*; and Douglas considers this and the following as a *quadriceps*, or muscle with four heads, to which he gives the name of *extensor tarsi suralis.* It is called *bi femoro calcanien* by Dumas. The gastrocnemius externus arises by two distinct heads. The first, which is the thickest and longest of the two, springs by a strong thick tendon from the upper and back part of the inner condyle of the os femoris, adhering strongly to the capsular ligament of the joint, between which and the tendon is a considerable *bursa mucosa.* The second head arises by a thinner and shorter tendon from the back part of the outer condyle of the os femoris. A little below the joint, their fleshy bellies unite in a middle tendon, and below the middle of the tibia they cease to be fleshy, and terminate in a broad tendon, which, a little above the lower extremity of the tibia, unite with that of the gastrocnemius internus, to form one round tendon, sometimes called *chorda magna*, but commonly *tendo Achillis.*

GASTROCNEMIUS INTERNUS. *Tibio peronei calcanien* of Dumas. This, which is situated immediately under the last described muscle, is sometimes named *soleus*, on account of its shape, which resembles that of the sole-fish. It arises by two heads. The first springs by tendinous and fleshy fibres from the posterior part of the head of the fibula, and for some way below it. The second arises from an oblique ridge at the upper and posterior part of the tibia, which affords origin to the inferior edge of the popliteus, continuing to receive fleshy fibres from the inner edge of the tibia for some way down. This muscle, which is narrow at its origin, spreads wider, as it descends, as far as its middle; after which it becomes narrower again, and begins to grow tendinous, but its fleshy fibres do not entirely disappear till it has almost reached the extremity of the tibia, a little above which it unites with the last-described muscle, to form the *tendo Achillis.* This thick round chord is inserted into the lower and posterior part of the os calcis, after sliding over a cartilaginous surface on that bone, to which it is connected by a tendinous sheath that is furnished with a large *bursa mucosa.*

Both the gastrocnemii have the same use, viz. that of extending the foot by drawing it backwards and downwards.

GASTROCO'LIC. (*Gastrocolicus;* from γαϛηρ, the stomach, and κωλον, the colon.) A term applied to a vein which proceeds from the stomach to the colon.

GASTRODY'NIA. (From γαϛηρ, the stomach, and οδυνη, pain.) Pain in the stomach.

Gastro-epiploic artery. *Arteria gastrico-epiploica.* The branch of the greater gastric artery that runs to the epiploon.

GASTRORAPHY. (*Gastroraphe;* from γαϛηρ, the stomach, and ραφη, a suture.) The sewing of wounds of the abdomen.

GASTROTO'MIA. (From γαϛηρ, the belly, and τεμνω, to cut.) The operation of cutting open the belly.

GAU'BIUS, Jerome David, a celebrated Dutch physician, was a pupil of the illustrious Boerhaave at Leyden, where he graduated in 1725, and about 10 years after he became professor there, and taught with great applause for a period of forty years. His reputation was extended all over Europe by several valuable publications, particularly by his "Institutiones Pathologiæ Medicinalis," and his "Adversaria;" which contributed not a little to the improvement both of the theory and practice of medicine. In another work, he treated ably of the medical regulation of the mind: and he printed also a very elegant little book "De Methodo concinnandi formulas Medicamentorum." He died in 1780, in the 76th year of his age.

GAULE. See *Myrica gale.*

GAZ. (From *gascht,* a German word which means an eruption of wind.) See *Gas.*

GEHLENITE. A mineral substance allied to Vesuvian found along with calcareous spar in the Tyrol.

Geiso'ma. (From γεισον, the eaves of the house.) *Geison.* The prominent parts of the eye-brows, which hangs over the eyes like the eaves of a house.

Gei'son. See *Geisoma.*

Gela'sinos. (From γελαω, to laugh.) An epithet for the four middle fore-teeth, because they are shown in laughter.

Gela'smus. (From γελαω, to laugh.) The Sardonic laugh. See *Sardonic laugh.*

GE'LATIN. Gelly, or jelly. An animal substance soluble in water, but not in alkohol: capable of assuming a well-known elastic or tremulous consistence, by cooling, when the water is not too abundant, and liquifiable again, by increasing its temperature. This last property remarkably distinguishes it from albumen, which becomes consistent by heat. It is precipitated in an insoluble form by tannin, and it is this action of tannin on gelatin that is the foundation of the art of tanning leather.

Jellies are very common in our kitchens; they may be extracted from all the parts of animals, by boiling them in water. Hot water dissolves a large quantity of this substance. Acids likewise dissolve them, as do likewise more particularly the alkalies. Jelly, which has been extracted without long decoction, possesses most of the characters of vegetable mucilage; but it is seldom obtained without a mixture of albumen.

Jellies, in a pure state, have scarcely any smell or remarkable taste. By distillation, they afford an insipid and inodorous phlegm, which easily putrefies. A stronger heat causes them to swell up, become black, and emit a fœtid odour, accompanied with white acrid fumes. An impure volatile alkali, together with empyreumatic oil, then passes over, leaving a spongy coal, not easily burned, and containing common salt and phosphate of lime.

The jelly of various animal substances is prepared for the use of sea-faring persons under the name of portable soup. The whole art of performing this operation consists in boiling the meat, and taking the scum off, as usual, until the soup possesses the requisite flavour. It is then suffered to cool, in order that the fat may be separated. In the next place, it is mixed with five or six whites of eggs, and slightly boiled. This operation serves to clarify the liquid, by the removal of opaque particles, which unite with the white of egg at the time it becomes solid by the heat, and are consequently removed along with it. The liquor is then to be strained through flannel, and evaporated on the water-bath, to the consistence of a very thick paste; after which it is spread, rather thin, upon a smooth stone, then cut into cakes, and, lastly, dried in a stove, until it becomes brittle. These cakes may be kept four or five years, if defended from moisture. When intended to be used, nothing more is required to be done than to dissolve a sufficient quantity in boiling water, which by that means becomes converted into soup.

Jelly is also found in vegetables, as ripe currants, and other berries mixed with an acid.

GELA'TIO. (From *gelo,* to freeze.)

1. Freezing.
2. That rigidity of the body which happens in a catalepsy, as if the person were frozen.

GEM. This word is used to denote a stone which is considered as precious; as the diamond, ruby, sapphire, topaz, chrysolite, beryl, emerald, &c.

GEME'LLUS. (From *geminus,* double, having a fellow.) See *Gastrocnemius* and *Gemini.*

GEMINI. *Gemelli* of Winslow. Part of the *marsupialis* of Cowper. *Ischio spini trochanterien* of Dumas. A muscle of the thigh, which has been a subject of dispute among anatomists since the days of Vesalius. Some describe it as two distinct muscles; and hence the name it has gotten of *gemini.* Others contend that it ought to be considered as a single muscle. The truth is, that it consists of two portions, which are united together by a tendinous and fleshy membrane, and afford a passage between them to the tendon of the obdurator internus, which they inclose as it were in a purse. These two portions are placed under the glutæus maximus, between the ischium and the great trochanter.

The superior portion, which is the shortest and thickest of the two, arises fleshy from the external surface of the spine of the ischium; and the inferior, from the tuberosity of that bone, and likewise from the posterior sacro-ischiatic ligament. They are inserted, tendinous and fleshy, into the cavity at the root of the great trochanter. Between the two portions of this muscle, and the termination of the obturator internus, there is a small *bursa mucosa*, connected to both, and to that part of the capsular ligament of the joint which lies under the gemini.

This muscle assists in rolling the os femoris outwards, and prevents the tendon of the obturator internus from slipping out of its place while that muscle is in action.

GEMMA. 1. A precious stone or gem.

2. In botany this term is now applied exclusively to the buds on the stems of plants. The ancients used the terms *germen* and *oculus* to denote those buds which contain the rudiments of branches and leaves, and *gemma* those in which flowers only are contained; but by the moderns, *germen* has been applied to denote the rudiment of the fruit, or as a generic term for all buds.—*Thompson.*

A *gemma* or bud contains the rudiments of a plant, or of part of a plant, for a while in a latent state, till the time of the year, and other circumstances, favour their evolution. In the bud, therefore, the vital principle is dormant. Buds of trees or shrubs, destined for cold countries, are formed in the course of the summer in the bosoms of their leaves, and are generally solitary; but in the *Lonicera cærulea*, or blue-berried honey-suckle, they grow one under another for three successive seasons.

The buds of the plane tree, *Platanus*, are concealed in the footstalk, which must be removed before they can be seen, and which they force off by their increase; so that no plant can have more truly and necessarily deciduous leaves.

Shrubs in general have no buds, neither have the trees of hot climates.

Buds are various in their forms, but very uniform in the same species, or even genus. They consist of scales closely enveloping each other, and enfolding the embryo plant or branch. Externally they have often an additional guard of gum, resin, or woolliness, against wet or cold. The horse-chesnut affords a fine example of large and well-formed buds.

The contents of buds are different, even in different species of the same genus, as willows. The buds of some produce leaves only, others flowers, while in other species the same bud bears both leaves and flowers. Different causes, depending on the soil or situation, seem in one case to generate leaf-buds, in another flower-buds. In general, whatever checks the luxuriant production of leaf-buds, favours the formation of flowers and seeds.—*Smith.*

Gems are found in all trees and shrubs in temperate climates. In the majority of instances they are visible from the first, in which case they are *axillary*, that is, seated in the axillæ of the leaves, or the angle which the upper part of the footstalk of the leaf makes with the surface of the stem; but in some instances, as the sumachs and planes, they are *latent*, being hid within the base of the footstalk, and never seen until the fall of the leaf. Gems are however sometimes protruded from the trunk, long after it has ceased to produce leaves, as in the case of adventitious buds; they are also situated on roots, and on tubers, but in these cases they are usually denominated *oculi*, or *eyes*.

Annual plants are supposed to be furnished with gems; but although they are devoid of covered gems, yet their lateral shoots proceed from naked buds which immediately spread into foliage.

The relative position of *axillary* gems is necessarily regulated by that of the leaf, and therefore we find them,

1. *Opposite*, or placed exactly on the same line on opposite sides of the stem or the branch.
2. *Alternate*, or placed alternately, although on opposite sides; and,
3. *Spiral*, that is placed round the stem or branch in such a manner that a cord wound in a spiral manner round it would touch each gem.

They are said to be *simple* or *solitary*, when one gem only is seen in the axilla of each leaf, as in the greater number of instances; and *aggregate*, when, as in some plants, two, three, or even more are protruded at the same time: thus we find two in the *Sambucus nigra*, or common elder; three in the *Aristolochia sipho*, or broad-leaved birth-wort; and many in the *Zanthoxylum fraxineum*, or toothache tree.

Du Hamel first noticed the fact, that stems and branches furnished with alternate axillary gems have generally one *terminal* gem only; and those with opposite have generally three terminal gems.

The gems on most trees and shrubs rise with a broad base from the furface where they are protruded, and consequently being in close contact with it, are said to be *sessile*; but they are distant or stalked on some, as the common alder, on which they are supported on a short footstalk, and are termed *pedicillatæ* or stalked.

Gems differ very considerably in the number and characters of the enclosing scales, their contents, the folding up of the leaves within them, and the manner in which they are evolved in the spring.

a. The scales differ in size and texture, even in the same gem: in the gems of different plants, they differ also in number and in the nature of their coverings; some gems are entirely destitute of scales; as those of annual plants, and many perennials of tropical climates. The scales in some instances are besmeared with a resinous matter; in others they are entirely free from any moist exudation, but are smooth and polished, being covered with a dry gummy varnish; or they are externally hairy or enveloped in a velvety down.

Gems are arranged into three species:

1. *Gemmæ foliiferæ*, leaf gems.
2. *Gemmæ floriferæ*, flower gems.
3. *Gemmæ mixtæ*, mixed gems.

The *Amygdalus persica*, or peach-tree, the *Daphne mezereum*, and many other plants, afford examples of distinct leaf and flower gems; the *Syringa vulgaris* and *Æsculus hippocastanum*, of mixed gems; and the pear and apple-trees of both leaf and mixed gems.

The leaves, as has already been mentioned, are variously folded up so as to occupy the smallest possible space in the gem. This regulates the expansion of the leaves when the gem opens in spring, and it is invariably the same in individual plants of the same species. This process is termed *foliation*, and the figures which the leaves assume at the time have received different appellations.—*Thompson.*

1. *Foliatio involuta*, involute, in which each internal margin of the leaf is rolled inwards; as in *Humulus lupulus* and *Nymphæ lutea.*

2. *F. revoluta*, revolute, in which the lateral margins are rolled outwards; as in willows, and *Rumex patientia.*

3. *F. obvoluta*, obvolute, in which one leaf, doubled length ways, embraces within its doubling one-half of the other leaf, folded in the same manner; as in *Sulvia officinalis*, and *Dipsacus communis*.

4. *F. convoluta*, convolute, in which the leaf is rolled length-ways in a spiral manner, one margin forming the axis round which the other turns; as in *Prunus domestica*, and *Prunus armeniaca*, the cabbage, grasses, &c.

5. *F. equitans*, equitant, in which the leaf is so folded that the two sides deeply embrace the opposite leaf, which in its turn encloses the one opposed to it, and so on to the centre of the bud; this is beautifully exemplified in the *Hemarocallis*, or day-lily, and *Syringa vulgaris*.

6. *F. conduplicata*, in which the two sides of the leaf lie parallel to each other; as in *Fagus sylvatica*, and *Quercus robur*.

7. *F. plicata*, plaited, the leaf being folded up like a fan; as in *Betula alba*, and *Alchemilla vulgaris*.

8. *F. reclinata*, reclinate, turned down, the leaf hanging down and wrapt round the footstalk; as in *Aconitum* and *Arum*.

9. *F. circinata*, circinal, in which the leaf is rolled from the apex to the base; as in all ferns.

As the gems open, the leaves gradually unfold themselves, and assume their natural forms; but the opening of the bud does not in every instance immediately set free the leaves, for in some gems each leaf is separately enclosed in a membraneous cover.

GEMMACEUS. A term used by botanists to a flower-stalk which grows out of a leaf-bud, as is seen in the *Berberis vulgaris*.

GEMMATIO. (From *gemma*, a bud.) A term used by Linnæus expressive of the origin, form, &c. of buds.

Gemu'rsa. (From *gemo*, to groan: so called from the pain it was said to occasion in walking.) The name of an excrescence between the toes.

Genei'as. (From γενυς, the cheek.)

1. The downy hairs which first cover the cheek.

2. The name of a bandage mentioned by Galen, which covers the cheek, and comes under the chin.

GENERATION. (*Generatio;* from γεινομαι, to beget.) Many ingenious hypotheses have been instituted by physiologists to explain the mystery of generation: but the whole of our knowledge concerning it appears to be built upon the phenomena it affords, and may be seen in the works of Haller, Buffon, Cruickshanks, and Haighton. It is a sexual action, performed in different ways in most animals; many of them have different sexes, and require conjunction: such are the human species, quadrupeds, and others. The females of quadrupeds have a matrix, separated into two cavities, *uterus bicornis*, and a considerable number of teats; they have no menstrual flux; most of them bear several young at a time, and the period of their gestation is generally short. The generation of birds is very different. The males have a strong genital organ, which is often double. The vulva in the females is placed behind the anus; the ovaries have no matrices, and there is a duct for the purpose of conveying the egg from the ovarium into the intestines; this passage is called the oviduct. The eggs of pullets have exhibited unexpected facts to physiologists, who examined the phenomena of incubation. The most important discoveries are those of the immortal Haller, who found the chicken perfectly formed in eggs which were not fecundated. There is no determinate conjunction between fishes; the female deposits her eggs on the sands, over which the male passes, and emits its seminal fluid, doubtless for the purpose of fecundating them; these eggs are hatched after a certain time. The males of several oviparious quadrupeds have a double or forked organ. Insects exhibit all the varieties which are observed in other animals: there are some, indeed the greater number, which have the sexes in two separate individuals; among others, the reproduction is made either with or without conjunction, as in the wine-fretter; one of these insects, confined alone beneath a glass, produces a great number of others. The organ of the male in insects is usually armed with two hooks to seize the female: the place of these organs is greatly varied; with some, it is at the upper part of the belly, near the chest, as in the female dragon-fly; in others, it is at the extremity of the *antenna*, as in the male spider. Most worms are hermaphrodite; each individual has both sexes. Polypi, with respect to generation, are singular animals; they are reproduced by buds or offsets; a bud is separated from each vigorous polypus, which is fixed to some neighbouring body, and grows: polypi are likewise found on their surface, in the same manner as branches issue from plants. These are the principal modes of generation in animals. In the human species, which engages our attention more particularly, the phenomena are as follow:

The part of the male, in the act of reproduction, is to deposit the semen in the vagina at a greater or less distance from the orifice of the uterus.

The function which the female discharges is much more obscure; some feel, at this moment, very strong voluptuous sensations; others appear entirely insensible; whilst others, again, experience a sensation which is very painful. Some of them pour out a mucous substance in considerable abundance, at the instant of the most vivid pleasure: whilst, in the greater part, this phenomenon is entirely wanting. In all these respects, there is, perhaps, no exact resemblance between any two females.

These different phenomena are common to the most frequent acts of copulation, that is, to those which do not produce impregnation, as well as those which are effective.

The most recent opinion is, that the uterus during impregnation opens a little, draws in the semen by aspiration, and directs it to the ovarium by means of the Fallopian tubes, the fimbriated extremity of which closely embraces that organ.

The contact of the semen determines the rupture of one of the vesicles, and the fluid that passes from it, or the vesicle itself, passes into the uterus, where the new individual is to be developed.

However satisfactory this explanation may appear, it is purely hypothetical, and even contrary to the experiments of the most exact observers.

In the numerous attempts made upon animals by Harvey, DeGraaf, Valisneri, &c., the semen has never been perceived in the cavity of the uterus; much less has it been seen in the Fallopian tube at the surface of the ovarium. It is quite the same with the motion which the Fallopian tube is supposed to have in embracing the circumference of the ovarium: it has never been proved by experiment. Even if one should suppose that the semen penetrates into the uterus at the moment of coition, which is not impossible, though it has not been observed, it would still be very difficult to comprehend how the fluid could pass into the Fallopian tubes, and arrive at the ovarium. The uterus in the empty state is not contractible; the uterine orifice of the Fallopian tubes is extremely narrow, and these canals have no known sensible motion.

On account of the difficulty of conceiving the passage of the semen to the ovarium, some authors have imagined that this matter is not carried there, but only the vapour which exhales from it, or the *aura seminalis*. Others think that the semen is absorbed in the vagina, passes into the venous system, and arrives at the ovaria by the arteries. The phenomena which accompany the fecundation of women are, then, nearly unknown. An equal obscurity rests on the fecundation of other mammiferous females. Nevertheless, it would be more easy to conceive a passage of the semen to the ovaria in these, since the uterus and the Fallopian tubes possess a peristaltic motion like that of the intestines. Fecundation, however, taking place by the contact of the semen with the ova, in fishes, reptiles and birds, it is not very likely that nature employs any other mode for the *mammifera*; it is necessary, then, to consider it as very probable that, either at the instant of coition, or at a greater or less time afterwards, the semen arrives at the ovarium, where it exerts more especially its action upon the vessels most developed.

But, even should it be out of doubt that the semen arrives at the vesicles of the ovarium, it would still remain to be known how its contact animates the germ contained in it. Now, this phenomenon is one of those on which our senses, and even our mind, have no hold: it is one of those impenetrable mysteries of which we are, and, perhaps, shall ever remain ignorant.

We have, however, on this subject some very ingenious experiments of Spallanzani, which have removed the difficulty as far as it seems possible. This philosopher has proved by a great number of trials, 1st, that three grains of semen, dissolved in two pounds of water, are sufficient to give to it the fecundating virtue; 2d, that the spermatic animalcula are not necessary to fecundation, as Buffon and other authors have thought; 3d, that the *aura seminalis*, or seminal vapour, has no fecundating property; 4th, that a bitch can be impregnated by the mechanical injection of semen into her vagina, &c. &c.

It is thus necessary to consider as conjectural what authors say about the general signs of fecundation. At the instance of conception, the woman feels, it is said, a universal tremor, continued for some time, accompanied by a voluptuous sensation; the features are discomposed, the eyes lose their brilliancy, the pupils are dilated, the visage pale, &c. No doubt, impregnation is sometimes accompanied by these signs; but many mothers have never felt them, and reach even the third month of their pregnancy without suspecting their situation."—*Magendie's Physiology.*

Fecundation having thus taken place, a motion is induced in the vivified ovum, which ruptures the tender vesicle that contains it; the fimbriæ of the Fallopian tube then grasp and convey it into the tube, which, by its peristaltic motion, conducts it into the cavity of the uterus, there to be evolved and brought to maturity, and, at the expiration of nine months, to be sent into the world.

Generation, organs of. The parts subservient to generation in a woman are divided into external and internal. The external parts are the *mons veneris*, the *labia*, the *perinæum*, the *clitoris*, and the *nymphæ*. To these may be added the *meatus urinarius*, or orifice of the urethra. The *hymen* may be esteemed the barrier between the external and internal parts. The internal parts of generation are the *vagina* and *uterus*, and its appendages.

The parts which constitute the organs of generation in men, are the *penis*, *testes*, and *vesiculæ seminales*.

GENICULATUS. Geniculate; bent like the knee: applied to the culm or straw of grasses; as in *Alopecuris geniculatus*.

GENIO. (From γενειον, the chin.) Names compounded of this word belong to muscles which are attached to the chin.

Genio-hyo-glossus. (From γενειον, the chin, νοειδές, the os hyoides, and γλωσσα, the tongue; so called from its origin and insertion.) *Genio glossus* of some authors. The muscle which forms the fourth layer between the lower jaw and os hyoides. It arises from a rough protuberance in the inside of the middle of the lower jaw; its fibres run like a fan, forwards, upwards, and backwards, and are inserted into the tip, middle, and root of the tongue, and base of the os hyoides, near its corner. Its use is to draw the tip of the tongue backwards into the mouth, the middle downwards, and to render its back concave. It also draws its root and the os hyoides forwards, and thrusts the tongue out of the mouth.

Genio-hyoideus. (From γενειον, the chin, and νοειδες, the os hyoides; so called from its origin in the chin, and its insertion in the os hyoides.) The muscle which constitutes the third layer between the lower jaw and os hyoides. It is a long, thin, and fleshy muscle, arising tendinous from a rough protuberance at the inside of the chin, and growing somewhat broader and thicker as it descends backward to be inserted by very short tendinous fibres into both the edges of the base of the os hyoides. It draws the os hyoides forwards to the chin.

Geniopharynge'us. See *Constrictor pharyngis superior.*

GE'NIPI. A term of barbarous origin applied to two plants.

Genipi album. See *Artemisia rupestris.*

Genipi verum. The plant directed for medicinal purposes under this title, is the *Achillea—foliis pinnatis, pinnis simplicibus, glabris, punctatis*, of Haller. It has a very grateful smell, and a very bitter taste, and is exhibited in Switzerland, in epilepsy, diarrhœa, and debility of the stomach.

GENI'STA. (From *genu*, a knee; so called from the inflection and angularity of its twigs.) 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria*.

2. The pharmacopœial name of the common broom. See *Spartium scoparium*.

Genista canariensis. This tree was supposed to afford the lignum Rhodium, which is now known to be an aspalathus. See *Aspalathus canariensis*.

Genista spinosa indica. *Bahel schulli.* An Indian tree, a decoction of the roots of which is diuretic. The leaves, boiled and sprinkled in vinegar, have the same effect, according to Ray.

Genista tinctoria. The systematic name of *Chamæpartium*, or Dyer's broom.

GENITA'LE. (From *gigno*, to beget.) The membrum virile. See *Penis*.

Genita'lium. (From *genitale*, the membrum virile.) A disease of the genital parts.

GENITICA. (From γεινομαι, *gignor*.) The name of a class of diseases, in Good's Nosology, embracing diseases of the sexual function. It has three orders, viz. *Cenotica Orgastica*; *Carpotica*.

GENITU′RA. (From *gigno.*) 1. The male seed.

2. The membrum virile.

GE′NON. (From γονυ, the knee.) A moveable articulation like that of the knee.

GENSING. See *Panax.*

GENTIA′NA. (From *Gentius*, king of Illyria, who first used it.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Digynia.* Gentian.

2. The pharmacopœial name of the gentian root. See *Gentiana lutea.*

GENTIANA ALBA. See *Laserpitium latifolium.*

GENTIANA CENTAURIUM. Lesser centaury was so called in the Linnæan system; but it is now *Chironia centaurium.*

GENTIANA LUTEA. The systematic name of the officinal gentian. *Gentiana rubra.* Felwort. The gentian met with in the shops, is the root of the *Gentiana—corollis subquinquefidis rotatis verticillatis, calycibus spathaceis,* of Linnæus; and is imported from Switzerland and Germany. It is the only medicinal part of the plant, has little or no smell, but to the taste manifests great bitterness, on which account it is in general use as a tonic, stomachic, anthelmintic, antiseptic, emmenagogue, and febrifuge. The officinal preparations of this root are the *infusum gentianæ compositum,* and *tinctura gentianæ composita,* of the London Pharmacopœia, and the *infusum amarum, vinum amarum, tinctura amara,* of the Edinburgh Pharmacopœia; and the *extractum gentianæ* is ordered by both.

GENTIANA RUBRA. See *Gentiana lutea.*

Gentianine. The bitter principle of the Gentian root.

GE′NU. The knee.

GENU′GRA. (From γονυ, the knee, and αγρα, a seizure.) A name in Paracelsus for the gout in the knee.

GENUS. (From γενος, a family.) By this term is understood, in natural history, a certain analogy of a number of species, making them agree together in the number, figure, and situation of their parts; in such a manner, that they are easily distinguished from the species of any other genus, at least by some one article. This is the proper and determinate sense of the word genus, whereby it forms a sub division of any class, or order of natural beings, whether of the animal, vegetable, or mineral kingdoms, all agreeing in certain common and distinct characters.

GEODES. A kind of ætites, the hollow of which contains only loose earth, instead of a nodule.

GEOFFRÆ′A. (Named in honour of Dr. Geoffroy.) *Geoffroya.* 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia;* Order, *Decandria.*

2. The pharmacopœial name of the cabbage bark-tree. See *Geoffræa inermis.*

GEOFFRÆA INERMIS. The systematic name of the cabbage bark-tree, or worm bark-tree. *Geoffræa—foliis lanceolatis of* Swartz. It has a mucilaginous and sweetish taste, and a disagreeable smell. According to Dr. Wright of Jamaica, it is powerfully medicinal as an anthelmintic.

GEOFFRÆA JAMAICENSIS. The systematic name of the bastard cabbage tree, or bulge-water tree. *Geoffroya—inermis foliolis lanceolatis,* of Swartz. The bark is principally used in Jamaica, and with great success, as a vermifuge.

GEOFFRÆA SURINAMENSIS. The systematic name of a tree, the bark of which is esteemed as an anthelmintic.

GEOFFROY, STEPHEN FRANCIS, was born at Paris, in 1672. After giving him an excellent general education, his father, who was an apothecary, sent him to study his own profession at Montpelier; where he attended the several lectures. On his return to Paris, having already acquired considerable reputation, he was appointed to attend the Duke de Tallard, on his embassy to England, in 1698. Here he was very favourably received, and elected a member of the Royal Society: and he afterwards visited Holland and Italy. His attention was chiefly directed to natural history and the materia medica, his father wishing him to succeed to his establishment at Paris: however he became ambitious of the higher branch of the profession, and at length graduated in 1704. His reputation rapidly increased; and he was called in consultation even by the most distinguished practitioners. In 1709 he was appointed to the professorship of medicine on the death of Tournefort. He then undertook to deliver to his pupils a complete History of the Materia Medica, divided into mineral, vegetable, and animal substances; the first part of which he finished, and about half of the second: this was afterwards published from his papers, in Latin, in three octavo volumes. In 1712 he was made professor of chemistry in the king's garden; and 14 years after, dean of the faculty. In this office he was led into some active disputes; whence his health, naturally delicate, began to decline; and he died in the beginning of 1731. Notwithstanding his illness, however, he completed a work, which had been deemed necessary by preceding deans, but never accomplished; namely, a Pharmacopœia, which was published under the name of "Codè Medicamentaire de la Faculté de Paris."

GEOGNOSY. The same as geology.

GEOLOGY. (*Geologia;* from γη, the earth, and λογος, a discourse.) A description of the structure of the earth. This study may be divided, like most others, into two parts; observation and theory. By the first we learn the relative positions of the great rocky or mineral aggregates that compose the crust of our globe; through the second, we endeavour to penetrate into the causes of these collocations. A valuable work was some time since published, comprehending a view of both parts of the subject, by Mr. Greenough, to which the reader is referred for much instruction, communicated in a very lively manner.

Very recently the world has been favoured with the first part of an excellent view of this science by Messrs. Conybeare and Phillips, in their "Outlines of the Geology of England and Wales;" from which work, the following brief sketch of the subject is taken: The *Traité de Geognosie* of D'Aubuisson bears a high character on the continent.

WERNER'S *Table of the different Mountain Rocks, from Jameson.*

CLASS I.

Primitive rocks.

1. Granite.
2. Gneiss.
3. Mica-slate.
4. Clay-slate.
5. Primitive limestone.
6. Primitive trap.
7. Serpentine.
8. Porphyry.
9. Syenite.
10. Topaz-rock.
11. Quartz-rock.
12. Primitive flinty-slate.
13. Primitive gypsum.
14. White stone.

CLASS II.

Transition rocks.

1. Transition limestone.
2. Transition trap.
3. Greywacke.

4. Transition flinty-slate.
5. Transition gypsum.

Class III.
Floetz rocks.

1. Old red sandstone, or first sandstone formation.
2. First or oldest floetz limestone.
3. First or oldest floetz gypsum.
4. Second or variegated sandstone formation.
5. Second floetz gypsum.
6. Second floetz limestone.
7. Third floetz limestone.
8. Rock-salt formation.
9. Chalk formation.
10. Floetz-trap formation.
11. Independent coal formation.
12. Newest floetz-trap formation.

Class IV.
Alluvial rocks.

1. Peat.
2. Sand and gravel.
3. Loam.
4. Bog-iron ore.
5. Nagelfluh.
6. Calc-tuff.
7. Calc-sinter.

Class V.
Volcanic rocks.

Pseudo-volcanic rocks.

1. Burnt clay.
2. Porcelain jasper.
3. Earth slag.
4. Columnar clay ironstone.
5. Polier, or polishing slate.

True volcanic rocks.

1. Ejected stones and ashes.
2. Different kinds of lava.
3. The matter of muddy eruptions.

The primitive rocks lie undermost, and never contain any traces of organized beings imbedded in them. The transition rocks contain comparatively few organic remains, and approach more nearly to the chemical structure of the primitive, than the mechanical of the secondary rocks. As these transition rocks were taken by Werner from among those which in his general arrangement were called secondary, the formation of that class made it necessary to abandon the latter term. To denote the mineral masses reposing in his transition series, he accordingly employed the term floetz rocks, from the idea that they were generally stratified in planes nearly horizontal, while those of the older strata were inclined to the horizon at considerable angles. But this holds good with regard to the structure of those countries only which are comparatively low; in the Jura chain, and on the borders of the Alps and Pyrenees, Werner's floetz formations are highly inclined. Should we therefore persist in the use of this term, says Mr. Conybeare, we must prepare ourselves to speak of vertical beds of floetz, (*i. e.* horizontal,) limestone, &c. As the inquiries of geologists extended the knowledge of the various formations, Werner, or his disciples, found it necessary to subdivide the bulky class of floetz rocks into floetz and newest floetz, thus completing a fourfold enumeration. Some writers have bestowed the term *tertiary* on the newest floetz rocks of Werner. The following synoptical view of geological arrangement is given by the Rev. Mr. Conybeare.

CHARACTER.	PROPOSED NAMES.	WERNERIAN NAMES.	OTHER WRITERS.
1. Formations (chiefly of *sand* and *clay*) above the chalk.	*Superior order.*	Newest floetz class.	Tertiary class.
2. Comprising, a. Chalk. b. Sands and clays, *beneath the chalk.* c. Calcareous freestones (*oolites*) and argillaceous beds. d. *New red sandstone, conglomerate, and magnesian limestone.*	*Supermedial order.*	Floetz class.	Secondary class.
3. Carboniferous rocks, comprising, a. *Coal measures.* b. *Carboniferous limestone.* c. *Old red sandstone.*	*Medial order.*	Sometimes referred to the preceding, sometimes to the succeeding class, by writers of these schools; very often the coal measures are referred to the former, the subjacent limestone and sandstone to the latter.	
4. *Roofing slate, &c. &c.*	*Submedial order.*	Transition class.	Intermediate class.
5. *Mica slate, gneiss, granite, &c.*	*Inferior order.*	Primitive class.	Primitive class.

In all these formations, from the lowest to the highest, we find a repetition of rocks and beds of similar chemical composition; *i. e.* siliceous, argillaceous, and calcareous, but with a considerable difference in texture; those in the lowest formations being compact and often crystalline, while those in the highest and most recent are loose and earthy. These repetitions form what the Wernerians call formation suites. We may mention,

1*st.* The *limestone suite.* This exhibits in the inferior or primitive order, crystalline marbles; in the two next, or transition and carboniferous orders, compact and subcrystalline limestones (Derbyshire limestone;) in the supermedial or floetz order, less compact limestone (lias,) calcareous freestone (Portland and Bath stone,) and chalk; in the superior or newest floetz order, loose earthy limestones.

2*d.* The *argillaceous suite* presents the following gradations; clay-slate, shale of the coal-measures, shale of the lias, clays alternating in the oolite series, and that of the sand beneath the chalk; and, lastly, clays above the chalk.

3*d.* The *silicious suite* may (since many of the sandstones of which it consists present evident traces of felspar and abundance of mica, as well as grains of quartz, and since mica is more or less present in every bed of sand) perhaps deserves to have granite placed at its head, as its several members may possibly have been derived from the detritus of that rock: it may be continued thus; quartz rock and transition sandstone, old red sandstone, millstone-grit, and coal-grits, new red sandstone, sand and sandstone beneath the chalk, and above the chalk. In all these instances a regular diminution in the degree of consolidation may be perceived in ascending the series.

GERA′NIS. (From γερανος, a crane: so called from its supposed resemblance to an extended crane.) A bandage for a fractured clavicle.

GERA′NIUM. (From γερανος, a crane: so called because its pistil is long like the bill of a crane.) Class, *Monadelphia;* Order, *Decandria.* The name of a genus of plants in the Linnæan system. Geranium, or cranes-bill.

GERANIUM BATRACHIOIDES. See *Geranium pratense.*

GERANIUM COLUMBINUM. See *Geranium rotundifolium.*

GERANIUM MOSCHATUM. The adstringent property of this plant has induced practitioners to exhibit it in cases of debility and profluvia.

GERANIUM PRATENSE. The systematic name of the crow foot crane's-bill. *Geranium batrachioides.* A plant which possesses adstringent virtues, but in a slight degree.

GERANIUM ROBERTIANUM. Stinking cranes-bill. Herb Robert. This common plant has been much esteemed as an external application in erysipelatous inflammations, cancer, mastodynia, and old ulcers, but is now deservedly fallen into disuse.

GERANIUM ROTUNDIFOLIUM. The systematic name of the doves-foot. *Geranium columbinum.* This plant is slightly astringent.

GERANIUM SANGUINARIUM. See *Geranium sanguineum.*

GERANIUM SANGUINEUM. The systematic name of the *Geranium sanguinarium.* Bloody crane's bill. The adstringent virtues acribed to this plant do not appear to be considerable.

GERM. See *Corculum.*

GERMANDER. See *Teucrium chamædrys.*

Germander water. See *Teucrium Scordium.*

GERMEN. This is the rudiment of the young fruit and seed, and is found at the bottom of the pistil. See *Pistillum.* It appears under a variety of shapes and sizes.

From its figure it is called,

1. *Globose;* as in *Rosa eglantaria,* and *cinnamomea.*

2. *Oblong;* as in *Stellaria biflora.*

3. *Ovate;* as in *Rosa canina,* and *alba.*

From its situation, it is distinguished into,

1. *Superior,* when internal between the corolla; as in *Prunus.*

2. *Inferior,* below and without the corolla; as in *Galanthus nivalis.*

3. *Pedicellate,* upon a footstalk; as in the *Euphorbia.*

It is of great moment for botanical distinctions, to observe whether it be superior, above the bases of the calyx, or below.

GERMINATION. *Germinatio.* The vital development of a seed, when it first begins to grow.

GEROCO′MIA. (From γερὼν, an aged person, and κομεω, to be concerned about.) That part of medicine which regards the regimen and treatment of old age.

GERONTOPO′GON. (From γερων, an old man, and πωγὼν, a beard; so called because its downy seed, while enclosed in the calyx, resembles the beard of an aged man.) The herb old man's beard, a species of tragopogon.

GERONTO′XON. (From γερων, an old person, and τοξον, a dart.) 1. A small ulcer, like the head of a dart, appearing sometimes in the cornea of old persons.

2. The socket of a tooth.

GEROPO′GON. See *Gerontopogon.*

GE′RYON. Quicksilver.

GESNER, CONRAD, was born at Zurich, in 1516. His father was killed in the civil war, and left him in such poverty, that he was obliged to become a servant at Strasburg. His master allowed him to devote some time to study, in which he made great progress; and having acquired a little money, he went to Paris, where he improved rapidly in the classics and rhetoric, and then turned his attention to philosophy and medicine. But he was soon compelled to return to his native country, and teach the languages, &c. for a livelihood. This enabled him afterwards to resume his medical studies at Montpelier, and he graduated at Basil in 1540. He then settled in his native city, where he was appointed professor of philosophy, which office he discharged with great reputation for twenty-four years. He had an early predilection for botany, which led him to cultivate other parts of natural history; he was the first collector of a museum, and acquired the character of being the greatest naturalist since Aristotle. He also founded and supported a botanic garden, had numerous drawings and wood engravings made of plants, and appears to have meditated a general work on that subject. He likewise discovered the only true principles of botanical arrangement in the flower and fruit. Though of a feeble and sickly constitution, he traversed the Alps, and even sometimes plunged into the waters in search of plants; he also carefully studied their medical properties, and frequently hazarded his life by experiments on himself; indeed he was at one time reported to have been killed by the root of doronicum. His other occupations prevented his entering very extensively into practice, but his enlarged views rendered him successful; and the profits of his profession enabled him to support the great expense of his favourite pursuits. He gave also many proofs of liberal and active friendship. He died of the plague, in 1565. His chief works are his "Historiæ Animalium," in three folio volumes, with wood cuts; and a pharmacopœia, entitled "De Secretis Remediis Thesaurus," which passed through many editions.

Gestation, uterine. See *Pregnancy.*

GE′UM. 1. The name of a genus of plants in the Linnæan system. Class, *Icosandria;* Order, *Polygynia.*

2. The pharmacopœial name of the two following species of this genus.

GEUM RIVALE. The root is the part directed for medicinal uses. It is inodorous, and imparts an austere taste. In America it is in high estimation in the cure of intermittents, and is said to be more efficacious than the Peruvian bark. Diarrhœas and hæmorrhages are also stopped by its exhibition.

GEUM URBANUM. The systematic name of the herb bennet, or avens. *Caryophyllata; Herba benedicta; Caryophyllus vulgaris; Garyophilla; Janamunda; Geum—floribus erectis, fructibus globosis villosis, aristis uncinatis, nudis, foliis lyratis,* of Linnæus. The root of this plant has been employed as a gentle styptic, corroborant, and stomachic. It has a mildly austere, somewhat aromatic taste, and a very pleasant smell, of the clove kind. It is also esteemed on the Continent as a febrifuge.

GIBBUS. Gibbous; swelled; applied to leaves when swelled on one side or both, from excessive abundance of pulp; as in the *Aloe retusa.*

GIDDINESS. See *Vertigo.*

GILBERT, William, was born at Colchester in 1540. After studying at Cambridge, he went abroad for improvement, and graduated at some foreign university. He returned with a high character for philosophical and chemical knowledge, and was admitted into the college of physicians in London, where he settled about the year 1573. He was so successful in his practice, that he was at length made first physician to Queen Elizabeth, who allowed him a pension to prosecute philosophical experiments. He died in 1603, leaving his books, apparatus, and minerals to the college of physicians. His capital work on the magnet was published three years before his death; it is not only the earliest complete system on that subject, but also one of the first specimens of philosophy founded upon experiments; which method the great Lord Bacon afterwards so strenuously recommended.

Gilead, balsam. See *Amyris gileadensis.*

GILLIFLOWER. See *Dianthus caryophyllus.*

GIN. *Spiritus Juniperi.* Geneva. Hollands. The names of a spirit distilled from malt or rye, which afterwards undergoes the same process, a second time, with juniper-berries. This is the original and most wholesome state of the spirit; but it is now prepared without juniper-berries, and is distilled from turpentine, which gives it something of a similar flavour. The consumption of this article, especially in the metropolis, is immense, and the consequences are pernicious to the health of the inhabitants.

GINGER. See *Zingiber.*

GI'NGIBER. See *Zingiber.*

Gingibra'chium. (From *gingivæ*, the gums, and *brachium*, the arm.) A name for the scurvy, because the gums, arms, and legs, are affected with it.

Gingi'dium. A species of *Daucus.*

Gi'ngihil. See *Zingiber.*

Gingipe'dium. (From *gingivæ*, the gums, and *pes*, the foot.) A name for the scurvy, because the gums, arms, and legs, are affected.

GINGI'VÆ. (From *gigno*, to beget; because the teeth are, as it were, born in them.) The gums. See *Gums.*

GI'NGLYMUS. (Γιγγλυμος, a hinge.) The hinge-like joint. A species of diarthrosis, or moveable connection of bones, which admits of flexion and extension, as the knee-joint, &c.

GI'NSENG. An Indian word. See *Panax quinquefolium.*

Gir. Quick-lime.

Gi'rmir. Tartar.

GITHAGO. A name used by Pliny, for the *Lolium*, or darnel-grass.

GIZZARD. The stomach of poultry. Those from white flesh, have long been considered, in France, as medicinal. They have been recommended in obstructions of the urinary passages, complaints of the bladder, and nephritic pains; but particularly as a febrifuge. Bouillon Lagrange considers its principal substance as oxygenated gelatine, with a small quantity of extractive matter.

Glabe'lla. (From *glaber*, smooth; because it is without hair.) The space betwixt the eyebrows.

GLABER. Glabrous; smooth; applied to stems, leaves, seeds, &c. of plants, and opposed to all kinds of hairiness and pubescence; as in the stem of the *Euphorbia peplus*, and the seeds of *Galium montanum.*

GLACIES. Ice.

GLADI'OLUS. (Diminutive of *gladius*, a sword; so named from the sword-like shape of its leaf.) The name of a genus of plants in the Linnæan system. Class, *Triandria*; Order, *Monogynia.*

Gladiolus luteus. See *Iris pseudacorus.*

Gla'ma. Γλαμα. The sordes of the eye.

GLAND. *Glans. Glandula.* I. In anatomy, an organic part of the body, composed of blood vessels, nerves, and absorbents, and destined for the secretion or alteration of some peculiar fluid. The glands of the human body are divided, by anatomists, into different classes, either according to their structure, or the fluid they contain. According to their fabric, they are distinguished into four classes:

1. Simple glands.
2. Compounds of simple glands.
3. Conglobate glands.
4. Conglomerate glands.

According to their fluid contents, they are more properly divided into,

1. Mucous glands.
2. Sebaceous glands.
3. Lymphatic glands.
4. Salival glands.
5. Lachrymal glands.

1. *Simple glands* are small hollow follicles, covered with a peculiar membrane, and having a proper excretory duct, through which they evacuate the liquor contained in their cavity. Such are the mucous glands of the nose, tongue, fauces, trachea, stomach, intestine and urinary bladder, the sebaceous glands about the anus, and those of the ear. These simple glands are either dispersed here and there, or are contiguous to one another, forming a heap in such a manner that they are not covered by a common membrane, but each hath its own excretory duct, which is never joined to the excretory duct of another gland. The former are termed solitary simple glands, the latter aggregate or congregate simple glands.

2. *The compound glands* consist of many simple glands, the excretory ducts of which are joined in one common excretory duct; as the sebaceous glands of the face, lips, palate, and various parts of the skin, especially about the pubes.

3. *Conglobate*, or, as they are also called, *lymphatic glands*, are those into which lymphatic vessels enter, and from which they go out again: as the mesenteric, lumbar, &c. They have no excretory duct, but are composed of a texture of lymphatic vessels connected together by cellular membrane: they are the largest in the fœtus.

4. *Conglomerate glands* are composed of a congeries of many simple glands, the excretory ducts of which open into one common trunk: as the parotid gland, thyroid gland, pancreas, and all the salival glands. Conglomerate glands differ but little from the compound glands, yet they are composed of more simple glands than the compound.

The excretory duct of a gland is the duct through which the fluid of the gland is excreted. The vessels and nerves of glands always come from the neighbouring parts, and the arteries appear to possess a high degree of irritability. The use of the glands is to separate a peculiar liquor, or to change it. The use of the conglobate glands is unknown.

II. In botany, Linnæus defines it, a little tumour discharging a fluid.

From their situation they are said to be,

1. *Foliares*, when on the surface of the leaf; as in the *Gossypium religiosum*, which has one gland on the leaf; and *Gossypium barbadense*, the leaves of which have three.

2. *Petiolares*, when in the foot-stalk; as in *Prunus cerasus*.

3. *Corollares*. The claw of the corolla of the *Berberis vulgaris* has two glands.

4. *Filamentares*, in the filaments; as in *Dictamnus albus*.

From their adhesion,

1. *Glandula sessilis*, without any peduncle; as in *Prunus cerasus*.

2. *Glandula pedicillata*, furnished with a peduncle; as in *Drosera*.

Glands are abundant on the stalk and calyx of the moss-rose, and between the serratures of the leaf of the *Salix pentandria*; on the footstalks of the *Viburnum opulus*, and various species of passion-flower. The liquor discharged is resinous and fragrant.

GLANDORP, MATTHIAS LOUIS, was born at Cologne in 1595. Soon after commencing his medical pursuits, he went to Padua, which had at that time great reputation. He improved so much in anatomy under Spigelius, that he was deemed competent to give public demonstrations: and he took his degree in 1618. He settled in Bremen, whence his family originated; and he was so successful in practice, that he was raised to the most honourable offices. He was physician to the archbishop, and to the republic, when he died in 1640. He left several works, with plates, containing many important observations on anatomy, &c. The principal are his "Speculum Chirurgorum," and a Treatise on Issues and Setons. He was very partial to the use of the actual cautery, even in the most common disorders.

GLA'NDULA. (A diminutive of *glans*, a gland.) A small gland. See *Gland*.

GLANDULA LACHRYMALIS. See *Lachrymal gland*.

GLANDULÆ MYRTIFORMES. See *Carunculæ myrtiformes*.

GLANDULÆ PACCHIONIÆ. A number of small, oval, fatty substances, not yet ascertained to be glandular, situated under the dura mater, about the sides of the longitudinal sinus. Their use is not known.

GLANDULOSOCA'RNEUS. An epithet given by Ruysch to some excrescences, which he observed in the bladder.

GLANDULOSUS. Glandular. 1. In anatomy, having the appearance, structure, or function of a gland.

2. In botany, applied to leaves which have little glandiform elevations; as the bay-leaved willow, and *Hypericum montanum*.

GLANS. A gland, or nut. See *Gland*.

GLANS PENIS. The very vascular body that forms the apex of the penis. The posterior circle is termed the *corona glandis*. See *Corpus spongiosum urethræ*.

GLANS UNGUENTARIA. See *Guilandina moringa*.

GLASS. This substance was formerly employed by surgeons, when roughly powdered, to destroy opacities of the cornea.

Glass of Antimony. See *Antimony*.

Glass-wort, snail-seeded. See *Salsola kali*.

GLA'STUM. (*Quasi callastum; from Callia*, who first used it.) The herb woad. See *Isatis tinctoria*.

Glauber's salt. A sulphate of soda. It is found native in Bohemia, and is the produce of art. See *Sodæ Sulphas*.

GLAUBERITE. A native crystallised salt, composed of dry sulphate of lime, and dry sulphate of soda, found in rock salt at Villarubra in Spain.

GLAUCEDO. (From γλαυκος, bluish, or greenish tint.) See *Glaucoma*.

GLAU'CIUM. (So named from its glaucous or sea-green colour. The name of a genus of plants in the Linnæan system. Class, *Polyandria*; Order, *Monogynia*.) The horned poppy.

GLAUCO'MA. (From γλαυκος, blue; because of the eye becoming of a blue, or sea-green colour.) *Glaucedo; Glaucosis; Apoglaucosis*. 1. An opacity of the vitreous humour. It is difficult to ascertain, and is only to be known by a very attentive examination of the eye.

2. A species of cataract. See *Cataract*.

GLAUCO'SIS. See *Glaucoma*.

GLAUCUS. (Γλαυκος, sea-green.) Stems are called glaucous which are clothed with a fine sea-green mealiness, which easily rubs off; as in *Chlora perfoliata*.

GLECO'MA. (From γληχων, the name of a plant in Dioscorides.) Class, *Didynamia*; Order, *Gymnospermia*. The name of a genus of plants in the Linnæan system. Ground-ivy.

GLECOMA HEDERACEA. The systematic name of the ground-ivy or gill. *Hedera terrestris. Glecoma—foliis reniformibus crenatis*, of Linnæus. This indigenous plant has a peculiar strong smell, and a bitterish somewhat aromatic taste. It is one of those plants which was formerly much esteemed for possessing virtues that, in the present age, cannot be detected. In obstinate coughs, it is a favourite remedy with the poor.

GLE'CHON. (Γληχων.) Pennyroyal.

GLECHONI'TES. (From γληχων, pennyroyal.) Wine impregnated with pennyroyal.

GLEET. In consequence of the repeated attacks of gonorrhœa, and the debility of the part occasioned thereby, it not unfrequently happens, that a gleet, or constant small discharge takes place, or remains behind, after all danger of infection is removed. Mr. Hunter remarks, that it differs from gonorrhœa in being *uninfectious*, and in the discharge consisting of globular particles, contained in a slimy mucus, instead of serum. It is unattended with pain, scalding in making of water, &c.

GLE'NE. Γληνη. Strictly signifies the cavity or socket of the eye; but by some anatomists is also used for that cavity of a bone which receives another within it.

GLE'NOID. (*Glenoides*; from γληνη, a cavity, and ειδος, resemblance.) The name of articulate cavities of bones.

GLEU'CINUM. (From γλευκος, must.) An ointment, in the preparation of which was must.

GLEU'XIS. (From γλευκυς, sweet.) A sweet wine.

GLIADINE. See *Gluten*.

GLI'SCERE. To increase gradually, properly as fire does; but, by physical writers, is sometimes applied to the natural heat and increase of spirits; and by others to the exacerbation of fevers which return periodically.

GLISCHRO'CHOLOS. (From γλισχρος, viscid, and χολη, the bile.) Viscid bilious excrement.

GLISCRA'SMA. (From γλισχραινω, to become glutinous.) Viscidity.

GLISOMA'RGO. White chalk.

GLISSON, FRANCIS, was born in Dorsetshire, 1597. He studied at both the English universities, but took his degree of doctor in Cambridge, where he was made Regius professor of Physic, which office he held about forty years. He settled, however, to practise in London, and became a Fellow of the College in 1635; four years after which he was chosen reader of Anatomy, and distinguished himself much by his lectures "De Morbis Partium," which he was requested to publish. During the civil wars he retired to Colchester, where he practised with great credit; and was there during the siege of that town by the parliamentary forces. He was one of the members of the society, which, about the year 1645, held weekly meetings in London to promote Natural Philosophy; and which having removed to Oxford during the troubles, was augmented after the Restoration, and became ultimately the present Royal Society. He was afterwards several years president of the College of Physicians, and died at the advanced age of 80. He left the following valuable works: 1. A Treatise on the Rickets. 2. The Anatomy of the Liver, which he described much more accurately than any one before, and particularly the capsule of the Vena Portarum, which has since been named after him. 3. A large metaphysical treatise "De Natura Substantiæ Energetica," after the manner of Aristotle. 4. A Treatise on the Stomach, Intestines, &c. a well-arranged and comprehensive work, with various new observations, which came out the year before his death.

Glisson's Capsule. See *Capsule of Glisson.*

GLOBATE. See *Gland.*

GLOBOSUS. Globose. A root is so called which is rounded, and gives off radicles in every direction; as that of the *Cyclamen europeum.* The receptacle of the *Cephalanthus* and *Nauclea,* are so called from their form.

GLOBULA'RIA. (From *globus,* a globe: so called from the shape of its flower.) The French daisy.

GLOBULA'RIA ALYPUM. The leaves of this plant are used in some parts of Spain in the cure of the venereal disease. It is said to act also as a powerful but safe cathartic.

GLO'BUS. A ball.

GLOBUS HYSTERICUS. The air rising in the œsophagus, and prevented by spasm from reaching the mouth, is so called by authors, because it mostly attends hysteria, and gives the sensation of a ball ascending in the throat.

GLOCHIS. (Γλωχις, *cuspis teli.*) A pointed hair. A sharp point; used in botany to a bristle-like pubescence, which is turned backwards at its point into many straight teeth.

GLO'MER. A clue of thread. A term mostly applied to glands.

GLOMERATE. A gland is so called which is formed of a glomer of sanguineous vessels, having no cavity, but furnished with an excretory duct; as the lachrymal and mammary glands.

GLOMERULUS. In botany, a small tuft, or *capitulum,* mostly in the axilla of the peduncle.

GLOSSA'GRA. (From *γλωσσα,* the tongue, and *αγρα,* a seizure.) A violent pain in the tongue.

GLO'SSO. (From *γλωσσα,* the tongue.) Names compounded with this word belong to muscles, nerves, or vessels, from their being attached, or going to the tongue.

GLOSSO-PHARYNGEAL NERVES. The ninth pair of nerves. They arise from the processes of the cerebellum, which run to the medulla spinalis, and terminate by numerous branches in the muscles of the tongue and pharynx.

GLOSSO-PHARYNGEUS. See *Constrictor pharyngeus superior.*

GLOSSO-STAPHYLINUS. See *Constrictor isthmi faucium.*

GLOSSOCA'TOCHOS. (From *γλωσσα,* tongue, and *κατεχω,* to hold.) An instrument in P. Ægineta for depressing the tongue. A spatula linguæ. The ancient glossocatochus was a sort of forceps, one of the blades of which served to depress the tongue, while the other was applied under the chin.

GLOSSOCE'LE. (From *γλωσσα,* the tongue, and *κηλη,* a tumour.) An extrusion of the tongue.

GLOSSOCOMA. A retraction of the tongue.

GLOSSOCOMI'ON. (From *γλωσσα,* a tongue, and *κομεω,* to guard.) By this was formerly meant a case for the tongue, for a hautboy; but the old surgeons, by metaphor, use it to signify an instrument, or case, for containing a fractured limb.

GLO'TTA. (*Γλωττα,* the tongue.) The tongue.

GLO'TTIS. (From *γλωττα,* the tongue.) The superior opening of the larynx at the bottom of the tongue.

GLUCINA. (From *γλυκυς,* which signifies sweet, because it gives that taste to the salts in forms.) The name of an earth, for the discovery of which we are indebted to Vauquelin, who found it, in 1795, in the Aigue-marine or beryl, a transparent stone, of a green colour, and in the emerald of Peru. It exists combined with silex, alumine, lime, and oxide of iron, in the one; and with the same earths, and oxide of chrome, in the other. It has lately been discovered in the gadolinite by Mr. Ekeberg.

Glucina is white, light, and soft to the touch. It is insipid, and adheres to the tongue; and is infusible by itself in the fire. Its specific gravity is 2.967. It is soluble in alkalies and their carbonates, and in all the acids except the carbonic and phosphoric, and forms with them saccharine and slightly astringent salts. It is exceedingly soluble in sulphuric acid used to excess. It is fusible with borax, and forms with it a transparent glass. It absorbs one-fourth of its weight of carbonic acid. It decomposes sulphate of alumine. It is not precipitated by the hydro-sulphurets nor by prussiate of potassa, but by all the succinates. Its affinity for the acids is intermediate between magnesia and alumine.

To obtain this earth, reduce some beryl to an impalpable powder, fuse it with three times its weight of potassa, and dissolve the mass in muriatic acid. Separate the silex by evaporation and filtration, and decompose the remaining fluid by adding carbonate of potassa; redissolve the deposit when washed in sulphuric acid, and by mingling this solution with sulphate of potassa, alum will be obtained, which crystallises.

Then mix the fluid with a solution of carbonate of ammonia, which must be used in excess; filter and boil it, and a white powder will gradually fall down, which is glucine.

GLUE. An inspissated jelly made from the parings of hides and other offals, by boiling them in water, straining through a wicker basket, suffering the impurities to subside, and then boiling it a second time. The articles should first be digested in lime water, to cleanse them from grease and dirt; then steeped in water, stirring them well from time to time; and, lastly, laid in a heap, to have the water pressed out, before they are put into the boiler. Some recommend, that the water should be kept as nearly as possible to a boiling heat, without suffering it to enter into ebullition. In this state it is poured into flat frames or moulds, then cut into square pieces when congealed, and afterwards dried in a coarse net. It is said to improve by age; and that glue is reckoned the best, which swells considerably without dissolving by three or four days' infusion in cold water, and recovers its former dimensions and properties by drying. Shreds or parings of vellum, parchment, or white leather, make a clear and almost colourless glue.

GLUMA. (*Gluma, à glubendo*, a husk of corn.) The husk. The peculiar calyx of grasses and grass-like plants, of a chaffy texture, formed of little concave leaflets which are called *valves*. To the husk belongs the *arista*, the *beard* or *awn*. See *Arista*.

The gluma is,

1. *Univalve*, in *Loilum perenne*.
2. *Bivalve*, in most grasses.
3. *Trivalved* in *Panicum maliaceum*.
4. *Many-valved*, in *Uniola paniculata*.
5. *Coloured*, otherwise than green; as in *Holcus bicolor*.

From the number of flowers the husk contains, it is called,

1. *Gluma uniflora*, one-flowered; as in *Panicum*.
2. *G. biflora*, with two; as in *Aira*.
3. *G. multiflora*, having many; as in *Poa* and *Avena*.

From the external appearance, the gluma is termed,

1. *Glabrous*, smooth; as in *Holcus laxus*.
2. *Hispid*, bristly; as in *Secale orientale*.
3. *Striate*; as in *Holcus striatus*.
4. *Villose*; as in *Holcus sorgham*, *Holcus saccharatus*, and *Bromus purgans*.
5. *Ciliate*, fringed; as in *Bromus ciliatus*.
6. *Beardless*; as in *Briza* and *Poa*.
7. *Awned*; as in *Hordeum*.

GLUMOSUS. A flower is so called, which is aggregate, and has a glumous or husky calyx.

GLUTEAL. Belonging to the buttocks.

Gluteal artery. A branch of the internal iliac artery.

GLU'TEN. (*Quasi geluten*; from *gelo*, to congeal.) See *Glue*.

Gluten, animal. This substance constitutes the basis of the fibres of all the solid parts. It resembles in its properties the gluten of vegetables.

Gluten, vegetable. If wheat-flower be made into a paste, and washed in a large quantity of water, it is separated into three distinct substances: a mucilaginous saccharine matter, which is readily dissolved in the liquor, and may be separated from it by evaporation; starch, which is suspended in the fluid, and subsides to the bottom by repose; and gluten, which remains in the hand, and is tenacious, very ductile, somewhat elastic, and of a brown-grey colour. The first of these substances does not essentially differ from other saccharine mucilages. The second, namely, the starch, forms a gluey fluid by boiling in water, though it is scarcely, if at all, acted upon by that fluid when cold. Its habitudes and products with the fire, or with nitric acid, are nearly the same as those of gum and of sugar. It appears to be as much more remote from the saline state than gum, as gum is more remote from that state than sugar.

The vegetable gluten, though it existed before the washing in the pulverulent form, and has acquired its tenacity and adhesive qualities from the water it has imbibed, is nevertheless totally insoluble in this fluid. It has scarcely any taste. When dry, it is semitransparent, and resembles glue in its colour and appearance. If it be drawn out thin, when first obtained, it may be dried by exposure to the air; but if it be exposed to warmth and moisture while wet, it putrifies like an animal substance. The dried gluten applied to the flame of a candle, crackles, swells, and burns, exactly like a feather, or piece of horn. It affords the same products by destructive distillation as animal matters do; is not soluble in alkohol, oils, or æther; and is acted upon by acids and alkalies, when heated. According to Rouelle, it is the same with the caseous substance of milk.

Gluten of Wheat.—Taddey, an Italian chemist, has lately ascertained that the gluten of wheat may be decomposed into two principles, which he has distinguished by the names, *gliadine* (from γλια, gluten,) and *zimome* (from ζυμη, ferment.) They are obtained in a separate state by kneading the fresh gluten in successive portions of alkohol, as long as that liquid continues to become milky, when diluted with water. The alkohol solutions being set aside, gradually deposit a whitish matter, consisting of small filaments of gluten, and become perfectly transparent. Being now left to slow evaporation, the gliadine remains behind, of the consistence of honey, and mixed with a little yellow resinous matter, from which it may be freed by digestion in sulphuric æther, in which gliadine is not sensibly soluble. The portion of the gluten not dissolved by the alkohol is the *zimome*.

Properties of Gliadine.—When dry, it has a straw-yellow colour, slightly transparent, and in thin plates, brittle, having a slight smell, similar to that of honey-comb, and, when slightly heated, giving out an odour similar to that of boiled apples. In the mouth it becomes adhesive, and has a sweetish and balsamic taste. It is pretty soluble in boiling alkohol, which loses its transparency in proportion as it cools, and then retains only a small quantity in solution. It forms a kind of varnish in those bodies to which it is applied. It softens, but does not dissolve in cold distilled water. At a boiling heat it is converted into froth, and the liquid remains slightly milky. It is specifically heavier than water.

The alkoholic solution of gliadine becomes milky when mixed with water, and is precipitated in white flocks by the alkaline carbonates. It is scarcely affected by the mineral and vegetable acids. Dry gliadine dissolves in caustic alkalies and in acids. It swells upon red-hot coals, and then contracts in the manner of animal substances. It burns with a pretty lively flame, and leaves behind it a light spongy charcoal, difficult to incinerate. Gliadine, in some respects, approaches the properties of resins; but differs from them in being insoluble in sulphuric æther. It is very sensibly affected by the infusion of nut galls. It is capable of itself of undergoing a slow fermentation, and produces fermentation in saccharine substances.

From the flour of barley, rye, or oats, no gluten can be extracted as from that of wheat, probably because they contain too small a quantity.

The residue of wheat which is not dissolved by alkohol, is called *zimome*. If this be boiled repeatedly in alkohol, it is obtained pure.

Zimome thus purified has the form of small globules, or constitutes a shapeless mass, which is hard, tough, destitute of cohesion, and of an ash-white colour. When washed in water, it recovers part of its viscosity, and becomes quickly brown, when left in contact with the air. It is specifically heavier than water. Its mode of fermenting is no longer that of gluten; for when it purifies it exhales a fœtid urinous odour. It dissolves completely in vinegar, and in the mineral acids at a boiling temperature. With caustic potassa, it combines and forms a kind of soap, When put into lime water, or into the solutions of the alkaline carbonates, it becomes harder, and assumes a new appearance without dissolving. When thrown upon red-hot coals, it exhales an odour similar to that of burning hair or hoofs, and burns with flame.

Zimome is to be found in several parts of vegetables. It produces various kinds of fermentation, according to the nature of the substance with which it comes in contact.

GLUTE'US. (From γλουτος, the buttocks.) The name of some muscles of the buttocks.

GLUTEUS MAXIMUS. *Gluteus magnus* of Albinus. *Glutæus major* of Cowper; and *Ilio sacro femoral* of Dumas. A broad radiated muscle, on which we sit, is divided into a number of strong fasciculi, is covered by a pretty thick aponeurosis derived from the *fascia lata*, and is situated immediately under the integuments. It arises fleshy from the outer lip of somewhat more than the posterior half of the spine of the ilium, from the ligaments that cover the two posterior spinous processes; from the posterior sacro-ischiatic ligament; and from the outer sides of the os sacrum and os coccygis. From these origins the fibres of the muscle run towards the great trochanter of the os femoris, where they form a broad and thick tendon, between which and the trochanter there is a considerable *bursa mucosa*. This tendon is inserted into the upper part of the *linea aspera*, for the space of two or three inches downwards; and sends off fibres to the fascia lata, and to the upper extremity of the vastus externus. This muscle serves to extend the thigh, by pulling it directly backwards; at the same time it draws it a little outwards, and thus assists in its rotatory motion. Its origin from the coccyx seems to prevent that bone from being forced too far backwards.

GLUTEUS MEDIUS. *Ilio trochanterien* of Dumas. The posterior half of this muscle is covered by the gluteus maximus, which it greatly resembles in shape; but the anterior and upper part of it is covered only by the integuments, and by a tendinous membrane which belongs to the fascia lata. It arises fleshy from the outer lip of the anterior part of the spine of the ilium, from part of the posterior surface of that bone, and likewise from the fascia that covers it. From these origins its fibres run towards the great trochanter, into the outer and posterior part of which it is inserted by a broad tendon. Between this tendon and the trochanter there is a small thin *bursa mucosa*. The uses of this muscle are nearly the same as those of the gluteus maximus; but it is not confined, like that muscle, to rolling the os femoris outwards, its anterior portion being capable of turning that bone a little inwards. As it has no origin from the coccyx, it can have no effect on that bone.

GLUTEUS MINIMUS. *Glutæus minor* of Albinus and Cowper; and *Ilio ischii trochanterien* of Dumas. A radiated muscle is situated under the gluteus medius. In adults, and especially in old subjects, its outer surface is usually tendinous. It arises fleshy between the two semicircular ridges we observe on the outer surface of the ilium, and likewise from the edge of its great niche. Its fibres run, in different directions, towards a thick flat tendon, which adheres to a capsular ligament of the joint, and is inserted into the fore and upper part of the great trochanter. A small *bursa mucosa* may be observed between the tendon of this muscle and the trochanter. This muscle assists the two former in drawing the thigh backwards and outwards, and in rolling it. It may likewise serve to prevent the capsular ligament from being pinched in the motions of the joint.

GLU'TIA. (From γλουτος, the buttocks.) The buttocks. See *Nates*.

GLUTTU'PATENS. (From *gluttus*, the throat, and *pateo*, to extend.) The stomach, which is an extension of the throat.

GLU'TUS. (Γλουτος; from γλοιος, filthy.) The buttock. See *Nates*.

GLYCA'SMA. (From γλυκυς, sweet.) A sweet medicated wine.

GLYCYPI'CROS. (From γλυκυς, sweet, and πικρος, bitter: so called from its bitterish sweet taste.) See *Solanum Dulcamara*.

GLYCYRRHIZA. (From γλυκυς, sweet, and ριζα, a root.) 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria*.

2. The pharmacopœial name of liquorice. See *Glycyrrhiza glabra*.

GLYCYRRHIZA ECHINATA. This species of liquorice is substituted in some places for the root of the *glabra*.

GLYCYRRHIZA GLABRA. The systematic name of the officinal liquorice. *Glycyrrhiza; leguminibus glabris, stipulis nullis, foliolo impari petiolato.* A native of the south of Europe, but cultivated in Britain. The root contains a great quantity of saccharine matter, joined with some proportion of mucilage, and hence it has a viscid sweet taste. It is in common use as a pectoral or emollient, in catarrhall defluxions on the breast, coughs, hoarsenesses, &c. Infusions, or the extract made from it, which is called *Spanish liquorice*, afford likewise very commodious vehicles for the exhibition of other medicines; the liquorice taste concealing that of unpalatable drugs more effectually than syrups or any of the sweets of the saccharine kind.

GLYCYSA'NCON. (From γλυκυς, sweet, and αγκων, the elbow: so called from its sweetish taste, and its inflections, or elbows at the joints.) A species of southern wood.

GNAPHA'LIUM. (From γναφαλον, cotton: so named from its soft downy surface.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia superflua*.

2. The pharmacopœial name of the herb cotton weed. See *Gnaphalium dioicum*.

GNAPHALIUM ARENARIUM. The flowers of this plant, as well as those of the gnaphalium stœchas, are called in the pharmacopœias, *flores elichrysi*. See *Gnaphalium stœchas*.

GNAPHALIUM DIOICUM. The systematic name of the *pes cati*. *Gnaphalium albinum.* Cotton weed. The flores gnaphalii of the pharmacopœias, called also *flores hispidulæ, seu pedes cati*, are the produce of this plant. They are now quite obsolete, but were formerly used as astringents, and recommended in the cure of hooping-cough, phthisis pulmonalis, and hæmoptysis.

GNAPHALIUM STŒCHAS. The systematic name of Goldilocks. *Elichrysum; Stæchas citrina.* The flowers of this small downy plant are warm, pungent, and bitter, and said to possess aperient and corroborant virtues.

GNA'THUS. (From γναπτω, to bend; so called from their curvature.) 1. The jaw, or jaw-bones.

2. The cheek.

GNEISS. A compound rock, consisting of felspar, quartz, and mica, disposed in slates, from the preponderance of the mica scales.

GNI'DIUS. A term applied by Hippocrates, and others since, to some medicinal precepts wrote in the island of Gnidos.

Goat's-rue. See *Galega*.

Goat's-thorn. See *Astragalus verus.*

GOAT-WEED. See *Ægopodium.*

GOUT-WEED. See *Ægopodium podagraria.*

GODDARD, Jonathan, was born at Greenwich, in 1617. After studying at Oxford, and travelling for improvement, he graduated at Cambridge, and settled to practice in London. He was elected a Fellow of the College of Physicians in 1646, and the following year, appointed lecturer on Anatomy. He formed a Society for Experimental Enquiry, which met at his house; and he was very assiduous in promoting its objects. Having gained considerable reputation, and sided with the popular party, he was appointed by Cromwell chief physician to the army, and attended him in some of his expeditions. Cromwell then made him warden of Merton College, Oxford, afterwards sole representative of that University in the short Parliament in 1653, and in the same year one of the Council of State. On the Restoration, being driven from Oxford, he removed to Gresham College, where he had been chosen professor of Physic. Here he continued to frequent those meetings, which gave birth to the Royal Society, and he was nominated one of the first council of that institution. He was an able and conscientious practitioner; and was induced, partly from the love of experimental chemistry, but principally from doubting the competency of apothecaries, to prepare his own medicines: in which, however, finding numerous obstacles, he published "A Discourse, setting forth the unhappy Condition of the Practice of Physic in London;" but this was of no avail. Two papers of his appeared in the Philosophical Transactions, and many others in Birch's History of the Royal Society. He died in 1674 of an apoplectic stroke.

GOELICKE, Andrew Offon, a German physician, acquired considerable reputation in the beginning of the eighteenth century, as a medical professor, and especially as an advocate of the doctrines of Stahl. He left several works, which relate principally to the History of Anatomy, &c. particularly the "Historia Medicinæ Universalis," which was published in six different portions between the years 1717 and 1720.

Goitre. See *Bronchocele.*

GOLD. *Aurum.* A metal found in nature only in a metallic state; most commonly in grains, ramifications, leaves, or crystals, rhomboidal, octahedral, or pyramidal. Its matrix is generally quartz, sandstone, siliceous schistus, &c. It is found also in the sands of many rivers, particularly in Africa, Hungary, and France, in minute irregular grains, called *gold dust.* Native gold, found in compact masses, is never completely pure; it is alloyed with silver, or copper, and sometimes with iron and tellurium. The largest piece of native gold that has been hitherto discovered in Europe, was found in the county of Wicklow, in Ireland. Its weight was said to be twenty-two ounces, and the quantity of alloy it contained was very small. Several other pieces, exceeding one ounce, have also been discovered at the same place, in sand, covered with turf, and adjacent to a rivulet.

Gold is also met with in a particular sort of argentiferous copper pyrites, called in Hungary *Gelf.* This ore is found either massive, or crystallised in rhomboids, or other irregular quadrangular or polygonal masses. It exists likewise in the sulphurated ores of Nagaya in Transylvania. These all contain the metal called tellurium. Berthollet, and other French chemists, have obtained gold out of the ashes of vegetables.

GOLD-CUP. See *Ranunculus.*

GOLDEN-ROD. See *Solidago virga aurea.*

Golden maidenhair. See *Polytrichum commune.*

GOLDILOCKS. See *Gnaphalium stœchas.*

GOMPHI′ASIS. (From γομφος, a nail.) *Gomphiasmus.* A disease of the teeth, when they are loosened from the sockets, like nails drawn out of the wood.

Gomphia′smus. See *Gomphiasis.*

Go′mphioi. (From γομφος, a nail; so called because they are as nails driven into their sockets.) The dentes molares, or grinding teeth.

Gompho′ma. See *Gomphosis.*

GOMPHO′SIS. (From γομφοω, to drive in a nail.) *Gomphoma.* A species of immoveable connection of bones, in which one bone is fixed in another, like a nail in a board, as the teeth in the alveoli of the jaws.

GONA′LGIA. See *Gonyalgia.*

GONA′GRA. (From γονυ, the knee, and αγρα, a seizure.) The gout in the knee.

GO′NE. (γονη.) 1. The seed.

2. In Hippocrates it is the uterus.

GONG. Tam-tam. A species of cymbal which produces a very loud sound when struck. It is an alloy of about eighty parts of copper with twenty of tin.

GONGRO′NA. (From γογγρος, a hard knot.) 1. The cramp.

2. A knot in the trunk of a tree.

3. A hard round tumour of the nervous parts; but particularly a bronchocele, or other hard tumour of the neck.

Gongy′lion. (From γογγυλος, round.) A pill.

GONIOMETER. An instrument for measuring the angles of crystals.

GONOI′DES. (From γονη, seed, and ειδος, form.) Resembling seed. Hippocrates often uses it as an epithet for the excrements of the belly, and for the contents of the urine, when there is something in them which resembles the seminal matter.

GONORRHŒ′A. (From γονη, the semen, and ρεω, to flow; from a supposition of the ancients, that it was a seminal flux.) A genus of disease in the class *Locales*, and order *Apocenoses* of Dr. Cullen's arrangement, who defines it a preternatural flux of fluid from the urethra in males, with or without libidinous desires. Females, however, are subject to the same complaint in some forms. He makes four species, viz.

1. *Gonorrhœa pura* or *benigna;* a puriform discharge from the urethra, without dysuria, or lascivious inclination, and not following an impure connection.

2. *Gonorrhœa impura, maligna, syphilitica, virulenta;* a discharge resembling pus, from the urethra, with heat of urine, &c. after impure coition, to which often succeeds a discharge of mucus from the urethra, with little or no dysury, called a gleet. This disease is also called *Fluor albus malignus. Blennorrhagia* by Swediaur. In English, a *clap*, from the old French word *clapises*, which were public shops, kept and inhabited by single prostitutes, and generally confined to a particular quarter of the town, as is even now the case in several of the great towns in Italy. In Germany, the disorder is named *tripper*, from dripping; and in French, *chaudpisse*, from the heat and scalding in making water.

No certain rule can be laid down with regard to the time that a clap will take before it makes its appearance, after infection has been conveyed. With some persons it will show itself in the course of three or four days, whilst, with others, there will not be the least appearance of it before the expiration of some weeks. It most usually is perceptible, however, in the space of from six to fourteen days, and in a male, begins with an uneasiness about the parts of generation, such as an itching in the glans penis, and a soreness and tingling sensation along the whole course of the urethra; soon after which, the person perceives an appearance of whitish matter at its orifice, and also some degree of pungency upon making water.

In the course of a few days, the discharge of matter will increase considerably; will assume, most probably, a greenish or yellowish hue, and will become thinner, and lose its adhesiveness; the parts will also be occupied with some degree of redness and inflammation, in consequence of which the glans will put on the appearance of a ripe cherry, the stream of urine will be smaller than usual, owing to the canal being made narrower by the inflamed state of its internal membrane, and a considerable degree of pain, and scalding heat, will be experienced on every attempt to make water.

Where the inflammation prevails in a very high degree, it prevents the extension of the urethra, on the taking place of any erection, so that the penis is, at that time, curved downwards, with great pain, which is much increased, if attempted to be raised towards the belly, and the stimulus occasions it often to be erected, particularly when the patient is warm in bed, and so deprives him of sleep, producing, in some cases, an involuntary emission of semen.

In consequence of the inflammation, it sometimes happens that, at the time of making water, owing to the rupture of some small blood vessel, a slight hæmorrhage ensues, and a small quantity of blood is voided. In consequence of inflammation, the prepuce likewise becomes often so swelled at the end that it cannot be drawn back, which symptom is called a phimosis; or, that being drawn behind the glans, it cannot be returned, which is known by the name of paraphimosis. Now and then, from the same cause, little hard swellings arise on the lower surface of the penis, along the course of the urethra, and these perhaps suppurate and form into fistulous sores.

The adjacent parts sympathising with those already affected, the bladder becomes irritable, and incapable of retaining the urine for any length of time, which gives the patient a frequent inclination to make water, and he feels an uneasiness about the scrotum, perinæum, and fundament. Moreover, the glands of the groins grow indurated and enlarged, or perhaps the testicles become swelled and inflamed, in consequence of which he experiences excruciating pains, extending from the seat of the complaint up into the small of the back; he gets hot and restless, and a small symptomatic fever arises.

Where the parts are not occupied by much inflammation, few or none of the last-mentioned symptoms will arise, and only a discharge with a slight heat or scalding in making water will prevail.

If a gonorrhœa be neither irritated by any irregularity of the patient, nor prolonged by the want of timely and proper assistance, then, in the course of about a fortnight, or three weeks, the discharge, from having been thin and discoloured at first, will become thick, white, and of a ropy consistence; and from having gradually begun to diminish in quantity, will at last cease entirely, together with every inflammatory symptom whatever; whereas, on the contrary, if the patient has led a life of intemperance and sensuality, has partaken freely of the bottle and high seasoned meats, and has, at the same time, neglected to pursue the necessary means, it may then continue for many weeks or months; and, on going off, may leave a weakness or gleet behind it, besides being accompanied with the risk of giving rise, at some distant period, to a constitutional affection, especially if there has been a neglect of proper cleanliness; for where venereal matter has been suffered to lodge between the prepuce and glans penis for any time, so as to have occasioned either excoriation or ulceration, there will always be danger of its having been absorbed.

Another risk, arising from the long continuance of a gonorrhœa, especially if it has been attended with inflammatory symptoms, or has been of frequent recurrence, is the taking place of one or more strictures in the urethra. These are sure to occasion a considerable degree of difficulty, as well as pain, in making water, and, instead of its being discharged in a free and uninterrupted stream, it splits into two, or perhaps is voided drop by drop. Such affections become, from neglect, of a most serious and dangerous nature, as they not unfrequently block up the urethra, so as to induce a total suppression of urine.

Where the gonorrhœa has been of long standing, warty excrescences are likewise apt to arise about the parts of generation, owing to the matter falling and lodging thereon; and they not unfrequently prove both numerous and troublesome.

Having noticed every symptom which usually attends on gonorrhœa, in the male sex, it will only be necessary to observe, that the same heat and soreness in making water, and the same discharge of discoloured mucus, together with a slight pain in walking, and an uneasiness in sitting, take place in females as in the former; but as the parts in women, which are most apt to be affected by the venereal poison, are less complex in their nature, and fewer in number, than in men, so of course the former are not liable to many of the symptoms which the latter are; and, from the urinary canal being much shorter, and of a more simple form, in them than in men, they are seldom, if ever, incommoded by the taking place of strictures.

With women, it indeed often happens, that all the symptoms of a gonorrhœa are so very slight, they experience no other inconvenience than the discharge, except perhaps immediately after menstruation, at which period, it is no uncommon occurrence for them to perceive some degree of aggravation in the symptoms.

Women of a relaxed habit, and such as have had frequent miscarriages, are apt to be afflicted with a disease known by the name of fluor albus, which it is often difficult to distinguish from gonorrhœa virulenta, as the matter discharged in both is, in many cases, of the same colour and consistence. The surest way of forming a just conclusion, in instances of this nature, will be to draw it from an accurate investigation, both of the symptoms which are present and those which have preceded the discharge; as likewise from the concurring circumstances, such as the character and mode of life of the person, and the probability there may be of her having had venereal infection conveyed to her by any connexion in which she may be engaged.

Not long ago, it was generally supposed that gonorrhœa depended always upon ulcers in the urethra, producing a discharge of purulent matter; and such ulcers do, indeed, occur in consequence of a high degree of inflammation and suppuration; but many dissections of persons, who have died whilst labouring under a gonorrhœa, have clearly shown that the disease may, and often does, exist without any ulceration in the urethra, so that the discharge which appears is usually of a vitiated mucus, thrown out from the mucous follicles of the urethra. On opening this canal, in recent cases, it usually appears red and inflamed; its mucous glands are somewhat enlarged, and its cavity is filled with matter to within a small distance from its extremity. Where the disease has been of long continuance, its surface all along, even to the bladder, is generally found pale and relaxed, without any erosion.

3. *Gonorrhœa laxorum, libidinosa;* a pellucid discharge from the urethra, without erection of the penis, but with venereal thoughts while awake.

4. *Gonorrhœa dormientium. Oneirogonos.* When, during sleep, but dreaming of venereal engagements, there is an erection of the penis, and a seminal discharge.

GONORRHŒA BALANI. A species of gonorrhœa affecting the glans penis only.

GONYA'LGIA. (From *γονυ*, the knee, and *αλγος*, pain.) *Gonialgia; Gonalgia.* Gout in the knee.

GOOSE. *Anser.* The *Anser domesticus,* or tame goose.

GOOSE-FOOT. See *Chenopodium.*

GOOSE-GRASS. See *Galium aparine.*

GO'RDIUS. 1. The name of a genus of the Order *Vermes*, of animals.

2. The gordius, or hair-tail worm, of old writers, which is the *seta equina* found in stagnant marshes and ditches in Lapland, and other places.

GORDIUS MEDINENSIS. The systematic name of a curious animal. See *Medinensis vena.*

GORGONIA. The name of a genus of corals.

GORGONIA NOBILIS. The red coral.

GOSSY'PIUM. (From *gotne*, whence *gottipium*, Egyptian.) 1. The name of a genus of plants in the Linnæan system. Class, *Monadelphia;* Order, *Polyandria.*

2. The pharmacopœial name of the cotton-tree. See *Gossypium herbaceum.*

GOSSYPIUM HERBACEUM. The systematic name of the cotton-plant. *Gossypium; Bombax. Gossypium—foliis quinquelobis subtus eglandulosis, caule herbaceo,* of Linnæus. The seeds are directed for medicinal use in some foreign pharmacopœias; and are administered in coughs, on account of the mucilage they contain. The cotton, the produce of this tree, is well known for domestic purposes.

Goulard's Extract. A saturated solution of acetate of lead. See *Plumbi acetatis liquor.*

GOULSTON, THEODORE, was born in Northamptonshire. After studying medicine at Oxford, he practised for a time with considerable reputation at Wymondham, of which his father was rector. Having taken his doctor's degree in 1610, he removed to London, and became a fellow of the College of Physicians. He was much esteemed for classical and theological learning, as well as in his profession. He died in 1632; and bequeathed 200*l.* to purchase a rent-charge for maintaining an annual Pathological Lecture, to be read at the college by one of the four junior doctors. He translated and wrote learned notes on some of the works of Aristotle and Galen; of which the latter were not published till after his death.

GOURD. See *Cucurbita.*

Gourd, bitter. See *Cucumis colocynthis.*

GOUT. See *Arthritis*, and *Podagra.*

Gout stone. See *Chalk stone.*

GRAAF, REINIER DE, was born at Schoonhove in Holland, 1641. He studied physic at Leyden, where he made great progress, and at the age of 22, published his treatise "De Succo Pancreatico," which gained him considerable reputation. Two years after he went to France, and graduated at Angers; he then returned to his native country, and settled at Delft, where he was very successful in practice; but he died at the early age of 32. He published three dissertations relative to the organs of generation in both sexes; upon which he had a controversy with Swammerdam.

GRA'CILIS. (So named from its smallness.) *Rectus interior femoris, sive gracilis interior* of Winslow. *Sous pubio creti tibial* of Dumas. A long, straight, and slender muscle, situated immediately under the integuments at the inner part of the thigh. It arises by a broad and thin tendon, from the anterior part of the ischium and pubis, and soon becoming fleshy, descends nearly in a straight direction along the inside of the thigh. A little above the knee, it terminates in a slender and roundish tendon, which afterwards becomes flatter, and is inserted into the middle of the tibia, behind and under the sartorius. Under the tendons of this and the rectus, there is a considerable *bursa mucosa*, which on one side adheres to them and to the tendon of the semitendinosus, and on the other to the capsular ligament of the knee. This muscle assists in bending the thigh and leg inwards.

GRÆCUS. The trivial name of some herbs found in or brought from Greece.

GRAFTING. Budding and inoculating is the process of uniting the branches or buds of two or more separate trees. The bud or branch of one tree, accompanied by a portion of its bark, is inserted into the bark of another, and the tree which is thus engrafted upon is called the stock. By this mode different kinds of fruits, pears, apples, plums, &c. each of which is only a variety accidentally raised from seed, but no further perpetuated in the same manner, are multiplied; buds of the kind wanted to be propagated being engrafted on so many stalks of a wild nature.

GRA'MEN. (*Gramen, inis.* n.) Grass. Any kind of grass-like herb.

GRAMEN ARUNDINACEUM. See *Calamagrostis.*

GRAMEN CANINUM. See *Triticum repens.*

GRAMEN CRUCIS CYPERIOIDIS. *Gramen ægyptiacum.* Egyptian cock's-foot grass, or grass of the cross. The roots and plants possess the same virtues as the dog's grass, and are serviceable in the earlier stages of dropsy. They are supposed to correct the bad smell of the breath, and to relieve nephritic disorders, colics, &c. although now neglected.

GRAMIA. The sordes of the eyes.

GRAMMATITE. See *Tremolite.*

GRA'MME. (From *γραμμη*, a line: so called from its linear appearance.) The iris of the eye.

GRANADI'LLA. (Diminutive of *granado*, a pomegranate, Spanish: so called because at the top of the flower there are points, like the grains of a pomegranate.) The passion-flower, the fruit of which is said to possess refrigerating qualities.

GRANATITE. See *Grenatite.*

GRANATRI'STUM. A boil or carbuncle.

GRANATUM. (From *granum*, a grain, because it is full of seed.) The pomegranate. See *Punica granatum.*

GRANDE'BALÆ. (*Quod in grandioribus*

ætate nascantur, because they appear in those who are advanced in years.) The hairs under the arm-pits.

GRANDINO′SUM OS. The *os cuboides*.

GRA′NDO. (*Grando, inis.* f. *Quod similitudinem granorum habeat*, because it is in shape and size like a grain of seed.)

1. Hail.

2. A moveable tumour on the margin of the eyelid is so called, from its likeness to a hail-stone.

GRANITE. A compound rock consisting of quartz, felspar, and mica, each crystallized, and cohering by mutual affinity without any basis or cement.

GRANULA′TION. (*Granulatio*; from *granum*, a grain.) 1. In surgery: The little grainlike fleshy bodies which form on the surfaces of ulcers and suppurating wounds, and serve both for filling up the cavities, and bringing nearer together and uniting their sides, are called granulations.

Nature is supposed to be active in bringing parts as nearly as possible to their original state, whose disposition, action, and structure, have been altered by accident, or disease; and after having in her operations for this purpose, formed pus, she immediately sets about forming a new matter upon surfaces, in which there has been a breach of continuity. This process is called *granulating* or *incarnation*; and the substance formed is called *granulations*. The colour of healthy granulations is a deep florid red. When livid, they are unhealthy, and have only a languid circulation. Healthy granulations, on an exposed or flat surface, rise nearly even with the surface of the surrounding skin, and often a little higher; but when they exceed this, and take on a growing disposition, they are unhealthy, become soft, spongy, and without any disposition to form skin. Healthy granulations are always prone to unite to each other, so as to be the means of uniting parts.

2. In chemistry: The method of dividing metallic substances into grains or small particles, in order to facilitate their combination with other substances, and sometimes for the purpose of readily subdividing them by weight.

GRANULATUS. Granulated. Applied to ulcers and to parts of plants. A root is so called which is jointed; as that of the *Oxalis acetocella*.

GRA′NUM. (*Granum, i.* n.) A grain or kernel.

GRANUM CNIDIUM. See *Daphne mezereum*.

GRANUM INFECTORIUM. Kermes berries.

GRANUM KERMES. Kermes berries.

GRANUM MOSCHI. See *Hibiscus abelmoschus*.

GRANUM PARADISI. See *Amomum*.

GRANUM REGIUM. The castor-oil-seed.

GRANUM TIGLII. See *Croton tiglium*.

GRANUM TINCTORIÆ. Kermes berries.

GRAPHIC ORE. An ore of tellurium.

GRAPHIOI′DES. (From *γραφις*, a pencil, and *ειδος*, a form.) 1. The styliform process of the os temporis.

2. A process of the ulna.

3. The digastricus was formerly so called from its supposed origin from the above-mentioned process of the temple bone.

GRAPHITE. Rhomboidal graphite of Jameson, or plumbago, or black-lead, of which he gives two sub-species, the scaly and compact.

GRA′SSA. Borax.

GRATI′OLA. (Diminutive of *gratia*, so named from its supposed admirable qualities.) Hyssop.

1. The name of a genus of plants in the Linnæan system. Class, *Diandria*; Order, *Monogynia*.

2. the pharmacopœial name of the hedge-hyssop. See *Gratiola officinalis*.

GRATIOLA OFFICINALIS. The systematic name of the hedge-hyssop. *Digitalis minima*; *Gratia dei*; *Gratiola centauriodes*. This exotic plant, the *Gratiola*;—*foliis lanceolatis, serratis, floribus pedunculatis*, of Linnæus, is a native of the south of Europe; but is raised in our gardens. The leaves have a nauseous bitter taste, but no remarkable smell; they purge and vomit briskly in the dose of half a drachm of the dry herb, or of a drachm infused in wine or water. This plant, in small doses, has been commonly employed as a cathartic and diuretic in hydropical diseases; and instances of its good effects in ascites and anasarca are recorded by many respectable practitioners. Gesner and Bergius found a scruple of the powder a sufficient dose, as in this quantity it frequently excited nausea or vomiting; others have given it to half a drachm, two scruples, a drachm, and even more.

An extract of the root of this plant is said to be more efficacious than the plant itself, and exhibited in the dose of half a drachm, or a drachm, in dysenteries, produces the best effect. We are also told by Kostrzewski that in the hospitals at Vienna, three maniacal patients were perfectly recovered by its use; and in the most confirmed cases of lues venerea, it effected a complete cure; it usually acted by increasing the urinary cutaneous, or salivary discharges.

GRAVE′DO. (From *gravis*, heavy.) A catarrh, or cold, with a sense of heaviness in the head.

GRAVEL. See *Calculus*.

GRAVITY. A term used by physical writers to denote the cause by which all bodies move toward each other, unless prevented by some other force or obstacle.

GRAVITY, SPECIFIC. The density of the matter of which any body is composed, compared to the density of another body, assumed as the standard. This standard is pure distilled water, at the temperature of 60° F. To determine the specific gravity of a solid, we weigh it, first in air, and then in water. In the latter case, it loses of its weight a quantity precisely equal to the weight of its own bulk of water; and hence, by comparing this weight, with its total weight, we find its specific gravity. The rule therefore is, Divide the total weight by the *loss* of weight in water, the quotient is the specific gravity. If it be a liquid or a gas, we weigh it in a glass or other vessel of known capacity; and dividing that weight by the weight of the same bulk of water, the quotient is, as before, the specific gravity.

GREEN-EARTH. Mountain green. A mineral of a celandine green colour, found in Saxony, Verona, and Hungary.

GREEN SICKNESS. See *Chlorosis*.

Green vitriol. Sulphate of iron.

GREENSTONE. A rock of the *trap* formation, consisting of a hornblend, and felspar, both in the state of grains or small crystals.

GREGORY, JOHN, was born in 1725, his father being professor of medicine at King's College, Aberdeen; after studying under whom, he went to Edinburgh, Leyden, and Paris. At the age of 20, he was elected professor of philosophy at Aberdeen, and was made doctor of medicine. In the year 1756 he was chosen professor of medicine on the death of his brother James, who had succeeded his father in that chair. But about nine years after he went to Edinburgh; and was soon appointed professor of the practice of medicine there, Dr. Rutherford having resigned in his favour. The year following, on the death of Dr. White, he was nominated first physician to the king for Scotland. He also enjoyed very extensive practice, prior to his death in 1773. He published, in 1765, "A Comparative View of the State and Faculties of Man with those of the Animal World," which contains many just and original remarks, and was very favourably received. Five years after his "Observations on the Duties and Offices of a Physician, &c." given in his introductory lectures, were made public surreptitiously; which induced him to print them in a more correct form. The work has been greatly admired. His last publication, "Elements of the Practice of Physic," was intended as a syllabus to his lectures; but he did not live to complete it.

GRENATITE. Prismatoidal garnet.

Gressu′ra. (From *gradior*, to proceed.) The perinæum which goes from the pudendum to the anus.

GREW, Nehemiah, was born at Coventry; where, after graduating at some foreign university, he settled in practice. He there formed the idea of studying the anatomy of plants. His first essay on this subject was communicated to the Royal Society in 1670, and met with great approbation: whence he was induced to settle in London, and two years after became a fellow of that society; of which he was also at one period secretary. In 1680 he was made an honorary fellow of the College of Physicians. He is said to have attained considerable practice, and died in 1711. His "Anatomy of Vegetables, Roots, and Trunks," is a large collection of original and useful facts; though his theories have been invalidated by subsequent discoveries. He had no correct ideas of the propulsion of direction of the sap; but he was one of the first who adopted the doctrine of the sexes of plants; nor did even the principles of methodical arrangement entirely escape his notice. In 1681, he published a descriptive catalogue of the Museum of the Royal Society; to which were added some lectures on the comparative anatomy of the stomach and intestines. Another publication was entitled "Cosmographia Sacra, or a Discourse of the Universe; as it is the Creature and Kingdom of God." His works were soon translated into French and Latin; but the latter very incorrectly.

GREYWACKE. A mountain formation, consisting of two similar rocks, which, alternate with, and pass into each other, called greywacke, and greywacke-slate.

GRIAS. (A name mentioned by Apuleius.) The name of a genus of plants. Class, *Polyandria*; Order, *Monogynia*.

Grias cauliflora. The systematic name of the tree, the fruit of which is the anchovy pear. The inhabitants of Jamaica esteem it as a pleasant and cooling fruit.

Grie′lum. A name formerly applied to parsley and smallage.

Gripho′menos. (From γριφος, a net; because it surrounds the body as with a net.) Applied to pains which surround the body at the loins.

GROMWELL. See *Lithospermum.*

GROSSULARE. A mineral of an asparagus-green colour, of the garnet genus.

GROSSULA′RIA. (Diminutive of *grossus*, an unripe fig; so named because its fruit resembles an unripe fig.) The gooseberry, or gooseberry-bush. See *Ribes*.

Grotto del cane. (The Italian for the dog's grotto.) A grotto near Naples, in which dogs are suffocated. The carbonic acid gas rises about eighteen inches. A man therefore, is not affected, but a dog forcibly held in, or that cannot rise above it, is soon killed unless taken out. He is recovered by plunging him in an adjoining lake.

Ground ivy. See *Glecoma hederacea.*

Ground liverwort. See *Lichen caninus.*

Ground-nut. See *Bunium bulbocastanum.*

Ground-pine. See *Teucrium chamæpitys.*

GROUNDSEL. See *Senecio vulgaris.*

GRUINALES. (From *grus*, a crane.) The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of geranium, or crane's-bill genus principally.

GRU′TUM. A hard white tubercle of the skin, resembling in size and appearance a millet-seed.

GRYLLUS. The name of an extensive genus of insects.

Gryllus verrucivorus. The wart-eating grasshopper. It has green wings, spotted with brown, and is caught by the common people in Sweden to destroy warts, which they do, by biting off the excrescence and discharging a corrosive liquor on the wound.

GRYPHO′SIS. (From γρυποω, to incurvate.) A disease of the nails, which turn inwards, and irritate the soft parts below.

GUAI′ACUM. (From the Spanish *Guayacan*, which is formed from the Indian *Hoaxacum.*) 1. The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order, *Monogynia*.

2. The pharmacopœial name of the officinal guaiacum. See *Guaiacum officinale.*

Guaiacum officinale. This tree, *Guaiacum—foliis bijugis, obtusis* of Linnæus, is a native of the West Indian islands. The wood, gum, bark, fruit, and even the flowers, have been found to possess medicinal qualities. The wood, which is called *Guaiacum Americanum; Lignum vitæ; Lignum sanctum; Lignum benedictum; Palus sanctus*, is brought principally from Jamaica, in large pieces of four or five hundred weight each, and from its hardness and beauty is used for various articles of turnery ware. It scarcely discovers any smell, unless heated, or while rasping, in which circumstances it yields a light aromatic one: chewed, it impresses a slight acrimony, biting the palate and fauces. The gum, or rather resin, is obtained by wounding the bark in different parts of the body of the tree, or by what has been called jagging. It exudes copiously from the wounds, though gradually; and when a quantity is found accumulated upon the several wounded trees, hardened by exposure to the sun, it is gathered and packed up in small kegs for exportation: it is of a friable texture, of a deep greenish colour, and sometimes of a reddish hue; it has a pungent acrid taste, but little or no smell, unless heated. The *bark* contains less resinous matter than the wood, and is consequently a less powerful medicine, though in a recent state it is strongly cathartic. "The *fruit*," says a late author, "is purgative, and, for medicinal use, far excels the bark. A decoction of it has been known to cure the venereal disease, and even the yaws in its advanced stage, without the use of mercury." The *flowers* or blossoms, are laxative, and in Jamaica are commonly given to the children in the form of syrup. It is only the wood and resin of guaiacum which are now in general medicinal use in Europe; and as the efficacy of the former is supposed to be derived merely from the quantity of resinous matter which it contains, they may be considered indiscriminately as the same medicine. Guaiacum was first introduced into the materia medica soon after the discovery of America; and previous to the use of mercury in the lues venerea, it was the principal remedy employed in the cure of that disease: its great success brought it into such repute, that it is said to have been sold for seven gold crowns a pound: but notwithstanding the very numerous testimonies in its favour, it often failed in curing the patient, and was at length entirely superseded by mercury; and though it be still occasionally employed in syphilis, it is rather with a view to correct other diseases in the habit, than for its effects as an anti-venereal. It is now more generally employed for its virtues in curing gouty and rheumatic pains, and some cutaneous diseases. Dr. Woodville and others frequently conjoined it with mercury and soap, and in some cases with bark or steel, and found it eminently useful as an alterative. In the Pharmacopœia it is directed in the form of mixture and tincture: the latter is ordered to be prepared in two ways, *viz.* with rectified spirit, and the aromatic spirit of ammonia. Of these latter compounds, the dose may be from two scruples to two drachms; the gum is generally given from six grains to 20, or even more, for a dose, either in pills or in a fluid form, by means of mucilage or the yolk of an egg. The decoctum lignorum (Pharm. Edinb.) of which guaiacum is the chief ingredient, is commonly taken in the quantity of a pint a day.

As many writers of the sixteenth century contended that guaiacum was a true specific for the venereal disease, and the celebrated Boerhaave maintained the same opinion, the following observations are inserted: Mr. Pearson mentions, that when he was first intrusted with the care of the Lock Hospital, 1781, Mr. Bromfield and Mr. Williams were in the habit of reposing great confidence in the efficacy of a decoction of guaiacum wood. This was administered to such patients as had already employed the usual quantity of mercury; but who complained of nocturnal pains, or had gummata, nodes, ozæna, and other effects of the venereal virus, connected with secondary symptoms, as did not yield to a course of mercurial frictions. The diet consisted of raisins and hard biscuit; from 2 to 4 pints of the decoction were taken every day; the hot bath was used twice a week; and a dose of antimonial wine and laudanum, or Dover's powder, was commonly taken every evening. Constant confinement to bed was not deemed necessary; neither was exposure to the vapour of burning spirit, with a view of exciting perspiration, often practised; as only a moist state of the skin was desired. This treatment was sometimes of singular advantage to those whose health had sustained injury from the disease, long confinement, and mercury. The strength increased; bad ulcers healed; exfoliations were completed; and these anomalous symptoms, which would have been exasperated by mercury, soon yielded to guaiacum.

Besides such cases, in which the good effects of guaiacum made it be erroneously regarded as a specific for the lues venera, the medicine was also formerly given, by some, on the first attack of the venereal disease. The disorder being thus benefited, a radical cure was considered to be accomplished: and though frequent relapses followed, yet, as these partly yielded to the same remedy, its reputation was still kept up. Many diseases also, which got well, were probably not venereal cases. Pearson seems to allow, that in syphilitic affections, it may indeed operate like a true antidote, suspending, for a time, the progress of certain venereal symptoms, and removing other appearances altogether; but he observes that experience has evinced, that the unsubdued virus yet remains active in the constitution.

Pearson has found guaiacum of little use in pains of the bones, except when it proved sudorific; but that it was then inferior to antimony or volatile alkali. When the constitution has been impaired by mercury and long confinement, and there is a thickened state of the ligaments, or periosteum, or foul ulcers still remaining, Pearson says, these effects will often subside during the exhibition of the decoction; and it will often suspend, for a short time, the progress of certain secondary symptoms of the lues venerea; for instance, ulcers of the tonsils, venereal eruptions, and even nodes. Pearson, however, never knew one instance in which guaiacum eradicated the virus; and he contends, that its being conjoined with mercury neither increases the virtue of this mineral, lessens its bad effects, nor diminishes the necessity of giving a certain quantity of it. Pearson remarks that he has seen guaiacum produce good effects in many patients, having cutaneous diseases, the ozæna, and scrofulous affections of the membranes and ligaments.

GUILA'NDINA. (Named after Guilandus, a Prussian, who travelled in Palestine, Egypt, Africa, and Greece, and succeeded Fallopius in the botanical chair at Padua. He died in 1589.) The name of a genus of plants. Class, *Decandria*; Order, *Monogynia*.

GUILANDINA BONDUC. The systematic name of the plant, the fruit of which is called *Bonduch indorum.* Molucca or bezoar nut. It possesses warm, bitter, and carminative virtues.

GUILANDINA MORINGA. This plant, *Guilandina—inermis, foliis subpinnatis, foliolis inferioribus ternatis* of Linnæus, affords the bennut and the lignum nephriticum.

1. *Ben nux; Glans unguentaria; Balanus myrepsica; Coatis.* The oily acorn, or bennut. A whitish nut, about the size of a small filberd, of a roundish triangular shape, including a kernel of the same figure, covered with a white skin. They were formerly employed to remove obstructions of the primæ viæ. The oil afforded by simple pressure, is remarkable for its not growing rancid in keeping, or, at least, not until it has stood for a number of years; and on this account, it is used in extricating the aromatic principles of such odoriferous flowers as yield little or no essential oil in distillation. The unalterability of this oil would render it the most valuable substance for cerates, or liniments, were it sufficiently common. It is actually employed for this purpose in many parts of Italy.

2. *Lignum nephriticum.* Nephritic wood. It is brought from America in large, compact, ponderous pieces, without knots, the outer part of a whitish, or pale yellowish colour, the inner of a dark brown or red. When rasped, it gives out a faint aromatic smell. It is never used medicinally in this country, but stands high in reputation abroad, against difficulties of making urine, nephritic complaints, and most disorders of the kidneys and urinary passages.

GUINEA PEPPER. See *Capsicum annuum.*

Guinea-worm. See *Medinensis vena.*

GUINTERIUS, JOHN, was born in 1487, at Andernach, in Germany. He was of obscure birth, and his real name is said to have been Winther. He showed very early a great zeal for knowledge, and at the age of 12 went to Utrecht to study; but he had to struggle with great hardships, supported partly by his own industry, partly by the bounty of those who commiserated his situation. At length, having given striking proofs of his talents, he was appointed professor of Greek at Louvain. But his inclination being to medicine, he went to Paris in 1525; where he was made doctor five years after. He was appointed physician to the king, and practised there during several years; giving also lectures on anatomy. His reputation had reached the north of Europe; and he received the most advantageous offers to repair to the court of Denmark. But in 1537 he was compelled by the religious disturbances to retire into Germany. At Strasburgh he was received with honour by the magistrates, and had a chair assigned him by the faculty; he also practised very extensively and successfully; and at length letters of nobility were conferred upon him by the emperor. He lived, however, only twelve years to enjoy these honours, having died in 1574. His works are numerous, consisting partly of translations of the best ancient physicians, but principally of commentaries and illustrations of them.

GUM. I. *Gummi.* The mucilage of vegetables. It is usually transparent, more or less brittle when dry, though difficultly pulverable; of an insipid, or slightly saccharine taste; soluble in, or capable of combining with, water in all proportions, to which it gives a gluey adhesive consistence, in proportion as its quantity is greater. It is separable, or coagulates by the action of weak acids; it is insoluble in alkohol, and in oil; and capable of the acid fermentation, when diluted with water. The destructive action of fire causes it to emit much carbonic acid, and converts it into coal without exhibiting any flame. Distillation affords water, acid, a small quantity of oil, a small quantity of ammonia, and much coal.

These are the leading properties of gums, rightly so called; but the inaccurate custom of former times applied the term gum to all concrete vegetable juices, so that in common we hear of gum copal, gum sandarach, and other gums, which are either pure resins, or mixtures of resins with the vegetable mucilage.

The principal gums are, 1. The common gums, obtained from the plum, the peach, the cherry-tree, &c. 2. Gum arabic, which flows naturally from the acacia in Egypt, Arabia, and elsewhere. This forms a clear transparent mucilage with water. 3. Gum Seneca, or Senegal. It does not greatly differ from gum arabic: the pieces are larger and clearer; and it seems to communicate a higher degree of the adhesive quality to water. It is much used by calico printers and others. The first sort of gums are frequently sold by this name, but may be known by their darker colour. 4. Gum adragant or tragacanth. It is obtained from a small plant, a species of astragalus, growing in Syria, and other eastern parts. It comes to us in small white contorted pieces, resembling worms. It is usually dearer than other gums, and forms a thicker jelly with water.

Willis has found, that the root of the common blue-bell, *Hyacinthus non scriptus*, dried and powdered, affords a mucilage possessing all the qualities of that from gum arabic. The roots of the vernal squill, white, lily, and orchis, equally yield mucilage. Lord Dundonald has extracted a mucilage also from lichens.

Gums treated with nitric acid afford the saclactic, malic, and oxalic acids.

II. *Gingiva.* The very vascular and elastic substance that covers the alveolar arches of the upper and under jaws, and embraces the necks of the teeth.

Gum acacia. See *Acacia vera.*

Gum arabic. See *Acacia vera.*

Gum, elastic. See *Caoutchouc.*

GUM-BOIL. See *Parulis.*

GU'MMA. A strumous tumour on the periosteum of a bone.

GUMMI. (*Gummi, n. indeclin.*) See *Gum.*

GUMMI ACACIÆ. See *Acacia vera.*

GUMMI ACANTHINUM. See *Acacia vera.*

GUMMI ARABICUM. See *Acacia vera.*

GUMMI CARANNÆ. See *Caranna.*

GUMMI CERASORUM. The juices which exude from the bark of cherry-trees. It is very similar to gum-arabic, for which it may be substituted.

GUMMI CHIBOU. A spurious kind of gum elemi, but little used.

GUMMI COURBARIL. An epithet sometimes applied to the juice of the *Hymenæa courbaril.* See *Anime.*

GUMMI EUPHORBII. See *Euphorbia.*

GUMMI GALDA. See *Galda.*

GUMMI GAMBIENSE. See *Kino.*

GUMMI GUTTÆ. See *Stalagmitis.*

GUMMI HEDERÆ. See *Hedera helix.*

GUMMI JUNIPERINUM. See *Juniperus communis.*

GUMMI KIKEKUNEMALO. See *Kikekunemalo.*

GUMMI KINO. See *Kino.*

GUMMI LACCA. See *Lacca.*

GUMMI LAMAC. See *Acacia vera.*

GUMMI LUTEA. See *Botany Bay.*

GUMMI MYRRHA. See *Myrrha.*

GUMMI RUBRUM ASTRINGENS GAMBIENSE. See *Kino.*

GUMMI SAGAPENUM. See *Sagapenum.*

GUMMI SCORPIONIS. See *Acacia vera.*

GUMMI SENEGA. See *Acacia vera.*

GUMMI SENEGALENSE. See *Mimosa senegal.*

GUMMI SENICA. See *Acacia vera.*

GUMMI THEBAICUM. See *Acacia vera.*

GUMMI TRAGACANTHÆ. See *Astragalus.*

GUM-RE'SIN. *Gummi resina.* Gum-resins are the juices of plants that are mixed with resin, and an extractive matter, which has been taken for a gummy substance. They seldom flow naturally from plants, but are mostly extracted by incision in the form of white, yellow, or red fluids, which dry more or less quickly. Water, spirit of wine, wine or vinegar, dissolve them only in part according to the proportion they contain of resin or extract. Gum-resins may also be formed by art, by digesting the parts of vegetables containing the gum-resin in diluted alkohol, and then evaporating the solution. For this reason most tinctures contain gum-resin. The principal gum-resins employed medicinally are aloes, ammoniacum, asafœtida, galbanum, cambogia, guaiacum, myrrha, olibanum, opoponax, sagapenum, sarcocolla, scammonium, and styrax.

GUNDELIA. (The name given by Tournefort in honour of his companion and friend, Andrew Gundelscheimer, its discoverer, in the mountains of Armenia.) A genus of plants. Class, *Syngenesia*; Order, *Polygamia segregata.*

GUNDELIA TOURNIFORTII. The young shoots of this plant are eaten by the Indians, but the roots are emetic.

GU'TTA. (*Gutta, æ.* f.) 1. A drop. Drops are uncertain forms of administering medicines, and should never be trusted to. The shape of the bottle or of its mouth, from whence the drops fall, as well as the consistence of the fluid, occasion a considerable difference in the quantity administered. See *Minimum.*

2. A name of apoplexy, from a supposition that its cause was a drop of blood falling from the brain upon the heart.

GUTTA GAMBA. See *Stalagmitis.*

GUTTA NIGRA. The black drop, occasionally called the Lancashire, or the Cheshire drop. A secret preparation of opium said to be more active than the common tincture, and supposed to be less injurious, as seldom followed by headache.

GUTTA OPACA. A name for the cataract.

GUTTA SERENA. (So called by the Arabians.) See *Amaurosis.*

GUTTÆ ROSACEÆ. Red spots upon the face and nose.

GU'TTURAL. Belonging to the throat.

GUTTURAL ARTERY. The superior thyroideal artery. The first branch of the external carotid.

GYMNA'STIC. (*Gymnasticus; from* γυμνος, naked, performed by naked men in the public games.) This term is applied to a method of curing diseases by exercise, or that part of physic which treats of the rules that are to be observed in all sorts of exercises, for the preservation of health. This is said to have been invented by one Herodicus, born at Salymbra, a city of Thrace; or, as some say, at Leutini in Sicily. He was first master of an academy where young gentlemen came to learn warlike and manly exercises; and observing them to be very healthful on that account, he made exercise become an art in reference to the recovering of men out of diseases, as well as preserving them from them, and called it *Gymnastic,* which he made a great part of his practice. But Hippocrates, who was his scholar, blames him sometimes for his excesses with this view. And Plato exclaims against him with some warmth, for enjoining his patients to walk from Athens to Megara, which is about 25 miles, and to come home on foot as they went, as soon as ever they had but touched the walls of the city.

GYMNOCARPI. The second division in Persoon's arrangement of mushrooms, such as bear seeds embedded in an appropriate, dilated, exposed membrane, denominated *hymenium,* like *helvella,* in which that part is smooth and even; *boletus,* in which it is porous; and the vast genus *agaricus,* in which it consists of gills.

GYMNOSPERMIA. (From γυμνος, naked, and σπερμα, a seed.) The name of an order of the class *Didynamia,* of the sexual system of plants, embracing such as have added to the didynamial character, four naked seeds.

GYNÆ'CIA. (From γυνη, a woman.) The menses, and also the lochia.

GYNÆ'CIUM. (From γυνη, a woman.)

1. A seraglio.
2. The *pudendum muliebre.*
3. A name for *antimony.*

GYNÆCOMA'NIA. (From γυνη, a woman, and μανια, madness.) That species of insanity that arises from love.

GYNÆCOMY'STAX. (From νυνη, a woman, and μυςταξ, a beard.) The hairs on the female pudendum.

GYNÆCOMA'STON. (From γυνη, a woman, and μαςος, a breast.) An enormous increase of the breasts of women.

GYNANDRIA. (From γυνη, a woman, and ανηρ, a man, or husband.) The name of a class in the sexual system of plants. It contains those hermaphrodite flowers, the stamina of which grow upon the pistil, so that the male and female organs are united, and do not stand separate as in other hermaphrodite flowers.

GYPSATA. (From *gypsum,* a saline body consisting of sulphuric acid and lime.) Dr. Good denominates a species of purging *diarrhœa gypsata,* in which the digestions are liquid, serous, and compounded of earth of lime.

GYPSUM. A genus of minerals, composed of lime and sulphuric acid, containing, according to Jameson, two species: the prismatic and the axifrangible.

1. *Prismatic* gypsum, or *anhydrite,* has five sub-species: sparry anhydrite, scaly anhydrite, fibrous anhydrite, convoluted anhydrite, compact anhydrite. See *Anhydrite.*

2. *Axifrangible* gypsum contains six sub-species: sparry gypsum, foliated, compact, fibrous, scaly foliated, and earthy gypsum.

H.

HABE'NA. A bridle. A bandage for keeping the lips of wounds together, made in the form of a bridle.

HACUE. See *Gundelia tournefortii.*

HÆMAGO'GA. (From αιμα, blood, and αγω, to bring off.) Medicines which promote the menstrual and hæmorrhoidal discharges.

HÆMALO'PIA. (From αιμα, blood, and οπτομαι, to see.) A disease of the eyes, in which all things appear of a red colour. A variety of the *Pseudoblepsis imaginaria.*

HÆ'MALOPS. (From αιμα, blood, and ωψ, the face.) 1. A red or livid mark in the face or eye.

2. A blood-shot eye.

HÆMA'NTHUS. (From αιμα, blood, and ανθος, a flower, so called from its colour.) The blood-flower.

HÆMATE'MESIS. (From αιμα, blood, and εμεω, to vomit.) *Vomitus cruentus.* A vomiting of blood. A vomiting of blood is readily to be distinguished from a discharge from the lungs, by its being usually preceded by a sense of weight, pain, or anxiety in the region of the stomach; by its being unaccompanied by any cough; by the blood being discharged in a very considerable quantity; by its being of a dark colour, and somewhat grumous; and by its being mixed with the other contents of the stomach.

The disease may be occasioned by any thing received into the stomach, which stimulates it violently or wounds it; or may proceed from blows, bruises, or any other cause capable of exciting inflammation in this organ, or of determining too great a flow of blood to it; but it arises more usually as a symptom of some other disease (such as a suppression of the menstrual, or hæmorrhoidal flux, or obstructions in the liver, spleen, and other viscera) than as a primary affection. It is seldom so profuse as to destroy the patient suddenly, and the principal danger seems to arise, either from the great debility which repeated attacks of the complaint induce, or from the lodgment of blood in the intestines, which by becoming putrid might occasion some other disagreeable disorder.

This hæmorrhage, being usually rather of a passive character, does not admit of large evacuations. Where it arises, on the suppression of the menses, in young persons, and returns periodically, it may be useful to anticipate this by taking away a few ounces of blood; not neglecting proper means to help the function of the uterus. In moderate attacks, particularly where the bowels have been confined, the infusion of roses and sulphate of magnesia may be employed: if this should not check the bleeding the sulphuric acid may be exhibited more largely, or some of the more powerful astringents and tonics, as alum, tincture of muriate of iron, decoction of bark, or superacetate of lead. Where pain attends, opium should be given freely, taking care that the bowels be not constipated; and a blister to the epigastrium may be useful. If depending on scirrhous tumours, these must be attacked by mercury, hemlock, &c. In all cases the food should be light, and easy of digestion; but more nourishing as the patient is more exhausted.

HÆMATICA. The name of a class of diseases in Good's Nosology, of the sanguineous system. Its orders are, *Pyretica*, *Phlegotica*, *Exanthematica*, *Dysthetica*.

HÆMATIN. The colouring matter of logwood, and according to Chevreuil, a distinct vegetable substance. See *Hæmatoxylon*.

HÆMATI′TES. (From *αιμα*, blood: so named from its property of stopping blood, or from its colour.) *Lapis hæmatites*. An elegant iron ore called bloodstone. Finely levigated, and freed from the grosser parts by frequent washings with water, it has been long recommended in hæmorrhages, fluxes, uterine obstructions, &c. in doses of from one scruple to three or four.

HÆMATI′TINUS. (From *αιματιτης*, the bloodstone.) An epithet of a collyrium, in which was the bloodstone.

HÆMATOCE′LE. (From *αιμα*, blood, and *κηλη*, a tumour.) A swelling of the scrotum, or spermatic cord, proceeding from or caused by blood. The distinction of the different kinds of hæmatocele, though not usually made, is absolutely necessary toward rightly understanding the disease; the general idea, or conception of which, appears to Pott to be somewhat erroneous, and to have produced a prognostic which is ill founded and hasty. According to this eminent surgeon, the disease, properly called hæmatocele, is of four kinds; two of which have their seat within the tunica vaginalis testis; one within the albuginea; and the fourth in the tunica communis, or common cellular membrane, investing the spermatic vessels.

In the passing an instrument, in order to let out the water from an hydrocele of the vaginal coat, a vessel is sometimes wounded, which is of such size, as to tinge the fluid pretty deeply at the time of its running out; the orifice becoming close, when the water is all discharged, and a plaster being applied, the blood ceases to flow from thence, but insinuates itself partly into the cavity of the vaginal coat, and partly into the cells of the scrotum; making in the space of a few hours, a tumour nearly equal in size to the original hydrocele. This is one species.

It sometimes happens in tapping an hydrocele, that although the fluid discharged by that operation be perfectly clear and limpid, yet in a very short space of time (sometimes in a few hours,) the scrotum becomes as large as it was before, and palpably as full of a fluid. If a new puncture be now made, the discharge, instead of being limpid (as before,) is either pure blood or very bloody. This is another species; and, like the preceding, confined to the tunica vaginalis.

The whole vascular compages of the testicle is sometimes very much enlarged, and at the same time rendered so lax and loose, that the tumour produced thereby has, to the fingers of an examiner, very much the appearance of a swelling composed of a mere fluid, supposed to be somewhat thick, or viscid. This is in some measure a deception; but not totally so: the greater part of the tumefaction is caused by the loosened texture of the testes; but there is very frequently a quantity of extravasated blood also. If this be supposed to be an hydrocele, and pierced, the discharge will be mere blood. This is a third kind of hæmatocele; and very different, in all its circumstances, from the two preceding: the fluid is shed from the vessels of the glandular part of the testicle, and contained within the tunica albuginea.

The fourth consists in a rupture of, and an effusion of blood, from a branch of the spermatic vein, in its passage from the groin to the testicles. In which case, the extravasation is made into the tunica communis, or cellular membrane, investing the spermatic vessels.

Each of these species, Pott says, he has seen so distinctly, and perfectly, that he has not the smallest doubt concerning their existence, and of their difference from each other.

HÆMATO′CHYSIS. (From *αιμα*, blood, and *χεω*, to pour out.) A hæmorrhage or flux of blood.

HÆMATO′DES. (From *αιμα*, blood, and *ειδος*, appearance: so called from the red colour.) 1. An old name for the bloody crane's-bill. See *Geranium sanguineum*.

2. A fungus, which has somewhat the appearance of blood. See *Hæmatoma*.

HÆMATO′LOGY. (*Hæmatologia*; from *αιμα*, blood, and *λογος*, a discourse.) The doctrine of the blood.

HÆMATOMA. (From *αιμα*, blood.) *Fungus hæmatodes*. The bleeding fungus. Spongoid inflammation of Burns. This disease has been described also under the names of soft cancer and medullary sarcoma. It assumes a variety of forms, and attacks most parts of the body, but particularly the testicle, eye, breast, and the extremities. It begins with a soft enlargement or tumour of the part, which is extremely elastic, and in some cases very painful; as it increases, it often has the feel of an encysted tumour, and at length becomes irregular, bulging out here and there, and insinuates itself between the neighbouring parts, and forms a large mass, if under an aponeurotic expansion. When it ulcerates it bleeds, shoots up a mass of a bloody fungus, and then shows its decided character if unknown before. Most of the medicines which have been employed against cancerous diseases have been unprofitably exhibited against hæmatoma; as alteratives, both vegetable and mineral; tonics and narcotics. Extirpation, when practicable, is the only cure.

HÆMATOMPHALOCE′LE. (From *αιμα*, blood, *ομφαλος*, the navel, and *κηλη*, a tumour.) A tumour about the navel, from an extravasation of blood. A species of ecchymosis.

HÆMATOPEDE′SIS. (From *αιμα*, blood, and *ϖεδαω*, a leap.) The leaping of the blood from a wounded artery.

HÆMATO′SIS. (From *αιμα*, blood.) An hæmorrhage or flux of blood.

HÆMATO′XYLON. (From *αιμα*, blood, and *ξυλον*, wood: so called from the red colour of its wood.) The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order, *Monogynia*.

HÆMATOXYLON CAMPECHIANUM. The systematic name of the logwood-tree. *Acacia Zeylonica*. The part ordered in the Pharmacopœia, is the wood, called *Hæmatoxyli lignum*;

Lignum campechense; Lignum campechianum; Lignum campescanum; Lignum indicum; Lignum sappan. Logwood. It is of a solid texture and of a dark red colour. It is imported principally as a substance for dyeing, cut into junks and logs of about three feet in length; of these pieces the largest and thickest are preserved, as being of the deepest colour. Logwood has a sweetish sub-adstringent taste, and no remarkable smell; it gives a purplish red tincture both to watery and spirituous infusions, and tinges the stools, and sometimes the urine, of the same colour. It is employed medicinally as an adstringent and corroborant. In diarrhœas it has been found peculiarly efficacious, and has the recommendation of some of the first medical authorities; also in the latter stages of dysentery, when the obstructing causes are removed; to obviate the extreme laxity of the intestines usually superinduced by the repeated dejections. In the form of decoction the proportion is two ounces to 2 ℔. of fluid, reduced by boiling to one. An extract is ordered in the pharmacopœias. The dose from ten to forty grains. The colouring principle of this root is called *hemetin.* On the watery extract of logwood, digest alkohol for a day, filter the solution, evaporate, add a little water, evaporate gently again, and then leave the liquid at rest. Hematin is deposited in small crystals, which, after washing with alkohol, are brilliant, and of a reddish-white colour. Their taste is bitter, acrid, and slightly astringent.

Hematin forms an orange-red solution with boiling water, becoming yellow as it cools, but recovering, with increase of heat, its former hue. Excess of alkali converts it first to purple, then to violet, and, lastly, to brown: in which state the hematin seems to be decomposed. Metallic oxides unite with hematin, forming a blue-coloured compound. Gelatin throws down reddish flocculi. Peroxide of tin, and acid, merely redden it.

HÆMATO'XYLUM. See *Hæmatoxylon.*

HÆMATU'RIA. (From *αιμα*, blood, and *ουρον*, urine.) The voiding of blood with urine. This disease is sometimes occasioned by falls, blows, bruises, or some violent exertion, such as hard riding and jumping; but it more usually arises, from a small stone lodged either in the kidney or ureter, which by its size or irregularity wounds the inner surface of the part it comes in contact with; in which case the blood discharged is most usually somewhat coagulated, and the urine deposits a sediment of a dark brown colour, resembling the grounds of coffee.

A discharge of blood by urine, when proceeding from the kidney or ureter, is commonly attended with an acute pain in the back, and some difficulty of making water, the urine which comes away first, being muddy and high coloured, but towards the close of its flowing, becoming transparent and of a natural appearance. When the blood comes immediately from the bladder, it is usually accompanied with a sense of heat and pain at the bottom of the belly.

The voiding of bloody urine is always attended with some danger, particularly when mixed with purulent matter. When it arises in the course of any malignant disease, it shows a highly putrid state of the blood, and always indicates a fatal termination.

The appearances to be observed on dissection will accord with those usually met with in the disease which has given rise to the complaint.

When the disease has resulted from a mechanical injury in a plethoric habit, it may be proper to take blood, and pursue the general antiphlogistic plan, opening the bowels occasionally with castor oil, &c. When owing to calculi, which cannot be removed, we must be chiefly content with palliative measures, giving alkalies or acids according to the quality of the urine; likewise mucilaginous drinks and glysters; and opium, fomentations, &c. to relieve pain; uva ursi also has been found useful under these circumstances; but more decidedly where the hæmorrhage is purely passive; in which case also some of the terebinthate remedies may be cautiously tried; and means of strengthening the constitution must not be neglected.

HÆMO'DIA. (From *αιμωδεω*, to stupefy.) A painful stupor of the teeth, caused by acrid substances touching them.

HÆMO'PTOE. (From *αιμα*, blood, and *πτυω*, to spit up.) The spitting of blood. See *Hæmoptysis.*

HÆMO'PTYSIS. (From *αιμα*, blood, and *πτυω*, to spit.) *Hæmoptoe.* A spitting of blood. A genus of disease arranged by Cullen in the class *Pyrexiæ*, and order *Hæmorrhagiæ.* It is characterised by coughing up florid or frothy blood, preceded usually by heat or pain in the chest, irritation in the larynx, and a saltish taste in the mouth. There are five species of this disease:

1. *Hæmoptysis plethorica*, from fulness of the vessels.

2. *Hæmoptysis violenta*, from some external violence.

3. *Hæmoptysis phthisica*, from ulcers corroding the small vessels.

4. *Hæmoptysis calculosa*, from calculous matter in the lungs.

5. *Hæmoptysis vicaria*, from the suppression of some customary evacuation.

It is readily to be distinguished from hæmatemesis, as in this last, the blood is usually thrown out in considerable quantities; and is, moreover of a darker colour, more grumous and mixed with the other contents of the stomach; whereas blood proceeding from the lungs is usually in small quantity, of a florid colour, and mixed with a little frothy mucus only.

A spitting of blood arises most usually between the ages of sixteen and twenty-five, and may be occasioned by any violent exertion either in running, jumping, wrestling, singing loud, or blowing wind-instruments; as likewise by wounds, plethora, weak vessels, hectic fever, coughs, irregular living, excessive drinking, or a suppression of some accustomed discharge, such as the menstrual or hæmorrhoidal. It may likewise be occasioned by breathing air which is too much rarefied to be able properly to expand the lungs.

Persons in whom there is a faulty proportion, either in the vessels of the lungs, or in the capacity of the chest, being distinguished by a narrow thorax and prominent shoulders, or who are of a delicate make and sanguine temperament, seem much predisposed to this hæmorrhage; but in these, the complaint is often brought on by the concurrence of the various occasional and exciting causes before mentioned.

A spitting of blood is not, however, always to be considered as a primary disease. It is often only a symptom, and in some disorders, such as pleurisies, peripneumonies, and many fevers, often arises, and is the presage of a favourable termination.

Sometimes it is preceded, as has already been observed, by a sense of weight and oppression at the chest, a dry tickling cough, and some slight difficulty of breathing. Sometimes it is ushered in with shiverings, coldness at the extremities, pains in the back and loins, flatulency, costiveness, and lassitude. The blood which is spit up is generally thin, and of a florid red colour; but sometimes it is thick, and of a dark or blackish cast; nothing, however, can be inferred from this circumstance, but that the blood has lain a longer or shorter time in the breast, before it was discharged.

An hæmoptoe is not attended with danger, where no symptoms of phthisis pulmonalis have preceded or accompanied the hæmorrhage, or where it leaves behind no cough, dyspnœa, or other affection of the lungs; nor is it dangerous in a strong healthy person, of a sound constitution; but when it attacks persons of a weak lax fibre, and delicate habit, it may be difficult to remove it.

It seldom takes place to such a degree as to prove fatal at once; but when it does, the effusion is from some large vessel. The danger, therefore, will be in proportion as the discharge of blood comes from a large vessel, or a small one.

When the disease proves fatal, in consequence of the rupture of some large vessels, there is found, on dissection, a considerable quantity of clotted blood in the lungs, and there is usually more or less of an inflammatory appearance at the ruptured part. Where the disease terminates in pulmonary consumption, the same morbid appearances are to be met with as described under that particular head.

In this hæmorrhage, which is mostly of the active kind, the antiphlogistic regimen must be strictly observed; particularly avoiding heat, muscular exertion, and agitation of the mind; and restricting the patient to a light, cooling, vegetable diet. Acidulated drink will be useful to quench the thirst, without so much liquid being taken. Where the blood is discharged copiously, but no great quantity has been lost already, it will be proper to attempt to check it by bleeding freely, if the habit will allow: and sometimes, where there is pain in the chest, local evacuations and blisters may be useful. The bowels should be well cleared with some cooling saline cathartic, which may be given in the infusion of roses. Digitalis is also a proper remedy, particularly where the pulse is very quick, from its sedative influence on the heart and arteries. Antimonials in nauseating doses have sometimes an excellent effect, as well by checking the force of the circulation, as by promoting diaphoresis; calomel also might be added with advantage; and opium, or other narcotic, to relieve pain and quiet cough, which may perhaps keep up the bleeding. Emetics have, on some occasions, been successful; but they are not altogether free from danger. In protracted cases, internal astringents are given, as alum, kino, &c. but their effects are very precarious: the superacetate of lead, however, is perhaps the most powerful medicine, especially combined with opium, and should always be resorted to in alarming or obstinate cases, though as it is liable to occasion colic and paralysis, its use should not be indiscriminate; but it acts probably rather as a sedative than astringent. Sometimes the application of cold water to some sensible part of the body, producing a general refrigeration, will check the bleeding. When the discharge is stopped, great attention to regimen is still required, to obviate its return, with occasional evacuations: the exercise of swinging, riding in an easy carriage, or on a gentle horse, or especially sailing, may keep up a salutary determination of the blood to other parts: an occasional blister may be applied, where there are marks of local disease, or an issue or seton perhaps answer better. Should hæmoptysis occasionally exhibit rather the passive character, evacuations must be sparingly used, and tonic medicines will be proper, with a more nutritious diet.

HÆMORRHAGIA. (From αιμα, blood, and ῥηγνυμι, to break out.) A hæmorrhage, or flow of blood.

HÆMORRHA'GIÆ. Hæmorrhages, or fluxes of blood. The name of an order in the class *Pyrexiæ* of Cullen's Nosology is so called. It is characterised by pyrexia with a discharge of blood, without any external injury; the blood on venæsection exhibiting the buffy coat. The order *Hæmorrhagiæ* contains the following genera of diseases, viz. epistaxis hæmoptysis, (of which phthisis is represented as a sequel,) hæmorrhois and menorrhagia.

HÆMORRHOI'DAL. (*Hæmorrhoidalis;* the name of the vessels which are the seat of the hæmorrhoids or piles.) 1. Of or belonging to the hæmorrhoidal vessels.

2. The trivial name of some plants which were supposed to be efficacious against piles; as *Carduus hæmorrhoidales*, &c.

HÆMORRHOIDAL ARTERIES. *Arteriæ hæmorrhoidales.* The arteries of the rectum are so called: they are sometimes two, and at other times three in number. 1. The upper hæmorrhoidal artery, which is the great branch of the lower mesenteric continued into the pelvis. 2. The middle hæmorrhoidal, which sometimes comes off from the hypogastric artery, and very often from the pudical artery. It is sometimes wanting. 3. The lower or external hæmorrhoidal is almost always a branch of the pudical artery, or that artery, which goes to the penis.

HÆMORRHOIDAL VEINS. *Venæ Hæmorrhoidales.* These are two. 1. The external, which evacuates itself into the vena iliaca interna.

2. The internal, which conveys its blood into the vena portæ.

HÆMO'RRHOIS. (From αιμα, blood, and ρεω, to flow.) *Aimorrhois.* The piles. A genus of disease in the class *Pyrexiæ*, and order *Hæmorrhagiæ* of Cullen. They are certain excrescences or tumours arising about the verge of the anus, or the inferior part of the intestinum rectum; when they discharge blood, particularly upon the patient's going to stool, the disease is known by the name of *bleeding piles;* but when there is no discharge, it is called *blind piles.* The rectum, as well as the colon, is composed of several membranes connected to each other by an intervening cellular substance; and as the muscular fibres of this intestine always tend, by their contraction, to lessen its cavity, the internal membrane, which is very lax, forms itself into several rugæ, or folds. In this construction nature respects the use of the part, which occasionally gives passage to or allows the retention of the excrements, the hardness and bulk of which might produce considerable lacerations, if this intestine were not capable of dilatation. The arteries and veins subservient to this part are called hæmorrhoidal, and the blood that returns from hence is carried to the meseraic veins. The intestinum rectum is particularly subject to the hæmorrhoids, from its situation, structure, and use; for whilst the course of the blood is assisted in almost all the other veins of the body, by the distention of the adjacent muscles, and the pressure of the neighbouring parts, the blood in the hæmorrhoidal veins which is to ascend against the natural tendency of its own weight, is not only destitute of these assistances, but is impeded in its passage: for, first, the large excrements which lodge in this intestine dilate its sides, and the different resistances which they form there are so many impediments obstructing the return of the blood; not in the large veins, for they are placed along the external surface of the intestine, but in all the capillaries which enter into its composition. Secondly, as often as these large excrements, protruded by others, approached near the anus, their successive pressure upon the internal coats of the intestine, which they dilate, drives back the blood into the veins, and for so long suspends its course; the necessary consequence of which is, a distention of the veins in proportion to the quantity of blood that fills them. Thirdly, in every effort we make, either in going to stool, or upon any other occasion, the contraction of the abdominal muscles, and the diaphragm pressing the contents of the abdomen downwards, and these pressing upon the parts contained in the pelvis, another obstruction is thereby opposed, to the return of the blood, not only in the large veins, but also in the capillaries, which, being of too weak a texture to resist the impule of the blood that always tends to dilate them, may hereby become varicose.

The dilatation of all these vessels is the *primary cause* of the hæmorrhoids: for the internal coat of the intestine, and the clelular membrane which connects that to the muscular coat, are enlarged in proportion to the distention of the vessels of which they are composed. This distention not being equal in every part, produces separate tumours in the gut, or at the verge of the anus, which increases according as the venal blood is obstructed in them, or circulates there more slowly.

Whatever, then, is capable of retarding the course of the blood in the hæmorrhoidal veins, may occasion this disease. Thus, persons that are generally costive, who are accustomed to sit long at stool, and strain hard; pregnant women, or such as have had difficult labours; and likewise persons who have an obstruction in their liver, are for the most part afflicted with the piles; yet every one has not the hæmorrhoids, the different causes which are mentioned above being not common to all, or at least not having in all the same effects. When the hæmorrhoids are once formed, they seldom disappear entirely, and we may judge of those within the rectum by those which, being at the verge of the anus, are plainly to be seen. A small pile, that has been painful for some days, may cease to be so, and dry up; but the skin does not afterwards retain its former firmness, being more lax and wrinkled, like the empty skin of a grape. If this external pile swells and sinks again several times, we may perceive, after each return, the remains of each pile, though shrivelled and decayed, yet still left larger than before. The case is the same with those that are situated within the rectum; they may happen indeed never to return again, if the cause that produced them is removed; but it is probable that the excrements in passing out occasion a return of the swelling, to which the external ones are less liable: for the internal piles make a sort of knots or tumours in the intestine, which straightening the passage, the excrements in passing out, occasion irritations there that are more or less painful in proportion to the efforts which the person makes in going to stool; and it is thus these tumours become gradually larger. The hæmorrhoids are subject to many variations; they may become inflamed from the above irritations to which they are exposed, and this inflammation cannot always be removed by art. In some, the inflammation terminates in an abscess, which arises in the middle of the tumour, and degenerates into a fistula. These piles are very painful till the abscess is formed. In others, the inflammation terminates by induration of the hæmorrhoid, which remains in a manner scirrhous. These never lessen, but often grow larger. This scirrhous sometimes ulcerates, and continually discharges a sanies, which the patient perceives by stains on his shirt, and by its occasioning a very troublesome itching about the verge of the anus. These kinds of hæmorrhoids sometimes turn cancerous. There are some hæmorrhoids, and those of different sizes, which are covered with so fine a skin as frequently to admit blood to pass through. This fine skin is only the internal coat of the rectum, greatly attenuated by the varicose distention of its vessels. The hæmorrhage may proceed from two causes, namely, either from an excoriation produced by the hardness of the excrements, or from the rupture of the tumified vessels, which break by their too great distention. In some of these, the patient voids blood almost every time he goes to stool; in others not so constantly. We sometimes meet with men who have a periodical bleeding by the piles, not unlike the menses in women; and as this evacuation, if moderate, does not weaken the constitution, we may infer that it supplies some other evacuation which nature either ceases to carry on, or does not furnish in due quantity; and hence also we may explain why the suppression of this discharge, to which nature had been accustomed, is frequently attended with dangerous diseases. The hæmorrhoids are sometimes distended to that degree as to fill the rectum, so that if the excrements are at all hard they cannot pass. In this case the excrements force the hæmorrhoids out of the anus to procure a free passage, consequently the internal coat of the rectum, to which they are connected, yields to extension, and upon examining these patients immediately after having been at stool, a part of the internal coat of that gut is perceived. A difficulty will occur in the return of these, in proportion to their size, and as the verge of the anus is more or less contracted. If the bleeding piles come out in the same manner upon going to stool, it is then they void most blood, because the verge of the anus forms a kind of ligature above them. The treatment of this complaint will vary much, according to circumstances. When the loss of blood is considerable, we should endeavour to stop it by applying cold water, or ice; or some astringent, as a solution of alum, or sulphate of zinc: but a more certain way is making continued pressure on the part. At the same time internal astringents may be given; joined with opium, if much pain or irritation attend. Care must be taken, however, to avoid constipation; and in all cases patients find benefit from the steady use of some mild cathartic, procuring regular loose motions. Sulphur is mostly resorted to for this purpose; and especially in combination with supertartrate of potassa, tamarinds, &c. in the form of electuary, usually answers very well; likewise castor oil is an excellent remedy in these cases. Should the parts be much inflamed, leeches may be applied near the anus, and cold satunine lotions used; sometimes, however, fomenting with the decoction of poppy will give more relief; where symptomatic fever attends, the antiphlogistic regimen must be strictly observed, and besides clearing the bowels, antimonials may be given to promote diaphoresis. Where the tumours are considerable and flaccid, without inflammation, powerful astringent or even stimulant applications will be proper, together with similar internal medicines; and the part should be supported by a compress kept on by a proper bandage. An ointment of galls is often very useful, with opium, to relieve pain; and some of the liquor plumbi subacetatis may be farther added, if there be a tendency to inflammation. In these cases of relaxed piles of some standing, the copaiba frequently does much good, both applied locally and taken internally, usually keeping the bowels regular; also the celebrated Ward's paste, a medicine of which the active ingredient is black pepper. Sometimes where a large tumour has been formed by extravasated blood, subsequently become organised, permanent relief can only be obtained by extirpating this.

HÆMOSTA'SIA. (From *αιμα*, blood, and *ιςημι*, to stand.) A stagnation of blood.

HÆMOSTA'TICA. (From *αιμα*, blood, and *ςαω*, to stop.) Medicines which stop hæmorrhages. See *Styptics*.

HAEN, Anthony de, was born in Leyden in 1704, and became one of the distinguished pupils of the celebrated Boerhaave. After graduating at his native place, he settled at the Hague, where he practised with considerable reputation for nearly 20 years. Baron Van Swieten, being acquainted with the extent of his talents, invited him to Vienna, to assist in the plan of reform, which the empress had consented to support in the medical faculty of that capital. De Haen accordingly repaired thither in 1754, was made professor of the practice of medicine, and fully answered the expectations which had been formed of him. He undertook a system of clinical education, as the best method of forming good physicians: the result of this was the collection of a great number of valuable observations, which were published in successive volumes of a work, entitled, "Ratio Medendi in Nosocomio Practico," amounting ultimately to 16. He left also several other works, as On the Division of Fevers, &c. and died at the age of 72. He was generally an enemy to new opinions and innovations in practice, which led him into several controversies; particularly against variolous inoculation, and the use of poisonous plants in medicine; but he exhibited much learning and practical knowledge.

Hagiospe'rmum. (From *αγιος*, holy, and *σπερμα*, seed: so called from its reputed virtues.) Wormseed.

Hagio'xylum. (From *αγιος*, holy, and *ξυλον*, wood: so named because of its medical virtues.) Guaiacum.

HAIR. See *Capillus*.

Hala'tium. (From *αλς*, salt.) A clyster composed chiefly of salt.

Halberd-shaped leaf. See *Leaf*.

Halche'mia. (From *αλς*, salt, and *χεω*, to pour out.) The art of fusing salts.

Halelæ'um. (From *αλς*, salt, and *ελαιον*, oil.) A medicine composed of salt and oil.

Halica'cabum. (From *αλς*, the sea, and *κακαβος*, night shade: so called because it grows upon the banks of the sea.) See *Physalis alkekengi*.

Ha'limus. (From *αλιμος*, belonging to the sea.) The *Atriplex halimus* of Linnæus, or sea-purslain, said to be antispasmodic.

Halini'trum. (From *αλς*, the sea, and *νιτρον*, nitre.) Nitre, or rather rock salt.

HA'LITUS. (From *halito*, to breathe out.) A vapour.

HALLER, Albert, was born at Berne, where his father was an advocate, in 1709. He displayed at a very early age extraordinary marks of industry and talents. He was intended for the church, but having lost his father when only thirteen, he soon after determined upon the medical profession. Having studied a short time at Tubingen, he was attracted to Leyden by the reputation of Boerhaave, to whom he has expressed his obligations in the most affectionate terms; but he took his degree at the former place, when about seventeen years of age. He soon after visited England and France; then returning to his native country, first acquired a taste for botany, which he pursued with great zeal, making frequent excursions to the neighbouring mountains. He also composed a "Poem on the Alps," and other pieces, which were received with much applause. Having settled in his native city, about 1730, he began to give lectures on anatomy, but with indifferent success; and some detached pieces on anatomy and botany having gained him considerable reputation abroad, he was invited by George II., in 1736, to become professor in the university, which he had recently founded at Gottingen. He accepted this advantageous offer, and though his arrival was rendered melancholy by the loss of a beloved wife, from some accident which occurred in the journey, he commenced at once the duties of his office with great zeal; he encouraged the most industrious of his pupils to institute an experimental investigation on some part of the animal economy, affording them his assistance therein. He was likewise himself indefatigable in similar researches, during the seventeen years which he spent there, having in view a grand reform in physiology, which his writings ultimately effected, dissipating the metaphysical and chemical jargon, whereby it was before obscured. He procured the establishment of a botanic garden, an anatomical theatre, a school for surgery and for midwifery, with a lying-in hospital, and other useful institutions at that university. He received also many honourable testimonies of his fame, being chosen a member of the Royal Societies of Stockholm and London, made physician and counsellor to George II., and the Emperor conferred on him the title of Baron; which, however, he declined, as it would not have been esteemed in his native country. To this he returned in 1753, and during the remainder of his life, discharged various important public offices there. He ultimately received every testimony of the general estimation in which he was held; the learned societies of Europe, as well as several sovereigns, vying with each other in conferring honours upon him. His constitution was delicate, and impatience of pain or interruption to his studies, led him to use violent remedies when ill; however, by temperance and activity he reached an advanced age, having died towards the end of 1777. He was one of the most universally informed men in modern times. He spoke with equal facility the German, French, and Latin languages; and read all the other tongues of Europe except the Sclavonic; and there was scarcely any book of reputation, with which he was not acquainted. His own works were extremely numerous, on anatomy, physiology, pathology, surgery, botany, &c. besides his poems and political and religious publications. The principal are, 1. His large work on the Botany of Switzerland, in 3 vols. folio, with many plates; 2. Commentaries on Boerhaave's Lectures, 7 vols. octavo; 3. Elements of Physiology, 8 vols. quarto, a work of the greatest merit; 4. His "Bibliotheca," or Chronological Histories of Authors, with brief Analyses; 2 vols. quarto on Botany, two on Surgery, two on Anatomy, and four on the Practice of Medicine, displaying an immense body of research.

HALLUCINA′TIO. (From *hallucinor*, to err.) An erroneous imagination.

Halmyro′des. (From αλμυρος, salted.) A term applied to the humours; it means acrimonious. It is also applied to fevers which communicate such an itching sensation as is perceived from handling salt substances.

HA′LO. (From αλὸς, an area or circle.) The red circle surrounding the nipple, which becomes somewhat brown in old people, and is beset with many sebaceous glands.

Hama′lgama. See *Amalgam.*

HAMOSUS. Hooked. Applied to the bristly pubescence of seeds and plants; as the pericarpe of the *Arctium lappa;* the seeds of *Daucus muricatus*, and *Alisma cordifolia.*

HAMPSTEAD. A village near to London, where there is an excellent chalybeate water, not inferior to that of Tunbridge-wells in any respect, except being nearer to the metropolis.

HA′MULUS. (Diminutive of *hamus*, a hook.) A term in anatomy, applied to any hook-like process, as the hamulus of the pterygoid process of the sphenoid bone.

HA′MUS. A hook. A species of pubescence of plants formed of bristles, bent at their point into a hook; as in *Rumex tuberosus, Caucalis daucoides*, and *Galium aparine*, &c.

HAND. *Manus.* The hand is composed of the carpus or wrist, metacarpus, and fingers. The *arteries* of the hand are the palmary arch, and the digital arteries. The veins are the digital, the cephalic of the thumb, and the salvatella. The nerves are the cutaneus, externus, and internus.

Harde′sia. See *Lapis Hibernicus.*

HARE. See *Lepus timidus.*

HARE-LIP. *Lagocheilus; Lagostoma; Labium leporinum.* A fissure or longitudinal division of one or both lips. Children are frequently born with this kind of malformation, particularly of the upper lip. Sometimes the portions of the lip, which ought to be united, have a considerable space between them; in other instances they are not much apart. The cleft is occasionally double, there being a little lobe, or small portion of the lip, situated between the two fissures. Every species of the deformity has the same appellation of hare-lip, in consequence of the imagined resemblance which the part has to the upper lip of a hare.

The fissure commonly affects only the lip itself. In many cases, however, it extends along the bones of the palate, even as far as the uvula. Sometimes these bones are totally wanting; sometimes they are only divided by a fissure.

Such a malformation is always peculiarly afflicting. In its least degree, it constantly occasions considerable deformity; and when it is more marked, it frequently hinders infants from sucking, and makes it indispensable to nourish them by other means. When the lower lip alone is affected, which is more rarely the case, the child can neither retain its saliva, nor learn to speak, except with the greatest impediment. But when the fissure pervades the palate, the patient not only never articulates perfectly, but cannot masticate nor swallow, except with great difficulty, on account of the food readily getting up into the nose.

HARMO′NIA. (From αρω, to fit together.) Harmony. A species of synarthrosis, or immoveable connection of bones, in which bones are connected together by means of rough margins, not dentiform: in this manner most of the bones of the face are connected together.

HARMOTOME. See *Cross-stone.*

HARRIS, Walter, was born at Gloucester about the year 1651. He took the degree of bachelor of physic at Oxford, but having embraced the Roman Catholic religion, he was made doctor at some French University. He settled in London in 1676, and two years after, to evade the order that all Catholics should quit the metropolis, he publicly adopted the Protestant Faith. His practice rapidly augmented, and on the accession of William III. he was appointed his physician in ordinary. He died in 1725. His principal work "De Morbis Acutis Infantum," is said to have been published at the suggestion of the celebrated Sydenham: it passed through several editions. He left also a Treatise on the plague, and a collection of medical and surgical papers, which had been read before the College of Physicians.

HARROGATE. The villages of High and Low Harrogate are situate in the centre of the county of York, adjoining the town of Knaresborough. The whole of Harrogate, in particular, has long enjoyed considerable reputation, by possessing two kinds of very valuable springs; and, some years ago, the chalybeate was the only one that was used internally, whilst the sulphureous water was confined to external use. At present, however, the latter is employed largely as an internal medicine.

The sulphureous springs of Harrogate are four in number, of the same quality, though different in the degree of their powers. This water, when first taken up, appears perfectly clear and transparent, and sends forth a few air bubbles, but not in any quantity. It possesses a very strong sulphureous and fœtid smell, precisely like that of a damp rusty gun barrel, or bilge-water. To the taste it is bitter, nauseous, and strongly saline, which is soon borne without any disgust. In a few hours of exposure this water loses its transparency, and becomes somewhat pearly, and rather greenish to the eye; its sulphureous smell abates, and at last the sulphur is deposited in the form of a thin film, on the bottom and sides of the vessel in which it is kept. The volatile productions of this water show carbonic acid, sulphuretted hydrogen, and azotic gas.

The sensible effects which this water excites, are often a headache and giddiness on being first drunk, followed by a purgative operation, which is speedy and mild, without any attendant gripes; and this is the only apparent effect the exhibition of this water displays.

The diseases in which this water is used are numerous, particularly of the alimentary canal, and irregularly of the bilious secretions. Under this water the health, appetite, and spirits improve; and, from its opening effects, it cannot fail to be useful in the costive habit of hypochondriasis. But the highest recommendation of this water has been in cutaneous diseases, and for this purpose it is universally employed, both as an internal medicine, and an external application: in this united form, it is of particular service in the most obstinate and complicated forms of cutaneous affections; nor is it less so in states and symptoms supposed connected with worms, especially with the round worm and ascarides, when taken in such a dose as to prove a brisk purgative; and in the latter case also, when used as a clyster, the ascarides being chiefly confined to the rectum, and therefore within the reach of this form of medicine. From the union of the sulphureous and saline ingredients, the benefit of its use has been long established in hæmorrhoidal affections.

A course of Harrogate waters should be conducted so as to produce sensible effects on the bowels; half a pint taken in the morning, and repeated three or four times, will produce it, and its nauseating taste may be corrected by taking a dry biscuit, or a bit of coarse bread after it. The course must be continued, in obstinate cases, a period of some months, before a cure can be expected.

HARTFELL. The name of a place near Moffat, in Scotland. It has a mineral water which contains iron dissolved by the sulphuric acid, and is much celebrated in scrophulous affections, and cutaneous diseases. It is used no less as an external application, than drank internally. The effects of this water, at first, are some degree of drowsiness, vertigo, and pain in the head, which soon go off, and this may be hastened by a slight purge. It produces generally a flow of urine, and an increase of appetite. It has acquired much reputation also in old and languid ulcers, where the texture of the diseased part is very lax, and the discharge profuse and ill conditioned.

The dose of this water is more limited than that of most of the mineral springs which are used medicinally. It is of importance in all cases, and especially in delicate and irritable habits, to begin with a very small quantity, for an over-dose is apt to be very soon rejected by the stomach, or to occasion griping and disturbance in the intestinal canal; and it is never as a direct purgative that this water is intended to be employed. Few patients will bear more than an English pint in the course of the day; but this quantity may be long continued. It is often advisable to warm the water for delicate stomachs, and this may be done without occasioning any material change in its properties.

HARTLEY, David, was born in 1705, son of a clergyman in Yorkshire. He studied at Cambridge, and was intended for the church, but scruples about subscribing to the 39 Articles led him to change to the medical profession; for which his talents and benevolent disposition well qualified him. After practising in different parts of the country, he settled for some time in London, but finally went to Bath where he died in 1757. He published some tracts concerning the stone, especially in commendation of Mrs. Stephens' medicine, and appears to have been chiefly instrumental in procuring her a reward from Parliament; yet he is said to have died of the disease after taking above two hundred pounds of soap, the principal ingredient in that nostrum. Some other papers were also written by him: but the principal work, upon which his fame securely rests, is a metaphysical treatise, entitled "Observations on Man, his Frame, his Duty, and his Expectations." The doctrine of vibration, indeed, on which he explained sensation, is merely gratuitous; but his Disquisitions on the Power of Association, and other mental Phenomena, evince great subtlety and accuracy of research.

HARVEY, William, the illustrious discoverer of the circulation of the blood, was born at Folkstone in Kent, in 1578. After studying four years at Cambridge, he went abroad at the age of 19, visited France and Germany, and then fixed himself at Padua, which was the most celebrated medical school in Europe, where he was created Doctor in 1602. On returning to England he repeated his graduation at Cambridge, and settled in London: he became a Fellow of the College of Physicians in 1603, and soon after physician to St. Bartholomew's Hospital. In 1615, he was appointed Lecturer on Anatomy and Surgery to the College, which was probably the more immediate cause of the publication of his grand discovery. He appears to have withheld his opinions from the world, until reiterated experiment had confirmed them, and enabled him to prove the whole in detail, with every evidence of which the subject will admit. The promulgation of this important doctrine brought on him the most unjust opposition, some condemning it as an innovation, others pretending that it was known before; and he complained that his practice materially declined afterwards: however he had the satisfaction of living to see the truth fully established. He likewise received considerable marks of royal favour from James and Charles I., to whom he was appointed physician; and the latter particularly assisted his enquiries concerning generation, by the opportunity of dissecting numerous females of the deer kind in different stages of pregnancy. During the civil war, when he retired to Oxford, his house in London was pillaged, and many valuable papers, the result of several years labour, destroyed. He published his first work on the circulation in 1628, at Frankfort, as the best means of circulating his opinions throughout Europe; after which he found it necessary to write two "Exercitations" in refutation of his opponents. In 1651 he allowed his other great work, "De Generatione Animalium," to be made public, leading to the inference of the universal prevalence of oval generation. In the year following he had the gratification of seeing his bust in marble, with a suitable inscription recording his discoveries, placed in the hall of the College of Physicians by a vote of that body; and he was soon after chosen President, but declined the office on account of his age and infirmities. In return he presented to the College an elegantly furnished convocation room, and a museum filled with choice books and surgical instruments. He also gave up his paternal estate of 56 pounds per annum for the institution of an annual feast, at which a Latin oration should be spoken, in commemoration of the benefactors of the College, &c. He died in 1658. A splendid edition of his works was printed in 1766, by the College, in quarto, to which a Latin Life of the author was prefixed, written by Dr. Laurence.

HASTATUS. Spear or halberd-shaped. Applied to a triangular leaf, hollowed out at the base and sides, but with spreading lobes; as in *Rumex acetocella,* and *Solanum dulcamara.*

Hatchet-shaped. See *Dolabriformis.*

HAUYNE. A blue-coloured mineral found imbedded in the basalt rock of Albaco and Frescate, which Jameson thinks is allied to the azure stone.

Hay, camel's. See *Juncus odoratus.*

HEAD. See *Caput.*

HEARING. *Auditus.* "The hearing is a function intended to make known to us the vibratory motion of bodies.

Sound is to the hearing what light is to the sight. Sound is the result of an impression produced upon the ear by the vibratory motion impressed upon the atoms of the body by percussion, or any other cause. This word signifies also the vibratory motion itself. When the atoms of a body have been thus put in motion, they communicate it to the surrounding elastic bodies: these communicate it in the same manner, and so the vibratory motion is often continued to a great distance. In general, only elastic bodies are capable of producing and propagating sound; but for the most part solid bodies produce it, and the air is generally the medium by which it reaches the ear.

There are three things distinguished in sound, *intensity*, *tone*, and *timbre* or *expression*. The intensity of sound depends on the extent of the vibrations.

The tone depends on the number of vibrations which are produced in a given time, and, in this respect, sound is distinguished into *acute* and *grave*. The grave sound arises from a small number of vibrations, the acute from a great number.

The gravest sound which the ear is capable of perceiving, is formed of thirty-two vibrations in a second. The most acute sound is formed of twelve thousand vibrations in a second. Between these two limits are contained all the distinguishable sounds, that is, those sounds of which the ear can count the vibration. Noise differs from distinguishable sound in so much as the ear cannot distinguish the number of vibrations of which it is composed.

A distinguishable sound, composed of double the number of vibrations of another sound, is said to be its octave. There are intermediate sounds, between these two, which are seven in number, and which constitute the *diatonic scale* or gamut: they are designated by the names, *ut*, *re*, *mi*, *fa*, *sol*, *la*, *si*.

When a sonorous body is put in motion by percussion, there is at first heard a sound very distinct, more or less intense, more or less acute, &c., according as it may happen; this is the fundamental sound; but with a little attention other sounds can be perceived. These are called harmonic sounds. This can be easily perceived in touching the string of an instrument.

The *timbre*, or expression of sound, depends on the nature of the sonorous body.

Sound is propagated through all elastic bodies. Its rapidity is variable according to the body which propagates it. The rapidity of sound in the air is a thousand one hundred and thirty English feet. It is still more rapidly transmitted by water, stone, wood, &c. Sound loses its force in a direct proportion to the square of the distance; this happens at least in the air. It may also become more intense as it proceeds; as happens when it passes through very elastic bodies, such as metals, wood, condensed air, &c. All sorts of sounds are propagated with the same rapidity, without being confounded one with another.

It is generally supposed that sound is propagated in right lines, forming cones, analogous to those of light, with this essential difference, however, that, in sonorous cones, the atoms have only a motion of oscillation, whilst those of the cones of light have a real transitive motion.

When sound meets a body that prevents its passage, it is reflected in the same manner as light, its angle of reflection being equal to the angle of incidence. The form of the body which reflects sound has similar influence upon it. The slowness with which sound is propagated, produces certain phenomena, for which we can easily account. Such is the phenomenon of echo, of the mysterious chamber, &c.

Apparatus of Hearing.—There are in the apparatus of hearing a number of organs, which appear to concur in that function by their physical properties; and behind them, a nerve for the purpose of receiving and transmitting impressions.

The apparatus of hearing is composed of the outer, middle, and internal ear; and of the acoustic nerve.

The auricle collects the sonorous radiations, and directs them towards the meatus externus; in proportion as it is large, elastic, prominent from the head, and directed forward. Boerhaave supposed he had proved by calculation, that all the sonorous radiations (or pulsations) which fall upon the external face of the pinna, are, ultimately, directed to the auditory passage. This assertion is evidently erroneous, at least for those pinnæ in which the *antihelix* is more projecting than the *helix*. How could those rays arrive at the concha, which fall upon the posterior surface of the antihelix? The pinna is not indispensable to the hearing; for, both in men and in the animals, it may be removed without any inconvenience beyond a few days.

The *Meatus auditorius* transmits the sound in the same manner as any other conduit, partly by the air it contains, and partly by its parietes, until it arrives at the membrane of the tympanum. The hairs, and the cerumen with which it is provided at the entrance, are intended to prevent the introduction of sand, dust, insects, &c.

The *Membrane of the Tympanum*, receives the sound which has been transmitted by the meatus auditorius. In what circumstances is it stretched by the internal muscle of the malleus? Or when is it relaxed by the contraction of the anterior muscle of the malleus? —All our knowledge on this subject is merely conjectural. An opening made in this membrane does not much impair the faculty of hearing. As this membrane is dry, and elastic, it ought to transmit the sound very well, both to the air contained in the tympanum, and to the chain of little bones. The chorda tympani cannot fail to participate in the vibrations of the membrane, and transmit impressions to the brain. The contact of any foreign body upon the membrane is very painful, and a violent noise also gives great pain. The membrane of the tympanum may be torn, or even totally destroyed, without deranging the hearing in any sensible degree.

The *Cavity of the Tympanum* transmits the sounds from the external to the internal ear. The transmission of sound by the tympanum happens —1st, By the chain of bones which has a particular action upon the membrane of the *fenestra ovalis*. 2d, By the air which fills it, and which acts upon the whole petrous portion, but particularly upon the membranum of the *fenestra ovalis*. 3d, By its sides.

The *Eustachian Tube* renews the air in the tympanum; being destroyed, it is said to cause deafness.

The notion of its being capable of carrying sound to the internal ear is erroneous; there is nothing to support this assertion: it permits the air to pass in cases when the *tympanum* is struck by violent sounds, and it permits the renewal of that which fills the *tympanum*, and the mastoid cells. The air in the *tympanum* being much rarified, is very suitable for diminishing the intensity of the sounds it transmits.

The use of the *mastoid cells* is not well known; it is supposed that they help to augment the intensity of the sound that arises in the cavity. If they produce this effect it ought to be rather from the vibrations of the partitions which separate the cells than from the air which they contain. Sound may arrive in the *tympanum* by another way than the external meatus; the shocks received by the bones of the head are directed towards the temples, and perceived by the ear. It is well known that the movement of a watch is heard distinctly when it is placed in contact with the teeth.

We know little of the *functions* of the internal ear; we can only imagine that the sonorous vibrations are propagated in different modes, but principally by the membrane of the *fenestra ovalis*, by that of the *fenestra rotunda*, and by the internal partition of the *tympanum;* that the liquor of Cotunnius ought to suffer vibrations which are transmitted to the acoustic nerve. It may be conceived how necessary it is that this liquid should give way to those vibrations which are too intense, and which might injure this nerve. Possibly, in this case, it flows into the aqueducts of the *cochlea* and of the vestibule, which, in this respect, would have a great deal of analogy with the *Eustachian tube.*

The internal *gyri* of the *cochlea* ought to receive the vibrations principally by the membrane of the *fenestra ovalis;* the vestibule, by the chain of bones; the semicircular canals, by the sides of the *tympanum*, and perhaps by the mastoid cells, which frequently extend beyond the canals. But the aid which is given to the hearing by each separate part of the internal ear is totally unknown.

The osseo-membraneous partition, which separates the *cochlea* into two parts, has given rise to a hypothesis which no one now admits.

The impressions are received and transmitted to the brain by the *acoustic nerve;* the brain perceives them with more or less facility and exactness in different individuals. Many people have a false ear, which means that they do not distinguish sounds perfectly.

There is no explanation given of the action of the acoustic nerve and of the brain in hearing.

In order to be heard, sounds must be within certain limits of intensity. Too strong a sound hurts us, whilst one too weak produces no sensation. We can perceive a great number of sounds at once. Sounds, particularly appreciable sounds, combined, and succeeding each other in a certain manner, are a source of agreeable sensations. It is in such combinations, for the production of this effect, that music is employed. On the contrary, certain combinations of sound produce a disagreeable impression; the ear is hurt by very acute sounds. Sounds which are very intense, and very grave, hurt excessively the membrane of the *tympanum.* By the absence of the liquor of *Cotunnius*, the hearing is destroyed. When a sound has been of long duration, we still think we hear it, though it may have been some time discontinued.

We receive two impressions, though we perceive only one. It has been said that we use only one ear at once, but this notion is erroneous.

When the sound comes more directly to the one ear, it is in reality, distinguished with more facility by that one, than by the other: therefore in this case we employ only one ear; and when we listen with attention to a sound which we do not hear exactly, we place ourselves so that the rays may enter directly into the concha; but when it is necessary to determine the direction of the sound, that is, the point whence it proceeds, we are obliged to employ both ears, for it is only by comparing the intensity of the two impressions, that we are capable of deciding from whence the sound proceeds. Should we shut one ear perfectly close, and cause a slight noise to be made in a dark place, at a short distance, it would be utterly impossible to determine its direction; in using both ears this could be determined. In these cases the eye is of great use, for even in using both ears it is frequently impossible to tell in the dark from whence a sound comes. By the sound we may also estimate the distance of the body from which it proceeds: but in order to judge exactly in this respect we ought to be perfectly acquainted with the nature of the sound, for without this condition the estimation is always erroneous. The principle upon which we judge is, that an intense sound proceeds from a body which is near, whilst a feeble sound proceeds from a body at a distance: if it happen that an intense sound comes from a distant body whilst a feeble sound proceeds from a body which is near, we fall into acoustic errors. We are generally very subject to deception with regard to the point whence a sound comes: sight and reason are of great use in assisting our judgment.

The different degree of convergence, and divergence, of the sonorous rays, do not seem to have any influence on the hearing, neither are they modified in their course, except for the purpose of making them enter into the ear in greater quantity: it is to produce this effect that speaking trumpets are used for those who do not hear well. Sometimes it is necessary to diminish the intensity of sounds: in this case a soft and scarcely elastic body is placed in the external meatus."—*Magendie's Physiology.*

HEART. *Cor.* A hollow muscular viscus, situated in the cavity of the pericardium for the circulation of the blood. It is divided externally into a *base*, or its broad part; a *superior* and an *inferior surface*, and an *anterior* and *posterior* margin. Internally, it is divided into a *right* and *left ventricle.* The situation of the heart is oblique, not transverse; its base being placed on the right of the bodies of the vertebræ, and its apex obliquely to the sixth rib on the left side; so that the left ventricle is almost posterior, and the right anterior. Its inferior surface lies upon the diaphragm. There are two cavities adhering to the base of the heart, from their resemblance called *auricles.* The right auricle is a muscular sac, in which are four *apertures*, two of the venæ cavæ, an opening into the right ventricle, and the opening of the coronary vein. The left is a similar sac, in which there are five *apertures*, viz. those of the four pulmonary veins, and an opening into the left ventricle. The cavities in the heart are called *ventricles:* these are divided by a fleshy septum, called *septum cordis*, into a right and left. Each ventricle has two *orifices;* the one auricular, through which the blood enters, the other arterious, through which the blood passes out. These four orifices are supplied with *valves*, which are named from their resemblance; those at the arterious orifices are called the *semilunar;* those at the orifice of the right auricle, *tricuspid;* and those at the orifice of the left auricle, *mitral. The valve of Eustachius* is situated at the termination of the vena cava inferior, just within the auricle. The substance of the heart is muscular, its exterior fibres are longitudinal, its middle transverse, and its interior oblique. The internal superfices of the ventricles and auricles of the heart are invested with a strong and smooth membrane, which is extremely irritable. The vessels of the heart are divided into *common* and *proper.* The *common* are, 1. The *aorta*, which arises from the left ventricle. 2. The *pulmonary artery*, which originates from the right ventricle. 3. The four pulmonary veins, which terminate in the left auricle. 4. The two *venæ cavæ*, which evacuate themselves into the right auricle. The *proper vessels* are, 1. The *coronary arteries*, which arise from the aorta, and are distributed on the heart. 2.

The *coronary veins*, which return the blood into the right auricle. The *nerves* of the heart are branches of the eight and great intercostal pairs. The heart of the fœtus differs from that of the adult, in having a *foramen ovale*, through which the blood passes from the right auricle to the left.

Heart-shaped. See *Cordatus.*

HEART'S EASE. See *Viola tricolor.*

HEAT. See *Caloric.*

HEAT, ABSOLUTE. This term is applied to the whole quantity of caloric existing in a body in chemical union.

HEAT, ANIMAL. "An inert body which does not change its position, being placed among other bodies, very soon assumes the same temperature, on account of the tendency of caloric to an equilibrium. The body of man is very different: surrounded by bodies hotter than itself, it preserves its inferior temperature as long as life continues; being surrounded with bodies of a lower temperature, it maintains its temperature more elevated. There are, then, in the animal economy, two different and distinct properties, the one of producing heat, the other of producing cold. We will examine these two properties. Let us first see how heat is produced.

The respiration appears to be the principal, or at least the most evident source of animal heat. In fact, experience demonstrates that the heat of the blood increases nearly a degree in traversing the lungs; and as it is distributed to all the parts of the body from the lungs, it carries the heat every where into the organs: for we have also seen that the heat of the veins is less than that of the arteries.

This development of heat in the respiration appears, as we have already said, to proceed from the formation of carbonic acid, whether it takes place directly in the lungs, or happens afterwards in the arteries, or in the parenchyma of the organs. Some very good experiments of Lavoisier, and De Laplace, lead to this conclusion: they placed animals in a *calorimeter*, and compared the quantity of acid formed by the respiration, with the quantity of heat produced in a given time: except a very small proportion, the heat produced was that which would have been occasioned by the quantity of carbonic acid which was formed.

It has also been proved by the experiments of Brodie, Thillage, and Legallois, that if the respiration of an animal is incommoded, either by putting it in a fatiguing position, or in making it respire artificially, its temperature lowers, and the quantity of carbonic acid that it forms becomes less. In diseases when the respiration is accelerated, the heat increases, except in particular circumstances. The respiration is then a focus in which caloric is developed.

In considering for an instant only this source of heat in the economy, we see that the caloric must be distributed to the different parts of the body in an unequal manner; those farthest from the heart, those that receive least blood, or which cool more rapidly, must generally be colder than those that are differently disposed.

This difference partly exists. The extremities are colder than the trunk; sometimes they present only 89° or 91° F., and often much less, while the cavity of the thorax is about 104° F.: but the extremities have a considerable surface relative to their mass; they are farther from the heart, and receive less blood than most of the organs of the trunk.

On account of the extent of their surface and distance from the heart, the feet and hands would probably have a temperature still lower than that which is peculiar to them, if these parts did not receive a greater proportional quantity of blood. The same disposition exists for all the exterior organs that have a very large surface, as the nose, the pavilion of the ear, &c.: their temperature is also higher than their surface and distance from the heart would seem to indicate.

Notwithstanding the providence of nature, those parts that have large surfaces lose their caloric with greater facility; and they are not only habitually colder than the others, but their temperature often becomes very low: the temperature of the feet and hands in winter is often nearly as low as 32° F. It is on this account we expose them so willingly to the heat of our fires.

Among other means that we instinctively employ to remedy or prevent coldness, are motion, walking, running, leaping, which accelerate the circulation; pressure, shocks upon the skin, which attract a great quantity of blood into the tissue of this membrane. Another equally effective means consists in diminishing the surface in contact with the bodies that deprive us of caloric. Thus we bend the different parts of the limbs upon each other, we apply them forcibly to the trunk when the exterior temperature is very low. Children and weak persons often take this position when in bed. In this respect it would be very proper that young children should not be confined too much in their swathing clothes to prevent them from thus bending themselves.

Our clothes preserve the heat of our bodies; for the substance of which they are formed being bad conductors of caloric, they prevent that of the body from passing off.

According to what has been said, the combination of the oxygen of the air with the carbon of the blood is sufficient for the explanation of most of the phenomena presented by the production of animal heat; but there are several which, if real, could not be explained by this means. Authors worthy of credit have remarked that, in certain local diseases, the temperature of the diseased place rises several degrees above that of the blood, taken at the left auricle. If this is so, the continual renewal of the arterial blood is not sufficient to account for this increase of heat.

This second source of heat must belong to the nutritive phenomena which take place in the diseased part.

There is nothing forced in this supposition; for most of the chemical combinations produce elevations of temperature, and it cannot be doubted that both in the secretions and in the nutrition, combinations of this sort take place in the organs.

By means of these two sources of heat, life can be maintained though the external temperature is very low, as that of winter in the countries near the pole, which descends sometimes to —42° F. Generally such an excessive cold is not supported without great difficulty, and it often happens that the parts most easily cooled are mortified: many of the military suffered these accidents in the wars of Russia. Nevertheless, as we easily resist a temperature much lower than our own, it is evident that we are possessed of the faculty of producing heat to a great degree.

The faculty of producing cold, or, in more exact terms, of resisting foreign heat, which has a tendency to enter our organs, is more confined. In the torrid zone, it has happened that men have died suddenly when the temperature has approached 122° F.

But this property is not less real, though limited. Banks, Blagden, and Fordyce, having exposed themselves to a heat of nearly 260°, they found that their bodies had preserved nearly their own temperature. More recent experiments of Berger and Delaroche have shown that by this cause the heat of the body may rise several degrees: for this to take place it is only necessary that the surrounding temperature should be a little elevated. Having both placed themselves in a stove of 120°, their temperature rose nearly 6.8° F. Delaroche having remained sixteen minutes in a dry stove at 176°, his temperature rose 9° F.

Franklin, to whom the physical and moral sciences are indebted for many important discoveries, and a great many ingenious views, was the first who discovered the reason why the body thus resists such a strong heat. He showed that this effect was due to the evaporation of the cutaneous and pulmonary transpiration, and that in this respect the bodies of animals resemble the porous vases called *alcarrazas*. These vessels, which are used in hot countries, allow the water that they contain to sweat through them; their surface is always humid, and a rapid evaporation takes place which cools the liquid they contain.

In order to prove this important result, Delaroche placed animals in a hot atmosphere that was so saturated with humidity that no evaporation could take place. These animals could not support a heat but a little greater than their own without perishing, and they became heated, because they had no longer the means of cooling themselves. Thus, there is no doubt that the cutaneous and pulmonary evaporation are the cause which enables man and animals to resist a strong heat. This explanation is also confirmed by the considerable loss of weight that the body suffers after having been exposed to a great heat.

According to these facts it is evident that the authors who have represented animal heat as fixed, have been very far from the truth. To judge exactly of it, it would be necessary to take into account the surrounding temperature and humidity; the degree of heat of different parts ought to be considered, and the temperature of one part ought not to be determined by that of another.

We have few correct observations upon the temperature proper to the body of man; the latest are due to Edwards and Gentil. These authors observed that the most suitable place for judging of the heat of the body is the armpit. They noticed nearly 2½ degrees of difference between the heat of a young man and that of a young girl: the heat of her hand was a little less than 97¼°, that of the young man was 98.4°. The same person observed great differences of heat in the different temperaments. There are also diurnal variations; the temperature may change about two or three degrees from morning to evening."—*Ure's Chem. Dict.*

HEAT, FREE. If the heat which exists in any substance be from any cause forced in some degree to quit that substance, and to combine with those that surround it, then such heat is said to be free, or sensible, until the equilibrium is restored.

HEAT, LATENT. When any body is in equilibrium with the bodies which surround it with respect to its heat, that quantity which it contains is not perceptible by any external sign, or organ of sense, and is termed combined caloric, or latent heat.

Heat, sensible. See *Heat, free.*

Heavy carbonated hydrogen. See *Carburetted hydrogen.*

HEAVY SPAR. Baryte. A genus of minerals, divided by Professor Jameson into four species.

1. *Rhomboidal* baryte, or *Witherite.* This is a carbonate of barytes; and is found in Cumberland and Durham.

2. *Prismatic* baryte, or *heavy spar*, a sulphate; found also in Cumberland and Durham.

3. *Diprismatic baryte*, or *strontianite.* A carbonate of barytes; found in Strontian, in Argyleshire.

4. *Axifrangible baryte*, or *Celestine.* A sulphate of strontites, with about two per cent. of sulphate of barytes; found near Edinburgh, in Inverness-shire, and Bristol.

Heavy inflammable air. See *Carburetted hydrogen gas.*

HEBERDEN, WILLIAM, was born in London in 1710, and graduated at Cambridge, where he afterwards practised during ten years, and gave lectures on the Materia Medica. During this period he published a little Tract, entitled "Antitheriaca," condemning the complication of certain ancient Formulæ of Medicines. In 1748, he removed to London, having previously been elected a Fellow of the College of Physicians; and he was shortly after admitted into the Royal Society. He soon rose to considerable reputation and practice in his profession. At his suggestion "the Medical Transactions of the College of Physicians," first appeared in 1768; and four other volumes have since been published at different periods. Dr. Heberden contributed some valuable papers to this work, especially on the Angina Pectoris, a disease not before described; and on Chicken Pox, which he first accurately distinguished from Small Pox. Some other papers of his appeared in the Philosophical Transactions. As he advanced in years he began to relax from the fatigue of practice: and in 1782 he drew up the result of his experience in a volume of "Commentaries," written in Latin, the great excellence of which is its style. He reserved it for publication, however, till after his death, which did not happen till 1801.

HECTIC. (*Hecticus*; from εξις, habit.) See *Febris hectica.*

HE'DERA. (From *hæreo*, to stick, because it attaches itself to trees and old walls.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia.* The ivy.

HEDERA ARBOREA. See *Hedera helix.*

HEDERA HELIX. *Hedera arborea.* The ivy. The leaves of this tree have little or no smell, but a very nauseous taste. Haller informs us, that they are recommended in Germany against the atrophy of children. By the common people of this country they are sometimes applied to running sores, and to keep issues open. The berries were supposed by the ancients to have a purgative and emetic quality; and an extract was made from them by water, called by Quercetanus *extractum purgans.* Later writers have recommended them in small doses as alexipharmic and sudorific: it is said, that in the plague at London, the powder of them was given in vinegar, or white wine, with good success. It is from the stalk of this tree that a resinous juice, called *Gummi hederæ*, exudes very plentifully in warm climates. It is imported from the East Indies, though it may be collected from trees in this country. It is brought over in hard compact masses, externally of a reddish-brown colour, internally of a bright brownish yellow, with reddish specks or veins. It has a strong, resinous, agreeable smell, and an adstringent taste. Though never used in the practice of the present day, it possesses corroborant, astringent, and antispasmodic virtues.

HEDERA TERRESTRIS. See *Glecoma.*

HEDERACEÆ. (From *hedera*, the ivy.)

The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of the ivy and a few other genera which in their form and appearance resemble it.

Hedge hyssop. See *Gratiola officinalis.*

Hedge mustard. See *Erysimum officinale.*

Hedge mustard, stinking. See *Erysimum Alliaria.*

HE'DRA. 1. The anus.

2. Excrement.

3. A fracture.

HEDYO'SMOS. Mint.

HEISTER, LAURENCE, was born at Frankfort on the Maine in 1683. After studying in different German universities, and serving some time as an army-surgeon, he graduated at Leyden; and in 1709 was appointed physician general to the Dutch Military Hospital. The next year he became professor of anatomy and surgery at Altorf: and having distinguished himself greatly by his lectures and writings, he received in 1720 a more advantageous appointment at Helmstadt, under the Duke of Brunswick, as physician, Aulic counsellor, and professor of Medicine; in which he continued, notwithstanding an invitation to Russia from the Czar Peter, till the period of his death in 1758. He was author of several esteemed works, particularly a Compendium of Anatomy, which became very popular, being remarkable for its conciseness and clearness. His "Institutions of Surgery," also gained him great credit: being translated into Latin, and most of the modern languages of Europe. Another valuable practical work was entitled "Medical, Surgical, and Anatomical Cases and Observations." He had some taste for botany also, which he taught at Helmstadt, and considerably enriched the garden there; but he unfortunately became an antagonist of the celebrated Linnæus, not properly appreciating the excellence of the system of that eminent naturalist.

HELCO'MA. Ulceration.

HELCO'NIA. (From ελκος, an ulcer.) An ulcer in the external or internal superficies of the cornea, known by an excavation and oozing of purulent matter from the cornea.

HELCY'DRION. (From ελκος, an ulcer, and υδωρ, water.) *Helcydrium.* A moist ulcerous pustule.

HELCY'STER. (From ελκω, to draw.) An instrument for extracting the fœtus.

HELE'NIUM. (From *Helene*, the island where it grew.) See *Inula helenium.*

HELIANTHUS. (From ηλιος, the sun; and ανθος, a flower. This name originated from the resemblance which its broad golden disk and ray bear to the sun, and is rendered further appropriate by its having the power of constantly presenting its flowers to that luminary.) The name of a genus of plants. Class, *Syngenesia;* Order, *Polygamia frustranea.* The sun-flower.

HELIANTHUS ANNUUS. The systematic name of the *Corona solis*, and *chimalatus.* The seeds have been made into a nutritious bread. The whole plant when young is boiled and eaten in some countries, as being aphrodisiac.

HELIANTHUS TUBEROSUS. Jerusalem artichoke. Although formerly in estimation for the table, this root is now neglected, it being apt to produce flatulency and dyspepsia.

HELICA'LIS MAJOR. See *Helicis major.*

HELICA'LIS MINOR. See *Helicis minor.*

HE'LICIS MAJOR. A proper muscle of the ear, which depresses the part of the cartilage of the ear into which it is inserted; it lies upon the upper or sharp point of the helix, or outward ring, arising from the upper and acute part of the helix anteriorly, and passing to be inserted into its cartilage a little above the tragus.

HELICIS MINOR. A proper muscle of the ear, which contracts the fissure of the ear; it is situated below the helicis major, upon part of the helix. It arises from the inferior and anterior part of the helix, and is inserted into the crus of the helix, near the fissure in the cartilage opposite to the concha.

HELIOTROPE. A subspecies of rhomboidal quartz.

HELIOTROPIUM. (Ἡλιοτροπιον τω μεγα, of Dioscorides; from ηλιος, the sun, and τροπη, a turning or inclination; because, says that ancient writer, it turns its leaves round with the declining sun.) The name of a genus of plants. Class, *Pentandria;* Order, *Monogynia.*

HELIOTRO'PII SUCCUS. See *Croton tinctorium.*

HE'LIX. (Ελιξ, from ειλω, to turn about.) The external circle or border of the outer ear, that curls inwards.

HELIX HORTENSIS. The garden snail.

HELLEBORA'STER. (From ελλεβορος, hellebore.) See *Helleborus fœtidus.*

HELLEBORE. See *Helleborus.*

Hellebore black. See *Helleborus niger.*

Hellebore white. See *Veratrum album.*

HELLE'BORUS. (Ελλεβορος: παρα το τη βορα ελλειν, because it destroys, if eaten.) The name of a genus of plants in the Linnæan system. Class, *Polyandria;* Order, *Polygynia.* Hellebore.

HELLEBORUS ALBUS. See *Veratrum album.*

HELLEBORUS FŒTIDUS. Stinking hellebore, or bear's-foot. *Helleboraster. Helleborus—caule multifloro folioso, foliis pedatis,* of Linnæus. The leaves of this indigenous plant are recommended by many as possessing extraordinary anthelmintic powers. The smell of the recent plant is extremely fœtid, and the taste is bitter and remarkably acrid, insomuch that, when chewed, it excoriates the mouth and fauces. It commonly operates as a cathartic, sometimes as an emetic, and, in large doses, proves highly deleterious.

HELLEBORUS NIGER. Black hellebore, or Christmas rose. *Melampodium. Helleborus—scapo subbiflore subnudo, foliis pedatis* of Linnæus. The root of this exotic plant is the part employed medicinally: its taste, when fresh, is bitterish, and somewhat acrid: it also admits a nauseous acrid smell; but, being long kept, both its sensible qualities and medicinal activity suffer very considerable diminution. The ancients esteemed it as a powerful remedy in maniacal cases. At present it is exhibited principally as an alterative, or, when given in a large dose, as a purgative. It often proves a very powerful emmenagogue in plethoric habits, where steel is ineffectual, or improper. It is also recommended in dropsies, and some cutaneous diseases.

HELMET-FLOWER. See *Anthora.*

HELMI'NTHAGOGUE. (*Helminthagogus*, from ελμινς, a worm, and αγω, to drive out.) Whatever destroys and expels worms. See *Anthelmintic.*

HELMINTHIA. The name of a genus of diseases. Class, *Cœliaca;* Order, *Enterica*, in Good's Nosology. Invermination, worms. It has three species, viz. *Helminthia alvi, podicis, erratica.*

HELMINTHI'ASIS. (Ελμινθιασις; from ελμινς, which signifies any species of worm.) A disease in which worms, or the larvæ of worms, are bred under the skin, or some external part of the body. It is endemial to Martinique, Westphalia, Transylvania, and some other places.

HELMINTHOCO'RTON. See *Corallina corsicana.*

HELMONT, John Baptist Van, was born of a noble family at Brussels in 1577. He exhibited very early proofs of superior abilities, and soon became convinced how much hypothesis was ranked under the name of science and philosophy in books; he seems to have perceived the necessity of experiment and induction in the discovery of real knowledge; but did not methodize his ideas sufficiently, to pursue that plan with its full advantage. After taking his degree at Louvain he travelled during ten years, and in this period acquired some practical knowledge of chemistry. On his return in 1609 he married a noble lady of large fortune, which enabled him to pursue his researches into the three kingdoms of nature with little interruption. He declined visiting patients, but gave gratuitous advice to those who went to consult him; and he boasts of having cured several thousands annually. He continued his investigations with astonishing diligence during thirty years, and made several discoveries in chemistry; among which were certain articles possessed of considerable activity on the human body. This confirmed his opposition to the Galenical school, the absurd hypotheses, and inert practice of which he attacked with great warmth and ability. Indeed he contributed greatly to overturn their influence; but from a desire to explain every thing on chemical principles, he substituted doctrines equally gratuitous or unintelligible. He published various works from time to time, which brought him considerable reputation, and he was repeatedly invited to Vienna; but he preferred continuing in his laboratory. He died in 1644.

HELO'DES. (From ελος, a marsh.) A term applied to fevers generated from marsh miasma.

HELO'SIS. (From ειλω, to turn.) An eversion or turning up of the eyelids.

HELVINE. A sub-species of dodecahedral garnet.

He'lxines. (From ελκω, to draw: so called because it sticks to whatever it touches.) Pellitory of the wall.

Hemalo'pia. Corruptly written for hæmalopia.

HEMATIN. The colouring principle of logwood. See *Hæmatoxylon campechianum.*

HEMATU'RIA. See *Hæmaturia.*

HEMERALO'PIA. (From ημερα, the day, and ωφ, the eye.) A defect in the sight, which consists in being able to see in the day-time, but not in the evening. The following is Scarpa's description of this curious disorder. Hemarolopia, or *nocturnal blindness*, is properly nothing but a kind of imperfect periodical amaurosis, most commonly sympathetic with the stomach. Its paroxysms come on towards the evening, and disappear in the morning. The disease is endemic in some countries, and epidemic, at certain seasons of the year, in others. At sun-set, objects appear to persons affected with this complaint as if covered with an ash-coloured veil, which gradually changes into a dense cloud, which intervenes between the eyes and surrounding objects. Patients with hemeralopia, have the pupil, both in the day and night-time, more dilated, and less moveable than it usually is in healthy eyes. The majority of them, however, have the pupil more or less moveable in the day-time, and always expanded and motionless at night. When brought into a room faintly lighted by a candle, where all the bystanders can see tolerably well, they cannot discern at all, or in a very feeble manner, scarcely any one object; or they only find themselves able to distinguish light from darkness, and at moon-light their sight is still worse. At day-break they recover their sight, which continues perfect all the rest of the day till sun-set.

HEMERALOPS. (From ημερα, the day, and ωφ, the eye.) One who can see but in the day-time.

Hemicerau'nios. (From ημισυς, half, and κειρω, to cut: so called because it was cut half way down.) A bandage for the back and breast.

HEMICRA'NIA. (From ἥμισυς, half, and κοανιόν, the head.) A pain that affects only one side of the head. It is generally nervous or hysterical, sometimes bilious; and in both cases sometimes comes at a regular period, like an ague. When it is accompanied by a strong pulsation like that of a nail piercing the part, it is denominated *clavus.*

HEMIO'PSIA. (From ημισυς, half, and ωψ, an eye.) A defect of vision, in which the person sees the half, but not the whole of an object.

Hemipa'gia. (From ημισυς, half, and παγιος, fixed.) A fixed pain on one side of the head. See *Hemicrania.*

HEMIPLE'GIA. (From ημισυς, half, and πλησσω, to strike.) A paralytic affection of one side of the body. See *Paralysis.*

HEMLOCK. See *Conium maculatum.*

HEMLOCK-DROPWORT. See *Œnanthe crocata.*

Hemlock, water. See *Cicuta virosa.*

Hemorrhage from the lungs. See *Hæmoptysis.*

Hemorrhage from the nose. See *Epistaxis.*

Hemorrhage from the stomach. See *Hæmatemesis.*

Hemorrhage from the urinary organs. See *Hæmaturia.*

Hemorrhage from the uterus. See *Menorrhagia.*

HEMP. See *Cannabis.*

HEMP-AGRIMONY. See *Eupatorium cannibanum.*

Hemp, water. See *Eupatorium.*

HENBANE. See *Hyoscyamus.*

HE'PAR. (*Hepar, atis.* n. Ηπαρ, the liver.) See *Liver.*

Hepar sulphuris. Liver of sulphur. A sulphuret made either with potassa or soda. See *Sulphuretum potassæ.*

Hepar uterinum. The placenta.

HEPATA'LGIA. (From ηπαρ, the liver, and αλγος, pain.) Pain in the liver.

HEPATIC. (*Hepaticus;* from ηπαρ, the liver.) Belonging to the liver.

Hepatic air. See *Hydrogen sulphuretted.*

Hepatic artery. *Arteria hepatica.* The artery which nourishes the substance of the liver. It arises from the cœliac, where it almost touches the point of the *lobulus Spigelii.* Its root is covered by the pancreas; it then turns a little forwards, and passes under the pylorus to the porta of the liver, and runs betwixt the biliary ducts and the vena portæ, where it divides into two large branches, one of which enters the right, and the other the left lobe of the liver. In this place it is enclosed along with all the other vessels in the capsule of Glisson.

Hepatic duct. *Ductus hepaticus.* The trunk of the biliary pores. It runs from the sinus of the liver towards the duodenum, and is joined by the cystic duct, to form the ductus communis choledochus. See *Biliary duct.*

Hepatic veins. See *Vein*, and *Vena portæ.*

Hepatica. (From ἡπαρ, the liver: so called because it was thought to be useful in diseases of the liver.) See *Marchantia polymorpha.*

Hepatica nobilis. See *Anemone hepatica.*

Hepatica terrestris. See *Marchantia polymorpha.*

HEPATIRRHŒ'A. (From ηπαρ, the liver, and ρεω, to flow.) 1. A purging with bilious evacuations.

2. A diarrhœa, in which portions of flesh, like liver, are voided.

HEPATITE. Fœtid, straight, lamellar, heavy spar. A variety of lamellar barytes, containing a small quantity of sulphur, in consequence of which, when it is heated or rubbed, it emits a fœtid sulphureous odour.

HEPATI'TIS. (From ηπαρ, the liver.) *Inflammatio hepatis.* An inflammation of the liver. A genus of disease in the class *Pyrexiæ*, and order *Phlegmasiæ* of Cullen, who defines it "febrile affection, attended with tension and pain of the right hypochondrium, often pungent, like that of a pleurisy, but more frequently dull, or obtuse, a pain at the clavicle and at the top of the shoulder of the right side; much uneasiness in lying down on the left side; difficulty of breathing; a dry cough, vomiting, and hiccup."

Besides the causes producing other inflammations, such as the application of cold, external injuries from contusions, blows, &c. this disease may be occasioned by certain passions of the mind, by violent exercise, by intense summer heats, by long continued intermittent and remittent fevers, and by various solid concretions in the substance of the liver. In warm climates this viscus is more apt to be affected with inflammation than perhaps any other part of the body, probably from the increased secretion of bile which takes place when the blood is thrown on the internal parts, by an exposure to cold; or from the bile becoming acrid, and thereby exciting an irritation in the part. Hepatitis has generally been considered of two kinds; one the *acute*, the other *chronic.*

The *acute* species of hepatitis comes on with a pain in the right hypochondrium, extending up to the clavicle and shoulder; which is much increased by pressing upon the part, and is accompanied with a cough, oppression of breathing, and difficulty of lying on the left side; together with nausea and sickness, and often with a vomiting of bilious matter. The urine is of a deep saffron colour, and small in quantity; there is loss of appetite, great thirst, and costiveness, with a strong, hard, and frequent pulse; and when the disease has continued for some days, the skin and eyes become tinged of a deep yellow. When the inflammation is in the cellular structure or substance of the liver, it is called by some *hepatites parenchymatosa*, and when the gall-bladder which is attached to this organ, is the seat of the inflammation, it has been called *hepatitis cystica.*

The *chronic* species is usually accompanied with a morbid complexion, loss of appetite and flesh, costiveness, indigestion, flatulency, pains in the stomach, a yellow tinge of the skin and eyes, clay-coloured stools, high-coloured urine, depositing a red sediment and ropy mucus; an obtuse pain in the region of the liver, extending to the shoulder, and not unfrequently with a considerable degree of asthma.

These symptoms are, however, often so mild and insignificant as to pass almost unnoticed; as large abscesses have been found in the liver upon dissection, which in the person's life-time had created little or no inconvenience, and which we may presume to have been occasioned by some previous inflammation.

Hepatitis, like other inflammations, may end in resolution, suppuration, gangrene, or scirrhus; but its termination in gangrene is a rare occurrence.

The disease is seldom attended with fatal consequences of an immediate nature, and is often carried off by hæmorrhage from the nose, or hæmorrhoidal vessels, and likewise by sweating, by a diarrhœa, or by an evacuation of urine, depositing a copious sediment. In a few instances, it has been observed to cease on the appearance of erysipelas, in some external part.

When suppuration takes place, as it generally before this forms an adhesion with some neighbouring part, the pus is usually discharged by the different outlets with which this part is connected, as by coughing, vomiting, purging, or by an abscess breaking outwardly; but, in some instances, the pus has been discharged into the cavity of the abdomen, where no such adhesion had been formed.

On dissection, the liver is often found much enlarged, and hard to the touch; its colour is more of a deep purple than what is natural, and its membranes are more or less affected by inflammation. Dissections likewise show that adhesions to the neighbouring parts often take place, and large abscesses, containing a considerable quantity of pus, are often found in its substance.

The treatment of this disease must be distinguished, as it is of the acute, or of the chronic form. In acute hepatitis, where the symptoms run high, and the constitution will admit, we should, in the beginning, bleed freely from the arm; which it will seldom be necessary to repeat, if carried to the proper extent at first: in milder cases, or where there is less power in the system, the local abstraction of blood, by cupping or leeches, may be sufficient. We should next give calomel alone, or combined with opium, and followed up by infusion of senna with neutral salts, jalap, or other cathartic, to evacuate bile, and thoroughly clear out the intestines. When, by these means, the inflammation is materially abated, we should endeavour to promote diaphoresis by suitable medicines, assisted by the warm bath; a blister may be applied; and the antiphlogistic regimen is to be duly enforced. But the discharge of bile, by occasional doses of calomel, must not be neglected; and where the alvine evacuations are deficient in that secretion, it will be proper to push this, or other mercurial preparation, till the mouth is in some measure affected. In India this is the remedy chiefly relied upon, and exhibited often in much larger doses than appear advisable in more temperate climates. Should the disease proceed to suppuration, means must be used to support the strength; a nutritious diet, with a moderate quantity of wine, and decoction of bark, or other tonic medicine: fomentations or poultices will also be proper to promote the discharge externally; but when any fluctuation is perceptible, it is better to make an opening, lest it should burst inwardly. In the chronic form of the disease mercury is the remedy chiefly to be relied upon; but due caution must be observed in its use, especially in scrophulous subjects. It appears more effectual in restoring the healthy action of the liver, when taken internally: but if the mildest forms, though guarded by opium, or rather sedative, cannot so be borne, the ointment may be rubbed in. In the mean-time, calumba, or other tonic, with antacids, and mild aperients, as rhubarb, to regulate the state of the primæ viæ, will be proper. Where the system will not admit the adequate use of mercury, the nitric acid is the most promising substitute. An occasional blister may be required to relieve unusual pain; or where this is very limited and continued, an issue, or seton may answer better. The strength must be supported by a light nutritious diet; and gentle exercise with warm clothing, to maintain the perspiration steadily, is important, in the convalescent state: more especially a sea voyage in persons long resident in India has often appeared the only means of restoring perfect health.

HEPATITIS PARENCHYMATOSA. Inflammation of the substance of the liver.

HEPATITIS PERITONÆALIS. Inflammation in the peritonæum covering the liver.

HEPATOCE'LE. (From ηπαρ, the liver, and κηλη, a tumour.) An hernia, in which a portion of the liver protrudes through the abdominal parietes.

HEPATO'RIUM. The same as *Eupatorium*.

HEPHÆ'STIAS. (From Ηφαιςος, Vulcan, or fire.) A drying plaster of burnt tiles.

HEPI'ALUS. (From ηπιος, gentle.) A mild quotidian fever.

HEPTA'NDRIA. (From επτα, seven, and ανηρ, a man, or husband.) The name of a class in the sexual system of plants, consisting of such hermaphrodite flowers as have seven stamens.

HEPTAPHA'RMACUM. (From επτα, seven, and φαρμακον, medicine.) A medicine composed of seven ingredients, the principal of which were cerusse, litharge, wax, &c.

HEPTAPHY'LLUM. (From επτα, seven, and φυλλον, a leaf: so named because it consists of seven leaves.) See *Tormentilla erecta.*

HEPTAPLE'URUM. (From επτα, seven, and πλευρα, a rib: so named from its having seven ribs upon the leaf.) The herb plantain. See *Plantago major.*

HERA'CLEA. 1. Water horehound.

2. The common wild marjoram received a trivial name from its growing in abundance in Heraclea. See *Origanum vulgare.*

HERA'CLEUM. (From *Heraclea*, the city near which it grows; or from Ἡρακλης, Hercules, being the plant sacred to him.) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Digynia.*

HERACLEUM GUMMIFERUM. This species is supposed by Wildenow to afford the gum ammoniacum. See *Ammoniacum.*

HERACLEUM SPONDYLIUM. *Branca ursina Germanica; Spondylium.* Cow-parsnep. All-heal. *Heracleum—foliolis pinnatifidis, lævibus; floribus uniformibus* of Linnæus. The plant which is directed by the name of *Branca ursina* in foreign pharmacopœias. In Siberia it grows extremely high, and appears to have virtues in the cure of dysentery which the plants of this country do not possess.

HERB-BENNET. See *Geum urbanum.*

HERB-OF-GRACE. See *Gratiola.*

HERB-MASTICH. See *Thymus mastichina.*

Herb-trinity. See *Anemone Hepatica.*

HERBA. An herb. A plant is properly so called which bears its flower and fruit once only, and then with its root wholly perishes. There are two kinds: *annuals*, which perish the same year; and *biennials*, which have their leaves the first year, and their flowers and fruit the second, and then die away.

By the term *herba* Linnæus denominates that portion of every vegetable which arises from the root, and is terminated by the fructification.

HERBA BRITANNICA. See *Rumex hydrolapathum.*

HERBA MILITARIS. See *Achillæa millefolium.*

HERBA SACRA. See *Verbena trifoliata.*

HERBA TRINITATIS. See *Anemone hepatica.*

HERBACEUS. Herbaceous. Plants are so considered which have succulent stems or stalks, and die down to the root every year.

HERBARIUM. A collection of dried or preserved plants; called also *Hortus siccus.*

HERCULES'S ALL-HEAL. See *Laserpitium chironium.*

HERCULES BOVII. Gold and mercury dissolved in a distillation of copperas, nitre, and sea-salt.

HERE'DITARY. (From *hæres*, an heir.) A disease, or predisposition to a disease, which is transferred from parents to their children.

HERMA'PHRODITE. (*Hermaphroditus;* from Ἑρμης, Mercury, and Αφροδιτη, Venus, *i. e.* partaking of both sexes.) 1. The true hermaphrodite of the ancients was, the man with male organs of generation, and the female stature of body, that is, narrow chest and large pelvis; or the woman with female organs of generation, and the male stature of body, that is, broad chest and narrow pelvis. The term is now, however, used to express any *lusus naturæ* wherein the parts of generation appear to be a mixture of both sexes.

2. In botany, an hermaphrodite flower is one which contains both the male and female organs, for the production of the fruit, within the same calyx and petals.

HERME'TIC. (From Ερμης, Mercury.) In the language of the ancient chemists, Hermes was the father of chemistry, and the hermetic seal was the closing the end of a glass vessel while in a state of fusion, according to the usage of chemists.

HERMODACTYL. See *Hermodactylus.*

HERMODA'CTYLUS. (Ἑρμοδακτυλος. Etymologists have always derived this word from Ἑρμης, Mercury, and δακτυλος, a finger. It is, however, probably named from *Hermus*, a river in Asia, upon whose banks it grows, and δακτυλος, a date, which it is like.) *Anima articulorum.* The root of a species of colchicum, not yet ascertained, but supposed to be the *Colchicum illyricum* of Linnæus, of the shape of a heart, flattened on one side, with a furrow on the other, of a white colour, compact and solid, yet easy to cut or powder. This root, which has a viscous, sweetish, farinaceous taste, and no remarkable smell, is imported from Turkey. Its use is totally laid aside in the practice of the present day. Formerly the roots were esteemed as cathartics, which power is wanting in those that reach this country.

HE'RNIA. (From ἑρνος, a branch; from its protruding out of its place.) A rupture. Surgeons understand, by the term *hernia*, a tumour formed by the protrusion of some of the viscera of the abdomen out of that cavity into a kind of sac, composed of the portion of peritoneum, which is pushed before them. However, there are certainly some cases which will not be comprehended in this definition; either because the parts are not protruded at all, or have no hernial sac. The places in which these swellings most frequently make their appearance, are the groin, the naval, the labia pudendi, and the upper and fore-part of the thigh; they do also occur at every point of the anterior part of the abdomen;

and there are several less common instances, in which hernial tumours present themselves at the foramen ovale, in the perinæum, in the vagina, at the ischiatic notch, &c. The parts which, by being thrust forth from the cavity, in which they ought naturally to remain, mostly produce herniæ, are either a portion of the omentum, or a part of the intestinal canal, or both together. But the stomach, the liver, the spleen, uterus, ovaries, bladder, &c. have been known to form the contents of some hernial tumours. From these two circumstances of situations and contents, are derived all the different appellations by which herniæ are distinguished. If a portion of intestine only forms the contents of the tumour, it is called *enterocele;* if a piece of omentum only, *epiplocele;* and if both intestine and omentum contribute to the formation of a tumour, it is called *entero-epiplocele.* When the contents of a hernia are protruded at the abdominal ring, but only pass as low as the groin, or labium pudendi, the case receives the name of *bubonocele,* or *inguinal hernia;* when the parts descend into the scrotum, it is called an *oscheocele,* or *scrotal hernia.* The *crural,* or *femoral hernia,* is the name given to that which takes place below Poupart's ligament. When the bowels protrude at the navel, the case is named an *exomphalos,* or *umbilical hernia;* and *ventral* is the epithet given to the swelling, when it occurs at any other promiscuous part of the front of the abdomen. The *congenital rupture* is a very particular case, in which the protruded viscera are not covered with a common hernial sac of peritoneum, but are lodged in the cavity of the tunica vaginalis, in contact with the testicle; and, as must be obvious, it is not named, like hernia in general, from its situation, or contents, but from the circumstance of its existing from the time of birth.

When the hernial contents lie quietly in the sac, and admit of being readily put back into the abdomen, it is termed a *reducible hernia:* and when they suffer no constriction, yet cannot be put back, owing to adhesions, or their large size in relation to the aperture, through which they have to pass, the hernia is termed *irreducible.* An *incarcerated,* or *strangulated* hernia, signifies one which not only cannot be reduced, but suffers constriction: so that, if a piece of intestine be protruded, the pressure to which it is subjected stops the passage of its contents onward towards the anus, makes the bowel inflame, and brings on a train of most alarming and often fatal consequences.

The general symptoms of a hernia, which is reducible and free from strangulation, are—an indolent tumour at some point of the parietes of the abdomen; most frequently descending out of the abdominal ring, or from just below Poupart's ligament, or else out of the navel; but occasionally from various other situations. The swelling mostly originates suddenly, except in the circumstances above related; and it is subject to a change of size, being smaller when the patient lies down upon his back, and larger when he stands up, or draws in his breath. The tumour frequently diminishes when pressed, and grows large again when the pressure is removed. Its size and tension often increase after a meal, or when the patient is flatulent. Patients with hernia are apt to be troubled with colic, constipation, and vomiting, in consequence of the unnatural situation of the bowels. Very often, however, the functions of the viscera seem to suffer little or no interruption.

If the case be an *enterocele,* and the portion of the intestine be small, the tumour is small in proportion; but though small, yet, if the gut be distended with wind, inflamed, or have any degree of stricture made on it, it will be tense, resist the impression of the finger, and give pain upon being handled. On the contrary, if there be no stricture, and the intestine suffers no degree of inflammation, let the prolapsed piece be of what length it may, and the tumour of whatever size, yet the tension will be little, and no pain will attend the handling it; upon the patient's coughing, it will feel as if it was blown into; and, in general, it will be found very easily returnable. A guggling noise is often made when the bowel is ascending.

If the hernia be an *epiplocele,* or one of the omental kind, the tumour has a more flabby and a more unequal feel; it is in general perfectly indolent, is more compressible, and (if in the scrotum) is more oblong and less round than the swelling occasioned in the same situation by an intestinal hernia; and, if the quantity be large, and the patient an adult, it is, in some measure, distinguishable by its greater weight.

If the case be an *entero-epiplocele,* that is, one consisting of both intestine and omentum, the characteristic marks will be less clear than in either of the simple cases; but the disease may easily be distinguished from every other one, by any body in the habit of making the examination.

HERNIA CEREBRI. *Fungus cerebri.* This name is given to a tumour which every now and then rises from the brain, through an ulcerated opening in the dura mater, and protrudes through a perforation in the cranium, made by the previous application of the trephine.

HERNIA CONGENITA. (So called because it is, as it were, born with the person.) This species of hernia consists in the adhesion of a protruded portion of intestine or omentum to the testicle, after its descent into the scrotum. This adhesion takes place while the testicle is yet in the abdomen. Upon its leaving the abdomen, it draws the adhering intestine, or omentum, along with it into the scrotum, where it forms the hernia congenita.

From the term *congenital,* we might suppose that this hernia always existed at the time of birth. The protrusion, however, seldom occurs till after this period, on the operation of the usual exciting causes of hernia in general. The congenital hernia does not usually happen till some months after birth; in some instances not till a late period. Hey relates a case, in which a hernia congenita was first formed in a young man, aged sixteen, whose right testis had, a little while before the attack of the disease, descended into the scrotum. It seems probable that, in cases of hernia congenita, which actually take place when the testicle descends into the scrotum before birth, the event may commonly be referred, as observed above, to the testicle having contracted an adhesion to a piece of intestine, or of the omentum, in its passage to the ring. Wrisberg found one testicle which had not passed the ring, adhering, by means of a few slender filaments, to the omentum, just above this aperture, in an infant that died a few days after birth.

Excepting the impossibility of feeling the testicle in hernia congenita, as we can in most cases of bubonocele, (which criterion Mr. Samuel Cooper, in his Surgical Dictionary, observes Mr. Pott should have mentioned,) the following account is very excellent. "The appearance of a hernia, in very early infancy, will always make it probable that it is of this kind; but in an adult, there is no reason for supposing his rupture to be of this sort, but his having been afflicted with it from his infancy; there is no external mark, or character, whereby it can be certainly distinguished from the one contained in a common hernial sac; neither would it be of any material use in practice, if there was."

Hernia cruralis. Femoral hernia. The parts composing this kind of hernia are always protruded under Poupart's ligament, and the swelling is situated towards the inner part of the bend of the thigh. The rupture descends on the side of the femoral artery and vein, between these vessels and the os pubis. Females are particularly subject to this kind of rupture in consequence of the great breadth of their pelvis, while in them the inguinal hernia is rare. It has been computed, that nineteen out of twenty married women, afflicted with hernia, have this kind; but that not one out of a hundred unmarried females, or out of the same number of men, have this form of the disease. The situation of the tumour makes it liable to be mistaken for an enlarged inguinal gland; and many fatal events are recorded to have happened from the surgeon's ignorance of the existence of the disease. A gland can only become enlarged by the gradual effects of inflammation; the swelling of a crural hernia comes on in a momentary and sudden manner; and, when strangulated, occasions the train of symptoms described in the account of the hernia incarcerata, which symptoms an enlarged gland could never occasion. Such circumstances seem to be sufficiently discriminative: though the feel of the two kinds of swelling is often not in itself enough to make the surgeon decided in his opinion. A femoral hernia may be mistaken for a bubonocele, when the expanded part of the swelling lies over Poupart's ligament. As the taxis and operation for the first case ought to be done differently from those for the latter, the error may lead to very bad consequences. The femoral hernia, however, may always be discriminated, by the neck of the tumour having Poupart's ligament above it. In the bubonocele, the angle of the pubes is behind and below this part of the sac; but in the femoral hernia, it is on the same horizontal level, a little on the inside of it.

Until very lately, the stricture, in cases of femoral hernia, was always supposed to be produced by the lower border of the external oblique muscle, or, as it is termed, Poupart's ligament. A total change of surgical opinion on this subject has, however, latterly taken place, in consequence of the accurate observations first made in 1768, by Gimbernat, surgeon to the king of Spain. In the crural hernia, (says he,) the aperture through which the parts issue is not formed by two bands, as in the inguinal hernia,) but it is a foramen, almost round, proceeding from the internal margin of the crural arch, (Poupart's ligament,) near its insertion into the branch of the os pubis, between the bone and the iliac vein, so that, in this hernia, the branch of the os pubis is situated more internally than the intestine, and a little behind; the vein externally, and behind; and the internal border of the arch before. Now it is this border which always forms the strangulation.

Hernia flatulenta. A swelling of the side, caused by air that has escaped through the pleura; an obsolete term.

Hernia gutturis. Bronchocele, or tumour of the bronchial gland.

Hernia humoralis. See *Orchitis*.

Hernia incarcerata. Incarcerated hernia. Strangulated hernia, or a hernia with stricture. The symptoms are a swelling in the groin, &c. resisting the impression of the fingers. If the hernia be of the intestinal kind, it is generally painful to the touch, and the pain is increased by coughing, sneezing, or standing upright. These are the very first symptoms, and, if they are not relieved, are soon followed by others; viz. a sickness at the stomach, a frequent retching, or inclination to vomit, a stoppage of all discharge per anum, attended with frequent hard pulse, and some degree of fever. These are the first symptoms; and if they are not appeased by the return of the intestine, that is, if the attempts made for this purpose do not succeed, the sickness becomes more troublesome, the vomiting more frequent, the pain more intense, the tension of the belly greater, the fever higher, and a general restlessness comes on, which is very terrible to bear. When this is the state of the patient, no time is to be lost; a very little delay is now of the utmost consequence; and if the one single remedy which the disease is now capable of, be not administered immediately, it will generally baffle every other attempt. This remedy is the operation whereby the parts engaged in the stricture may be set free. If this be not now performed, the vomiting is soon exchanged for a convulsive hiccup, and a frequent gulping up of bilious matter: the tension of the belly, the restlessness and fever, having been considerably increased for a few hours, the patient suddenly becomes perfectly easy, the belly subsides, the pulse, from having been hard, full, and frequent, becomes low, languid, and generally interrupted; and the skin, especially that of the limbs, cold and moist; the eyes have now a languor and glassiness, a lack lustre not easy to be described: the tumour of the part disappears, and the skin covering it sometimes changes its natural colour for a livid hue; but whether it keeps or loses its colour, it has an emphysematous feel, a crepitus to the touch, which will easily be conceived by all who have attended to it, but is not easy to convey an idea of by words. This crepitus is the too sure indicator of gangrenous mischief within. In this state, the gut either goes up spontaneously, or is returned with the smallest degree of pressure; a discharge is made by stool, and the patient is generally much pleased at the ease he finds; but this pleasure is of short duration, for the hiccup and the cold sweats, continuing and increasing, with the addition of spasmodic rigours and subtultus tendinum, the tragedy soon finishes.

Hernia inguinalis. *Bubonocele.* Inguinal hernia. *The hernia inguinalis* is so called because it appears in both sexes at the groin. It is one of the divisions of hernia, and includes all those herniæ in which the parts displaced pass out of the abdomen through the ring, that is, the arch formed by the aponeurosis of the musculus obliquus externus in the groin, for the passage of the spermatic vessels in men, and the round ligament in women. The parts displaced that form the hernia, the part into which they fall, the manner of the hernia being produced, and the time it has continued, occasion great differences in this disorder. There are three different parts that may produce a hernia in the groin, viz. one or more of the intestines, the epiploon, and the bladder. That which is formed by one or more of the intestines, was called, by the ancients, *enterocele.* The intestine which most frequently produces the hernia, is the *ilium:* because, being placed in the iliac region, it is nearer the groin than the rest: but notwithstanding the situation of the other intestines, which seems not to allow of their coming near the groin, we often find the jejunum, and frequently also a portion of the colon and cæcum, included in the hernia. It must be remembered, that the mesentery and mesocolon are membranous substances, capable of extension, which, by little and little, are sometimes so far stretched by the weight of the intestines, as to escape with the ilium, in this species of hernia. The hernia made by the epiploon is called *epiplocele;* as that caused by the epiploon and any of the intestines together is called *entero epiplocele.* The hernia of the bladder is called *crytocele.* Hernia of the bladder is uncommon, and has seldom been known to happen but in conjunction with some of the other viscera. When the parts, having passed through the abdominal rings, descend no lower than the groin, it is called an incomplete hernia; when they fall into the scrotum in men, or into the *labia pudendi* in women, it is then termed complete.

The marks of discrimination between some other diseases and inguinal hernia are these:—

The disorders in which a mistake may possibly be made, are the circocele, bubo, hydrocele, and hernia humoralis, or inflamed testicle.

For an account of the manner of distinguishing circocele from a bubonocele, see *Circocele.*

The circumscribed incompressible hardness, the situation of the tumour, and its being free from all connection with the spermatic process, will sufficiently point out its being a bubo, at least while it is in a recent state; and when it is in any degree suppurated, he must have a very small share of the *tactus eruditus* who cannot feel the difference between matter, and either a piece of intestine or omentum.

The perfect equality of the whole tumour, the freedom and smallness of the spermatic process above it, the power of feeling the spermatic vessels, and the vas deferens in that process; its being void of pain upon being handled, the fluctuation of the water, the gradual formation of the swelling, its having begun below and proceeded upwards, its not being affected by any posture or action of the patient, nor increased by his coughing or sneezing, together with the absolute impossibility of feeling the testicle at the bottom of the scrotum, will always, to an intelligent person, prove the disease to be hydrocele.

Pott, however, allows that there are some exceptions in which the testicle cannot be felt at the bottom of the scrotum, in cases of hernia. In recent bubonoceles, while the hernial sac is thin, has not been long, or very much distended, and the scrotum still preserves a regularity of figure, the testicle may almost always be easily felt at the inferior and posterior part of the tumour. But in old ruptures, which have been long down, in which the quantity of contents is large, the sac considerably thickened, and the scrotum of an irregular figure, the testicle frequently cannot be felt; neither is it in general easily felt in the *congenital hernia,* for obvious reasons.

In the *hernia humoralis,* the pain in the testicle, its enlargement, the hardened state of the epididymis, and the exemption of the spermatic cord from all unnatural fulness, are such marks as cannot easily be mistaken; not to mention the generally preceding gonorrhœa. But if any doubt still remains of the true nature of the disease, the progress of it from above downwards, its different state and size in different postures, particularly lying and standing, together with its descent and ascent, will, if duly attended to, put it out of all doubt that the tumour is a *true hernia.*

When an inguinal hernia does not descend through the abdominal ring, but only into the canal for the spermatic cord, it is covered by the aponeurosis of the external oblique muscle, and the swelling is small and undefined.

Now and then, the testicle does not descend into the scrotum till a late period. The first appearance of this body at the ring, in order to get into its natural situation, might be mistaken for that of a hernia, were the surgeon not to pay attention to the absence of the testicle from the scrotum, and the peculiar sensation occasioned by pressing the swelling.

HERNIA INTESTINALIS. A rupture caused by the protrusion of a portion of the intestine. See *Hernia inguinalis.*

HERNIA ISCHIATICA. A rupture at the ischiatic notch. This is very rare. A case, however, which was strangulated, and undiscovered till after death, is related in Sir A. Cooper's second part of his work on hernia. The disease happened in a young man aged 27. On opening the abdomen, the ilium was found to have descended on the right side of the rectum into the pelvis; and a fold of it was protruded into a small sac, which passed out of the pelvis at the ischiatic notch. The intestine was adherent to the sac at two points: the strangulated part, and about three inches on each side were very black. The intestines towards the stomach, were very much distended with air, and here and there had a livid spot on them. A dark spot was even found on the stomach itself, just above the pylorus. The colon was exceedingly contracted, as far as its sigmoid flexture. A small orifice was found in the side of the pelvis, in front of, but a little above the sciatic nerve, and on the fore part of the pyriformis muscle. The sac lay under the glutæus maximus muscle, and its orifice was before the internal iliac artery, below the obturator artery, but above the vein.

HERNIA LACHRYMALIS. When the tears pass through the puncta lachrymalia, but stagnate in the sacculus lachrymalis, the tumour is styled *hernia lachrymalis* with little propriety or precision. It is with equal impropriety called, by Anel, *a dropsy of the lachrymal sac.* If the inner angle of the eye is pressed, and an aqueous humour flows out, the disease is the *fistula lachrymalis.*

HERNIA MESENTERICA. Mesenteric hernia. If one of the layers of the mesentery be torn by a blow, while the other remains in its natural state, the intestines may insinuate themselves into the aperture and form a kind of hernia. The same consequences may result from a natural deficiency in one of these layers. Sir A. Cooper relates a case, in which all the small intestines, except the duodenum, were thus circumstanced. The symptoms during life were unknown.

HERNIA MESOCOLICA. Mesocolic hernia. So named by Sir A. Cooper, when the bowels glide between the layers of the mesocolon. Every surgeon should be aware that the intestines may be strangulated from the following causes: 1. Apertures in the omentum, mesentery, or mesocolon, through which the intestine protrudes. 2. Adhesions, leaving an aperture, in which a piece of intestine becomes confined. 3. Membranous bands at the mouths of hernial sacs, which becoming elongated by the frequent protrusion and return of the viscera, surround the intestine, so as to strangulate them within the abdomen when returned from the sac.

HERNIA OMENTALIS. *Epiplocele.* A rupture of the omentum; or a protrusion of the omentum through apertures in the integuments of the belly. Sometimes according to Sharpe, so large a quantity of the omentum hath fallen into the scrotum, that its weight, drawing the stomach and bowels downwards, hath excited vomiting, inflammation, and symptoms similar to those of the incarcerated hernia.

HERNIA PERINEALIS. Perineal hernia. In men, the parts protrude between the bladder and rectum; in women, between the rectum and vagina. The hernia does not project so as to form an external tumour; and in men, its existence can only be distinguished by examining in the rectum. In women, it may be detected both from this part and the vagina.

HERNIA PHRENICA. Phrenic hernia. The abdominal viscera are occasionally protruded through the diaphragm, either through some of the natural apertures in this muscle, or deficiencies, or wounds and lacerations in it. The second kind of case is the most frequent. Morgagni furnishes an instance of the first. Two cases related by Dr. Macauley, and two others published by Sir A. Cooper, are instances of the second sort. And another case has been lately recorded by the latter gentleman, affording an example of the third kind. Hildanus, Parè, Petit, Schenck, &c. also mention cases of phrenic hernia.

HERNIA PUDENDALIS. Pudendal hernia. This is the name assigned by Sir A. Cooper, to that which descends between the vagina and ramus ischii, and forms an oblong tumour in the labium, traceable within the pelvis, as far as the os uteri. Sir A. C. thinks this case has sometimes been mistaken for a hernia of the foramen ovale.

HERNIA SCROTALIS. *Hernia Oschealis. Oscheocele.* Paracelsus calls it *Crepatura.* When the omentum, the intestine, or both, descend into the scrotum, it has these appellations; when the omentum only, it is called *epiploscheocele.* It is styled a perfect rupture in contradistinction to a bubonocele, which is the same disorder; but the descent is not so great. The hernia scrotalis is distinguished into the true and false; in the former, the omentum or intestine, or both, fall into the scrotum; in the latter, an inflammation, or a fluid, causes a tumour in this part, as in hernia humoralis, or hydrocele. Sometimes cebaceous matter is collected in the scrotum; and this hernia is called *steatocele.*

HERNIA THYROIDEALIS. *Hernia foraminis ovalis.* Thyroideal hernia. In the anterior and upper part of the obturator ligament there is an opening, through which the obturator artery, vein, and nerve proceed, and through which occasionally a piece of omentum or intestine is protruded, covered with a part of the peritonæum, which constitutes the hernial sac.

HERNIA UMBILICALIS. *Epiploomphalion; Omphalocele; Exomphalos; Omphalos;* and, when owing to flatulency, *Pneumatomphalos.* The exomphalos, or umbilical rupture, is so called from its situation, and has, like other herniæ, for its general contents, a portion of intestine, or omentum, or both. In old umbilical ruptures, the quantity of omentum is sometimes very great. Mr. Ranby says, that he found two ells and a half of intestine in one of these, with about a third part of the stomach, all adhering together. Gay and Nourse found the liver in the sac of an umbilical hernia; and Bohnius says that he did also. But whatever are the contents, they are originally contained in the sac, formed by the protrusion of the peritoneum.

In recent and small ruptures, this sac is very visible; but in old and large ones, it is broken through at the knot of the navel, by the pressure and weight of the contents, and is not always to be distinguished; which is the reason why it has by some been doubted whether this kind of rupture has a hernial sac or not.

Infants are very subject to this disease, in a small degree, from the separation of the funiculus; but in general they either get rid of it as they gather strength, or are easily cured by wearing a proper bandage. It is of still more consequence to get this disorder cured in females, than in males; that its return, when they are become adult and pregnant, may be prevented as much as possible; for at this time it often happens, from the too great distention of the belly, or from unguarded motion, when the parts are upon the stretch.

Dr. Hamilton has met with about two cases annually for the space of seventeen years, of umbilical hernia, which strictly deserve the name of *congenital* umbilical hernia. The funis ends in a sort of bag, containing some of the viscera, which pass out of the abdomen through an aperture in the situation of the navel. The swelling is not covered with skin, so that the contents of the hernia can be seen through the then distended covering of the cord. The disease is owing to a preternatural deficiency in the abdominal muscles, and the hope of cure must be regulated by the size of the malformation and quantity of viscera protruded.

HERNIA UTERI. *Hysterocele.* Instances have occurred of the uterus being thrust through the rings of the muscles; but this is scarcely to be discovered, unless in a pregnant state, when the strugglings of a child would discover the nature of the disease. In that state, however, it could scarcely ever occur. It is the *cerexis* of Hippocrates.

HERNIA VAGINALIS. *Elytrocele.* Vaginal hernia. A tumour occurs within the os externum of the vagina. It is elastic, but not painful. When compressed, it readily recedes, but is reproduced by coughing, or even without this, when the pressure is removed. The inconveniences produced are an inability to undergo much exercise or exertion; for every effort of this sort brings on a sense of bearing down. The vaginal hernia protrudes in the space left between the uterus and rectum. This space is bounded below by the peritoneum, which membrane is forced downwards, towards the perinæum; but being unable to protrude further in that direction, is pushed towards the back part of the vagina. These cases probably are always intestinal. Some herniæ protrude at the anterior part of the vagina.

HERNIA VARICOSA. See *Circocele.*

HERNIA VENTOSA. See *Pneumatocele.*

HERNIA VENTRALIS. *Hypogastrocele.* The ventral hernia may appear at almost any point of the anterior part of the belly, but is most frequently found between the recti muscles. The portion of intestine, &c. &c. is always contained in a sac made by the protrusion of the peritonæum. Sir A. Cooper imputes its causes to the dilatation of the natural foramina, for the transmission of vessels, to congenital deficiencies, lacerations, and wounds of the abdominal muscles, or their tendons. In small ventral herniæ, a second fascia is found beneath the superficial one; but in large ones the latter is the only one covering the sac.

HERNIA VENTRICULI. *Gastrocele.* A ventral rupture caused by the stomach protruding through some part of the abdominal parietes. It rarely occurs, but it does it generally at or near the navel.

HERNIA VESICALIS. *Hernia cystica; Cystocele.* The urinary bladder is liable to be thrust forth, from its proper situation, either through the opening in the oblique muscle, like the inguinal hernia, or under Poupart's ligament, in the same manner as the femoral.

This is not a very frequent species of hernia, but does happen, and has as plain and determined a character as any other.

HERNIA'RIA. (From *hernia*, a rupture: so called from its supposed efficacy in curing ruptures.) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Digynia.* Rupture-wort.

HERNIARIA GLABRA. The systematic name of the rupture-wort. *Herniaria.* This plant, though formerly esteemed as efficacious in the cure of hernias, appears to be destitute, not only of such virtues, but of any other. It has no smell nor taste.

HERNIO'TOMY. (*Herniotomia;* from *hernia*, and τεμνω, to cut.) The operation to remove the strangulated part in cases of incarcerated herniæ.

HE'RPES. (From ἑρπω, to creep; because it creeps and spreads about the skin.) Tetter. A genus of disease in the class *Locales*, and order *Dialyses*, of Cullen, distinguished by an assemblage of numerous little creeping ulcers, in clusters, itching very much, and difficult to heal, but terminating in furfuraceous scales.

Bell, in his Treatise on Ulcers, arranges the herpes among the cutaneous ulcers, and says, that all the varieties of importance may be comprehended in the four following species:

1. *Herpes farinosus*, or what may be termed the *dry tetter*, is the most simple of all the species. It appears indiscriminately in different parts of the body, but most commonly on the face, neck, arms, and wrists, in pretty broad spots and small pimples. These are generally very itchy, though not otherwise troublesome; and, after continuing a certain time, they at last fall off in the form of a white powder, similar to fine bran, leaving the skin below perfectly sound; and again returning in the form of a red efflorescence, they fall off, and are renewed as before.

2. *Herpes pustulosus.* This species appears in the form of pustules, which originally are separate and distinct, but which afterwards run together in clusters. At first, they seem to contain nothing but a thin watery serum, which afterwards turns yellow, and, exuding over the whole surface of the part affected, it at last dries into a thick crust, or scab; when this falls off, the skin below frequently appears entire, with only a slight degree of redness on its surface; but on some occasions, when the matter has probably been more acrid, upon the scab falling off, the skin is found slightly excoriated. Eruptions of this kind appear most frequently on the face, behind the ears, and on other parts of the head; and they occur most commonly in children.

3. *Herpes miliaris.* The miliary tetter. This breaks out indiscriminately over the whole body; but more frequently about the loins, breast, perinæum, scrotum, and inguina, than in other parts. It generally appears in clusters, though sometimes in distinct rings, or circles, of very minute pimples, the resemblance of which to the millet-seed has given rise to the denomination of the species. The pimples are at first, though small, perfectly separate, and contain nothing but a clear lymph, which, in the course of this disease, is excreted upon the surface, and there forms into small distinct scales; these, at last, fall off, and leave a considerable degree of inflammation below, and still continues to exude fresh matter, which likewise forms into cakes, and so falls off as before. The itching, in this species of complaint, is always very troublesome; and the matter discharged from the pimples is so tough and viscid, that every thing applied to the part adheres, so as to occasion much trouble and uneasiness on its being removed.

4. *Herpes exedens*, the eating and corroding tetter (so called from its destroying or corroding the parts which it attacks,) appears commonly, at first, in the form of several small painful ulcerations, all collected into larger spots, of different sizes and of various figures, with always more or less of an erysipelatous inflammation. These ulcers discharge large quantities of a thin, sharp, serous matter, which sometimes forms into small crusts, that in a short time fall off; but most frequently the discharge is so thin and acrid as to spread along the neighbouring parts, where it soon produces the same kind of sores. Though these ulcers do not, in general, proceed farther than the cutis vera, yet sometimes the discharge is so very penetrating and corrosive as to destroy the skin, cellular substance, and, on some occasions, even the muscles themselves. It is this species that should be termed the *depascent*, or *phagedenic* ulcer, from the great destruction of parts which it frequently occasions. See *Phagedæna.*

HERPES AMBULATIVA. A species of erysipelas which moves from one part to another.

HERPES DEPASCENS. The same as herpes exedens. See *Herpes.*

HERPES ESTHIOMENOS. Herpes destroying the skin by ulceration.

HERPES FARINOSUS. See *Herpes.*

HERPES FERUS. An erysipelas.

HERPES INDICA. A fiery, itchy herpes, peculiar to India.

HERPES MILIARIS. See *Herpes.*

HERPES PERISCELIS. The shingles. See *Erysipelas phlyctænodes.*

HERPES PUSTULOSUS. See *Herpes.*

HERPES SERPIGO. The ring-worm.

HERPES SICCUS. The dry, mealy tetter.

HERPES ZOSTER. Shingles encircling the body. See *Eryspelas.*

HERPETIC. Relating to herpes.

HE'RPETON. (From ἑρπω, to creep.) A creeping pustule, or ulcer.

HESPERIDEÆ. (From *Hesperides*, whose orchards, according to the poets, produced golden apples.) Golden or precious fruit. The name of an order of plants in Linnæus' Fragments of a Natural Method, consisting of plants which have rigid ever-green leaves; odorous and polyandrous flowers; as the myrtle, clove, &c.

HEWSON, WILLIAM, was born at Hexham, in 1739. After serving an apprenticeship to his father, he came to London at the age of twenty, and resided with Mr. John Hunter, attending also the lectures of Dr. Hunter. His assiduity and skill were so conspicuous, that he was appointed to superintend the dissecting room, when the former went abroad with the army in 1760. He then studied a year at Edinburgh, and in 1762 he became associated with Dr. Hunter in delivering the anatomical lectures, and he was afterwards allowed an apartment in Windmill-street. Here he pursued his anatomical investigations, and his experimental enquiries into the properties of the blood, of which he published an account in 1771. He also communicated to the Royal Society several papers concerning the lymphatic system in birds and fishes, for which he received the Copleyan medal, and was soon after elected a fellow of that body. He began a course of lectures alone in 1772, having quitted Dr. Hunter two years before, and soon became very popular. In 1774, he published his work on the Lymphatic system. But not long after, his life was terminated by a fever, occasioned by a wound received in dissecting a morbid body, in the thirty-fifth year of his age.

HEXAGY'NIA. (From ἑξ, six, and γονη, a woman, or wife.) The name of an order of plants in the sexual system, which, besides the classic character, have six females or pistils.

HEXA'NDRIA. (From ἑξ, six, and ανηρ, a man, or husband.) The name of a class of plants in the sexual system, consisting of plants with hermaphrodite flowers that are furnished with six stamens of an equal length.

Hexapha'rmacum. (From ἑξ, six, and φαρμακον, a medicine.) Any medicine in the composition of which are six ingredients.

Hibe'rnicus lapis. See *Lapis hibernicus.*

HIBI'SCUS. (From ιβις, a stork, who is said to chew it, and inject it as a clyster.) The name of a genus of plants in the Linnæan system. Class, *Monadelphia* ; Order, *Polyandria.*

Hibiscus abelmoschus. The systematic name of the plant, the seeds of which are called musk-seed ; *Abelmoschus ; Granum moschi ; Moschus Arabum ; Ægyptia moschata; Bamia moschata ; Alcea ; Alcea Indica ; Alcea Ægyptiaca villosa ; Abrette ; Abelmosch ; Abelmusk.* The plant is indigenous in Egypt, and in many parts of both the Indies. These seeds have the flavour of musk. The best comes from Martinica. By the Arabians, they are esteemed cordial, and are mixed with their coffee, to which they impart their fragrance. In this country, they are used by the perfumers.

HICCUP. *Singultus.* A spasmodic affection of the diaphragm, generally arising from irritation produced by acidity in the stomach, error of diet, &c.

HIDRO'A. (From ιδρως, sweat.) A pustular disease, produced by sweating in hot weather.

HIDRO'CRISIS. (From ιδρως, sweat, and κρινω, to judge.) A judgment formed from the sweat of the patient.

HIDRO'NOSOS. (From ιδρως, sweat, and νοσος, a disease.) The sweating sickness.

HIDROPY'RETUS. (From ιδρως, sweat, and πυρετος, a fever.) Sweating fever.

HIDRO'TICA. (From ιδρως, sweat.) Medicines which cause perspiration.

HIDROTOPOIE'TICA. (From ιδρως, sweat, and ποιεω, to make.) Sudorifics.

HI'ERA. (From ιερος, holy : and from ιεραξ, a hawk.) Holy. Also applied to some plants which hawks are said to be fond of.

Hiera picra. (From ιερος, holy, and πικρος, bitter. Holy bitter.) *Pulvis aloeticus*, formerly called *hiera logadii*, made in the form of an electuary with honey. It is now kept in the form of dry powder, prepared by mixing Socotorine aloes, one pound, with three ounces of white canella.

Hierabo'tane. (From ιερος, holy, and βοτανη, an herb : so called from its supposed virtues. See *Verbena trifoliata.*

Hieraca'ntha. (From ιεραξ, a hawk, and ανθος, a flower : so named because it seizes passengers as a hawk does its prey. A sort of thistle.

HIERA'CIUM. (From ιεραξ, a hawk : so called because hawks feed upon it, or because it was said that hawks applied the juice of it to cleanse their eyes.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia* ; Order, *Polygamia æqualis.* Hawk-weed.

Hieracium pilosella. The systematic name of the mouse-ear, *Auricula muris ; Pilosella ; Myosotis ; Hieraculum.* This common plant, contains a bitter lactescent juice, which has a slight degree of astringency. The roots are more powerful than the leaves. They are very seldom used in this country.

Hiera'culum. See *Hieracium.*

HIERA'NOSOS. (From ιερος, holy, and νοσος, a disease : so called because it was supposed to be that disorder which our Saviour cured in those who were said to be possessed of devils.) The epilepsy.

Hiera'ticum. (From ιερος, holy.) A poultice for the stomach, so named from its supposed divine virtues.

Highgate resin. See *Fossil copal.*

HIGHMORE, Nathaniel, was born at Fordingbridge, in Hampshire, in 1613. After graduating at Oxford, he settled at Sherborne, where he obtained considerable reputation in practice, and died in 1684. He pursued the study of anatomy with zeal, though with limited opportunities of dissection ; and his name has been attached to a part, though not originally discovered by him, namely, the Antrum Maxillare, which had been before mentioned by Casserius. His principal work is "Corporis humani Disquisitio anatomica," printed at the Hague in 1651, with figures, chiefly from Vesalius. He also published two dissertations on Hysteria and Hypochondriasis ; and a history of Generation.

Highmore's antrum. See *Antrum of Highmore.*

Higue'ro. The calabash tree, the fruit of which is said to be febrifuge.

HILDA'NUS. See *Fabricius, William.*

HILUM. The scar, or point by which the seed is attached to its seed vessel or receptacle, and through which alone life and nourishment are conveyed for the perfecting of its internal parts. Consequently all those parts must be intimately connected with the inner surface of this scar, and they are all found to meet there, and to divide or divaricate from that point, more or less immediately. In describing the form or various external portions of any seed, the *hilum* is always to be considered as the base. When the seed is quite ripe, the communication through this channel is interrupted, it separates from the parent plant without injury, a scar being formed on each. Yet the hilum is so far capable of resuming its former nature, that the moisture of the earth is imbibed through it, previous to germination.—*Smith.*

Himanto'sis. (From ιμας, a thong of leather.) A relaxation of the uvula, when it hangs down like a thong.

Hi'mas. A relaxation of the uvula.

Hin. *Hindisch. Hing.* Assafœtida.

HIP. The ripe fruit of the dog-rose. They are chiefly used as a sweet-meat, or in a preserved state. See *Confectio rosæ caninæ.*

HIPPOCAMPUS. (Ιπποκαμπος, the name of a sea insect which has a head like that of the horse, and tail like the καμπη, or *eruca.*) 1. The sea horse.

2. Some parts are so called from their supposed resemblance. See *Cerebrum.*

HIPPOCA'STANUM. (From ιππος, a horse, and καϛανον, a chesnut ; so called from its size.) See *Æsculus hippocastanum.*

HIPPOCRATES, usually called the father of physic, was born in the island of Cos, about 460 years before Christ. He is reckoned the 18th lineal descendant from Æsculapius, the profession of medicine having been hereditarily followed in that family, under whose direction the Coan school attained its high degree of eminence, and by the mother's side he is said to have descended from Hercules. Born with these advantages, and stimulatd by the fame of his ancestors, he devoted himself zealously to the cultivation of the healing art. Not content with the empirical practice, which was derived from his predecessors, he studied under Herodicus, who had invented the gymnastic medicine, as well as some other philosophers. But he appears to have judged carefully for himself, and to have adopted only those principles, which seemed founded in sound reason. He was thus enabled to throw light on the deductions of experience, and clear away the false theories with which medicine had been loaded by those who had no practical knowledge of diseases, and bring it into the true path of observation, under the guidance of reason. Hence the physicians of the rational or dogmatic sect always acknowledged him as their leader. The events of his life are involved in much obscurity and fable. But he appears to have travelled much, residing at different places for some time, and practising his profession there. He died at Larissa, in Thessaly, at a very advanced age, which is variously stated from 85 to 109 years. He left two sons, Thessalus and Draco, who followed the same profession, and a daughter, married to his favourite pupil Polybus, who arranged and published his works; and he formed many other disciples. He acquired a high reputation among his countrymen, which has descended to modern times; and his opinions have been respected as oracles, not only in the schools of medicine, but even in the courts of law. He has shared with Plato the title of divine; statues and temples have been erected to his memory, and his altars covered with incense, like those of Æsculapius himself. Indeed, the qualifications and duties required in a physician, were never more fully exemplified than in his conduct, and more eloquently described than by his pen. He is said to have admitted no one to his instructions without the solemnity of an oath, in which the chief obligations are, the most religious attention to the advantages of the sick, the strictest chastity, and inviolable secrecy concerning matters which ought not to be divulged. Besides these characteristics, he displayed great simplicity, candour, and benevolence, with unwearied zeal in investigating the progress and nature of disease, and in administering to their cure. The books attributed to him amount to 72, of which, however, many are considered spurious and others have been much corrupted. The most esteemed, and generally admitted genuine, are the essay "On Air, Water, and Situation," the first and third books of "Epidemics," that on "Prognostics," the "Aphorisms," the treatise "On the Diet in acute Diseases," and that "On Wounds of the Head." He wrote in the Ionic dialect, in a pure but remarkably concise style. He was necessarily deficient in the knowledge of anatomy, as the dissection of human bodies was not then allowed; whence his Physiology also is, in many respects, erroneous: but he, in a great measure, compensated this by unceasing observation of diseases, whereby he attained so much skill in pathology and therapeutics, that he has been regarded as the founder of medical science: and his opinions still influence the healing art in a considerable degree. He diligently investigated the several causes of diseases, but especially their symptoms, which enabled him readily to distinguish them from each other: and very few of those noticed by him are now unknown, mostly retaining even the same names. But he is more remarkably distinguished by his Prognostics, which have been comparatively little improved since, founded upon various appearances in the state of the patient, but especially upon the excretions. His attention seems to have been directed chiefly to these in consequence of a particular theory. He supposed that there are four humours in the body, blood, phlegm, yellow and black bile, having different degrees of heat or coldness, moisture or dryness, and that to certain changes in the quantity or quality of these all diseases might be referred; and farther, that in acute disorders a concoction of the morbid humours took place, followed by a critical discharge, which he believed to happen especially on certain days. But he seems to have paid little, if any, attention, to the state of the pulse. He advanced another opinion, which has since very generally prevailed, that there is a principle, or power in the system, which he called Nature, tending to the preservation of health, and the removal of disease. He, therefore, advised practitioners carefully to observe and promote the efforts of nature, at the same time correcting morbid states by their opposites, and endeavouring to bring back the fluids into their proper channels. The chief part of his treatment at first was a great restriction of the diet; in very acute diseases merely allowing the mouth to be moistened occasionally for three or four days, and only a more plentiful dilution during a fortnight, provided the strength would bear it: afterwards a more substantial diet was directed, but hardly any medicines, except gentle emetics, and laxatives, or glysters. Where these means failed, very active purgatives were employed, as hellebore, elaterium, &c., or sometimes the sudorific regimen, or garlic and other diuretics. He seems cautious in the use of narcotics, but occasionally had recourse to some of the preparations of lead, copper, silver, and iron. He bled freely in cases of extreme pain or inflammation, sometimes opening two veins at once, so as to produce fainting; and also took blood often by cupping, but preferably from a remote part, with a view of producing a revulsion. Where medicines fail, he recommends the knife, or even fire, as a last resource, and he advises trepanning, in cases of violent headache. But he wishes the more difficult operations of surgery to be performed only by particular persons, who might thereby acquire more expertness.

HIPPOCRATIC. Relating to Hippocrates. See *Facies hippocratica.*

Hippola'pathum. (From ἱππος, a horse, and λαπαθον, the lapathum.) A species of lapathum; so named from its size. See *Rumex patientia.*

Hippoma'rathrum. (From ἱππος, a horse, and μαραθρον, fennel: so named from its size.) See *Peucedanum silaus.*

Hipposeli'num. (From ἱππος, a horse, and σελινον, purslane; so named because it resembles a large kind of purslane.) See *Smyrnium olusatrum.*

HIPPU'RIS. (From ἱππος, a horse, and ουρα, a tail.) 1. Some herbs are thus named because they resemble a horse's tail.

2. The name of a genus of plants in the Linnæan system. Class, *Monandria;* Order, *Monogynia.* Mare's tail.

Hippurus vulgaris. The systematic name of the horse's or mare's tail. *Equisetum; Cauda equina.* It possesses astringent qualities, and is frequently used by the common people as tea in diarrhœas and hæmorrhages. The same virtues are also attributed to the *Equisetum arvense, fluviatile, limosum,* and other species, which are directed indiscriminately by the term *Equisetum.*

HIPPUS. (From ἱππος, a horse; because the eyes of those who labour under this affection are continually twinkling and trembling, as is usual with those who ride on horseback.) A repeated dilatation and alternate constriction of the pupil, arising from spasm, or convulsion of the iris.

Hir. (From χειρ, the hand.) The palm of the hand.

Hira. (From *hir*, the palm of the hand; because it is usually found empty.) The intestinum jejunum.

HIRCUS. *Tragus.* The goat.

Hircus bezoarticus. (*Quasi hirtus*; from his shaggy hair.) The goat which affords the oriental bezoar.

Hi′rquus. (From ερκος, a hedge; because it is hedged in by the eye-lash.) The angle of the eye.

HIRSUTIES. A trivial name in Good's Nosology for a species of disease in which hair grows in extraneous parts, or superfluously in parts where it naturally grows. *Trichosis hirsuties.*

HIRSUTUS. Hairy: applied to leaves, petals, seeds, &c. of plants; as the petals of the *Menyanthes trifoliata* and *Asclepias crispa*: the seeds of the *Scandix trichosperma.*

HI′RTUS. (A contraction of *hirsutus.*) Hairy: applied to stems of plants, as that of the *Cirastium alpinum.*

HIRU′DO. (*Quasi haurudo;* from *haurio*, to draw out: so named from its greediness to suck blood.) See *Leech.*

Hirudo medicinalis. See *Leech.*

HIRUNDINA′RIA. (From *hirundo*, the swallow: so called from the resemblance of its pods to a swallow.) Swallow-wort, or asclepias. See *Lysimachia nummularia*, and *Asclepias vincetoxicum.*

Hiru′ndo. (*Ab hærendo;* from its sticking its nest to the eaves of houses.)

1. The swallow.

2. The cavity in the bend of the arm.

Hispi′dula. (From *hispidus*, rough: so named from the rough, woolly surface of its stalks.) See *Gnaphalium.*

HISPIDUS. Bristly: applied to stems, seeds, &c. of plants. The *Borago officinalis* is a good example of the *Caulus hispidus*: the seeds of the *Daucus carota*, and *Galium boreale.*

HODGES, Nathaniel, son of the Dean of Hereford, was born at Kensington, and graduated at Oxford in 1659. He then settled in London, and continued there during the plague, when most other physicians deserted their post. He was twice taken ill, but by timely remedies recovered. He afterwards published an authentic account of the disease, which appears to have destroyed 68,596 persons in the year 1665. It is to be regretted, that a person who had performed such an important and dangerous service to his fellow-citizens, should have died in prison, confined for debt, in 1684.

HOFFMAN, Frederic, was born at Halle, in Saxony, 1660. Having lost his parents from an epidemic disease, he went to study medicine at Jena, where he graduated in 1681. The year following he published an excellent tract "De Cinnabari Antimonii," which gained him great applause, and numerous pupils to attend a course of chemical lectures, which he delivered there. He then practised his profession for two years at Minden with very good success; and after travelling to Holland and England, where he received many marks of distinction, he was appointed, on his return in 1685, physician to the garrison, and subsequently to Frederic William, elector of Brandenburgh, and the whole principality of Minden. He was, however, induced to settle in 1688 as public physician at Halberstadt; where he published a treatise, "De Insufficientia Acidi et Viscidi." An university being founded at Halle, by Frederic III., afterwards first King of Prussia, Hoffman was appointed in 1693, primary professor of Medicine, and composed the Statutes of that institution, and recommended Stahl as his colleague. He was most active in his professional duties; and by the eloquence and learning displayed in his lectures and publications, he extended his own reputation, and that of the new university. He was admitted into the scientific societies at Berlin, Petersburgh, and London; and had the honour of attending many of the German Courts as physician. Haller asserts that he acquired great wealth by the sale of various chemical nostrums. He examined many of the mineral waters in Germany, particularly those of Seidlitz, which he first introduced to public notice in 1717. The year after he commenced the publication of his "Medicina Rationalis Systematica," which was received with great applause by the faculty in various parts of Europe, and is said to have occupied him nearly twenty years. He also published two volumes of "Consultations," and three books of select chemical observations. In 1727, he was created Count Palatine by the Prince of Swartzenburgh, whom he carried through a dangerous disease. About seven years after, he attended Frederic William, King of Prussia, and is said by dignified remonstrance to have secured himself against the brutal rudeness shown by that monarch to those about him; he was ultimately distinguished with great honours, and invited strongly to settle at Berlin, but declined it on account of his advanced age. He continued to perform his duties at Halle till 1742, in which year he died. Hoffman was a very voluminous writer. His works have been collected in six folio volumes, printed at Geneva. They contain a great mass of valuable practical matter, partly original, but detailed in a prolix manner, and intermixed with much hypothesis. He has the merit, however, of first turning the attention of practitioners to the morbid affections of the nervous system, instead of framing mere mechanical or chemical theories: but he did not carry the doctrine to its fullest extent, and retained some of the errors of the humoral pathology. He pursued the study of chemistry and pharmacy with considerable ardour; but his practice was cautious, particularly in advanced age, trusting much to vegetable simples.

Hog's fennel. See *Peucedanum.*

Ho′lcimos. (From ελκω, to draw.) It sometimes means a tumour of the liver.

HO′LCUS. 1. The name of a genus of plants in the Linnæan system. Class, *Polygamia;* Order, *Monœcia.*

2. The Indian millet-seed, which is said to be nutritive.

Holcus sorgum. Guinea corn.

HOLERACEUS. See *Oleraceous.*

Hollow leaf. See *Concavus.*

HOLLY. See *Ilex.*

Holly, knee. See *Ruscus.*

Holly, sea. See *Eryngium.*

Holmi′scus. (Dim. of ολμος, a mortar.)

1. A small mortar.

2. The cavity of the large teeth, because they pound the food as in a mortar.

HOLMITE. A new mineral, composed of lime, carbonic acid, alumina, silica, oxide of iron, and water.

Holophly′ctides. (From ολος, whole, and φλυκτις, a pustule.) Little pimples all over the body.

HOLO'STES. See *Holosteus.*

HOLO'STEUM. See *Holosteus.*

HOLO'STEUS. (From ολος, whole, and οστεον, a bone.) Glue-bone. See *Osteocolla.*

HOLOTO'NICUS. (From ολος, whole, and τεινω, to stretch.) A term formerly applied to diseases accompanied with universal convulsion, or rigor.

HOLY THISTLE. See *Centaurea benedicta.*

HOLYWELL. There is a mineral water at this place arranged under the class of simple cold waters, remarkable for its purity. It possesses similar virtues to that of Malvern. See *Malvern water.*

HO'MA. An anasarcous swelling.

Homberg's phosphorus. Ignited muriate of lime.

Homberg's salt. See *Boracic acid.*

HOMOGENEOUS. (*Homogeneus;* from ομος, like, and γενος, a kind.) Uniform, of a like kind or species, of the same quality. A term used in contradistinction to *heterogeneous*, when the parts of the body are of different qualities.

HOMOPLA'TA. (From ωμος, the shoulder, and πλατα, the blade.) See *Scapula.*

HONEY. See *Mel.*

HONEY-STONE. Mellite. Crystalhartz of Mohs. Pyramidal honey-stone of Jameson. This is of a honey colour, distinctly crystallized, and occurs on bituminous wood and earth coal, and is usually accompanied with sulphur at Artern, in Thuringia.

HONEY-SUCKLE. See *Lonicera periclymenum.*

Hooded leaf. See *Cucullatus.*

HOOPING-COUGH. See *Pertussis.*

HOP. See *Humulus lupulus.*

HOPLOCHRI'SMA. (From οπλον, a weapon, and χρισμα, a salve.) A salve which was ridiculously said to cure wounds by consent; that is, by anointing the instrument with which the wound was made.

HORDE'OLUM. (Diminutive of *hordeum*, barley.) A little tumour on the eyelids, resembling a barley-corn. A stye. Scarpa remarks, the stye is strictly only a little boil, which projects from the edge of the eye-lids, mostly near the great angle of the eye. This little tumour, like the furunculus, is of a dark red colour, much inflamed, and a great deal more painful than might be expected, considering its small size. The latter circumstance is partly owing to the vehemence of the inflammation producing the stye, and partly to the exquisite sensibility and tension of the skin, which covers the edge of the eye-lids. On this account, the hordeolum very often excites fever and restlessness in delicate, irritable constitutions; it suppurates slowly and imperfectly; and, when suppurated, has no tendency to burst.

The stye, like other furunculous inflammations, forms an exception to the general rule, that the best mode in which inflammatory swellings can end, is resolution; for, whenever a furunculous inflammation extends so deeply as to destroy any of the cellular substance, the little tumour can never be resolved, or only imperfectly so. This event, indeed, would rather be hurtful, since there would still remain behind a greater or smaller portion of dead cellular membrane; which sooner or later, might bring on a renewal of the stye, in the same place as before, or else become converted into a hard indolent body, deforming the edge of the eye-lid.

HO'RDEUM. (*Ab horrore aristæ;* from the unpleasantness of its beard to the touch.) 1. The name of a genus of plants in the Linnæan system. Class, *Triandria;* Order, *Digynia.* Barley.

2. The pharmacopœial name of the common barley. See *Hordeum vulgare.*

HORDEUM CAUSTICUM. See *Cevadilla.*

HORDEUM DISTICHON. This plant affords the barley in common use. See *Hordeum vulgare.*

HORDEUM PERLATUM. See *Hordeum vulgare.*

HORDEUM VULGARE. The systematic name of the common barley. The seed called barley is obtained from several species of *hordeum*, but principally from the *vulgare*, or common or Scotch barley, and the *distichon*, or *hordeum gallicum vel mundatum*, or French barley, of Linnæus. It is extremely nutritious and mucilaginous, and in common use as a drink, when boiled, in all inflammatory diseases and affections of the chest, especially where there is cough or irritation about the fauces. A decoction of barley with gum, is considered a useful diluent and demulcent in dysury and strangury; the gum mixing with the urine, sheaths the urinary canal from the acrimony of the urine. Among the ancients, decoctions of barley, κριθη, were the principal medicine, as well as aliment, in acute diseases. Barley is freed from its shells in mills, and in this state called Scotch and French barley. In Holland, they rub barley into small round grains, somewhat like pearls, which is therefore called *pearl barley*, or *hordeum perlatum.*

HOREHOUND. See *Marrubium.*

HORIZONTALIS. Horizontal: applied to leaves, roots, &c. which spread in the greatest possible degree; as the leaves of *Gentiana campestris*, and roots of the *Laserpitium prutenicum.*

HO'RMINUM. (From ορμαω, to incite: named from its supposed qualities of provoking venery.) See *Salvia sclarea.*

HORN. An animal substance, chiefly membraneous, composed of coagulated albumen, with a little gelatin, and about half a per cent. of phosphate of lime. The horns of the buck and hart are of a different nature, being intermediate between bone and horn. See *Cornu.*

Horn silver. A chloride of silver.

HORNBLENDE. A sub-species of straight-edged augite. There are three varieties of it:

1. *Common hornblende*, which is of a greenish black colour: is an essential ingredient of the mountain rocks, syenite and green stone, and occurs frequently in granite, gneiss, &c. It is found abundantly in the British isles, and on the Continent.

2. *Hornblende slate*, of a colour intermediate between green and black. It occurs in beds of gneiss in many parts of Scotland, England, and the Continent.

3. *Basaltic hornblende*, of a velvet black colour. It is found embedded in basalt, along with olivine and augite, at Arthur's Seat, near Edinburgh, and in basaltic rocks of England, Ireland, and the Continent.

HORNSTONE. Professor Jameson's ninth sub-species of rhomboidal quartz.

HORRIPILA'TIO. Horripilation. (From *horror*, and *pilus*, a hair.) A shuddering or a sense of creeping in different parts of the body. A symptom of the approach of fever.

Horse-chesnut. See *Æsculus hippocastanum.*

Horse-raddish. See *Cochlearia armoracia.*

HORSE-TAIL. See *Hippurus vulgaris.*

HORSTIUS, GREGORY, was born at Torgau,

in 1578. After studying in different parts of Germany and Switzerland, he graduated at Basil in 1606, and was soon after appointed to a medical professorship at Wittenburg. But two years after he received a similar appointment at Giessen, and was made chief physician of Hesse; where he attained considerable reputation in his profession. In 1722 he went to Ulm, on an invitation from the magistracy as public physician and president of the college; where his learning, skill, and humanity, procured him general esteem. He died in 1636. His works were collected by his sons in three folio volumes.

HO'RTUS. (From *orior*, to rise, as being the place where vegetables grow up.) 1. A garden.

2. The genitals of a woman, which is the repository of the human semen.

Hortus siccus. A collection of dried plants.

HOUNDS-TONGUE. See *Cynoglossum.*

HOUSE-LEEK. See *Sempervivum tectorum.*

HUBER, John James, was born at Basle in 1707, and graduated there at the age of 26, after studying under the celebrated Haller and other able teachers. Two years after he was appointed physician to the Court of Baden Dourlach. He materially assisted Haller in his work on the Botany of Switzerland, and was consequently invited by him in 1738 to be dissector at Gottingen.

He speedily rose to considerable reputation there, and received different public appointments. He had likewise the honour of being elected into the most celebrated of the learned societies in Europe. He died in 1778. The chief objects of his research were the spinal marrow, and the nerves originating from it: he also inquired into the supposed influence of the imagination of the mother on the fœtus, and into the cause of miscarriages.

HULME, Nathaniel, was born at Halifax, in Yorkshire, 1732, and bred to the profession of a surgeon-apothecary. After serving some time in the navy, he graduated at Edinburgh in 1765. He then settled in London, and was soon after appointed physician to the General Dispensary, the first institution of that kind established in the metropolis. About the year 1775 he was elected physician to the Charter-house. In 1807 he died, in consequence of a severe bruise by a fall. He was author of several dissertations on scurvy, puerperal fever, &c. He also made a series of experiments on the light spontaneously emitted from various bodies, published in the Philosophical Transactions: and he was one of the editors of the London Practice of Physic.

HUMECTA'NTIA. (From *humecto*, to make moist.) Medicines which are supposed capable of softening by making the solids of the body moist.

HUMERAL. *Humeralis.* Belonging to the humerus or arm.

Humeral artery. *Arteria humeralis.* Brachial artery. The axillary artery, having passed the tendon of the great pectoral muscle, changes its name to the brachial or humeral artery, which name it retains in its course down the arm to the bend, where it divides into the radial and ulnar arteries. In this course it gives off several muscular branches, three of which only deserve attention: 1. *The arteria profunda superior*, which goes round the back of the arm to the exterior muscle, and is often named the upper muscular artery. 2. Another like it, called *arteria profunda inferior*, or the lower muscular artery. 3. *Ramus anastomoticus major*, which anastomoses round the elbow with the branches of the ulnar artery.

Humeralis musculus. See *Deltoides.*

HU'MERUS. (From ωμος, the shoulder.)

1. The arm, as composed of hard and soft parts, from the shoulder to the fore-arm.

2. The shoulder.

3. The bone of the arm, or *os humeri, os brachii.* A long cylindrical bone, situated between the scapula and fore-arm. Its upper extremity is formed somewhat laterally and internally, into a large, round, and smooth head, which is admitted into the glenoid cavity of the scapula. Around the basis of this head is observed a circular fossa, deepest anteriorly and externally, which forms what is called the neck of the bone, and from the edge of which arises the capsular ligament, which is further strengthened by a strong membraneous expansion, extending to the upper edge of the glenoid cavity, and to the coracoid process of the scapula; and likewise by the tendinous expansions of the muscles, inserted into the head of the humerus. This capsular ligament is sometimes torn in luxation, and becomes an obstacle to the easy reduction of the bone. The articulating surface of the head is covered by a cartilage, which is thick in its middle part, and thin towards its edges; by which means it is more convex in the recent subject than in the skeleton. This upper extremity, besides the round smooth head, affords two other smaller protuberances. One of these, which is the largest of the two, is of an irregular oblong shape, and is placed at the back of the head of the bone, from which it is separated by a kind of groove, that makes a part of the neck. This tuberosity is divided, at its upper part, into three surfaces; the first of these, which is the smallest and uppermost, serves for the insertion of the supraspinatus muscle; the second or middlemost, for the insertion of the infraspinatus; and the third, which is the lowest and hindmost, for the insertion of the teres minor. The other smaller tuberosity is situated anteriorly, between the larger one and the head of the humerus, and serves for the insertion of the subscapularis muscle. Between these two tuberosities there is a deep groove for lodging the tendinous head of the biceps brachii; the capsular ligament of the joint affording here a prolongation, thinner than the capsule itself, which covers and accompanies this muscle to its fleshy portion, where it gradually disappears in the adjacent cellular membrane. Immediately below its neck, the os humeri begins to assume a cylindrical shape, so that here the body of the bone may be said to commence. At its upper part is observed a continuation of the groove for the biceps, which extends downwards, about the fourth part of the length of the bone in an oblique direction. The edges of this groove are continuations of the greater and lesser tuberosities, and serve for the attachment of the pectoralis, latissimus dorsi, and teres major muscles. The groove itself is lined with a glistening substance like cartilage, but which seems to be nothing more than the remains of tendinous fibres. A little lower down, towards the external and anterior side of the middle of the bone, it is seen rising into a rough ridge for the insertion of the deltoid muscle. On each side of this ridge the bone is smooth, and flat, for the lodgment of the brachialis internus muscle; and behind the middle part of the outermost side of the ridge is a channel, for the transmission of vessels into the substance of the bone. A little lower down, and near the inner side of the ridge, there is sometimes seen such

another channel, which is intended for the same purpose. The os humeri, at its lower extremity, becomes gradually broader and flatter, so as to have this end nearly of a triangular shape. The bone, thus expanded, affords two surfaces, of which the anterior one is the broadest, and somewhat convex; and the posterior one narrower and smoother. The bone terminates in four large processes, the two outermost of which are called *condyles*, though not designed for the articulation of the bone. These condyles, which are placed at some distance from each other, on each side of the bone, are rough and irregular protuberances, formed for the insertion of muscles and ligaments, and differ from each other in size and shape. The external condyle, when the arm is in the most natural position, is found to be placed somewhat forwarder than the other. The internal condyle is longer, and more protuberant, than the external. From each of these processes, a ridge is continued upwards, at the side of the bone. In the interval between the two condyles are placed the two articulating processes, contiguous to each other, and covered with cartilage. One of these, which is the smallest, is formed into a small, obtuse, smooth head, on which the radius plays. This little head is placed near the external condyle, as a part of which it has been sometimes described. The other, and larger process, is composed of two lateral protuberances and a middle cavity, all of which are smooth and covered with cartilage. From the manner in which the ulna moves upon this process, it has gotten the name of *trochlea*, or pulley. The sides of this pulley are unequal; that which is towards the little head is the highest of the two; the other, which is contiguous to the external condyle, is more slanting, being situated obliquely from within outwards, so that when the fore-arm is fully extended, it does not form a straight line with the os humeri, and, for the same reason, when we bend the elbow, the hand comes not to the shoulder, as it might be expected to do, but to the forepart of the breast. There is a cavity at the root of these processes, on each of the two surfaces of the bone. The cavity on the anterior surface is divided by a ridge into two, the external of which receives the end of the radius, and the internal one lodges the coronoid process of the ulna in the flexions of the fore-arm. The cavity on the posterior surface, at the basis of the pulley, is much larger, and lodges the olecranon when the arm is extended. The internal structure of the os humeri is similar to that of other long bones. In new-born infants, both the ends of the bone are cartilaginous, and the large head, with the two tubercles above, and the condyles, with the two articulating processes below, become epiphyses before they are entirely united to the rest of the bone.

HU'MILIS. (From *humi*, on the ground: so named because it turns the eye downwards, and is expressive of humility.) See *Rectus inferior oculi*.

HUMITE. A mineral of a reddish brown colour found near Naples, and named by Count Bournon in honour of Sir Abraham Hume, a distinguished cultivator of mineralogy.

HU'MOR. (*Ab humo*, from the ground; because moisture springs from the earth.) Humour, a general name for any fluid of the body except the blood.

HUMOR VITREUS. The vitreous humour of the eye, which takes its name from the resemblance to melted glass, is less dense than the crystalline, but more than the aqueous humour; it is very considerable in the human eye, and seems to be formed by the small arteries that are distributed in cells of the hyaloid membrane; it is heavier than common water, slightly albuminous and saline.

HUMOUR. See *Humor*.

Humour, aqueous. See *Aqueous humour.*

Humour, vitreous. See *Humor vitreus.*

Humours of the Eye. See *Eye.*

HUMULIN. The narcotic principle of the fruit of the hop. See *Humulus*.

HU'MULUS. (From *humus*, the ground: so named because, without factitious support, it creeps along the ground.) The name of a genus of plants in the Linnæan system. Class, *Diœcia;* Order, *Pentandria.* The hop.

HUMULUS LUPULUS. The systematic name of the hop-plant. *Lupulus; Convolvulus perennis.* The hop is the floral leaf or bractea of this plant: it is dried and used in various kinds of strong beer. Hops have a bitter taste, less ungrateful than most of the other strong bitters, accompanied with some degree of warmth and aromatic flavour, and are highly intoxicating. The hop-flower also exhales a considerable quantity of its narcotic power in drying; hence those who sleep in the hop houses are with difficulty roused from their slumber. A pillow stuffed with these flowers is said to have laid our late monarch to sleep when other remedies had failed. The young sprouts, called hop-tops, if plucked when only a foot above the ground, and boiled, are eaten, like asparagus, and are a wholesome delicacy. The active or narcotic principle of the hop, is called *humulin*.

HUNGER. *Fames.* "The want of solid aliments is characterised by a peculiar sensation in the region of the stomach, and by a general feebleness, more or less marked. This feeling is generally renewed after the stomach has been for some time empty; it is variable in its intensity and its nature in different individuals, and even in the same individual. In some its violence is excessive, in others it is scarcely felt; some never feel it, and eat only because the hour of repast is come. Many persons perceive a drawing, a pressure more or less painful in the epigastric region, accompanied by yawnings, and a particular noise, produced by the gases contained in the stomach, which becomes contracted. When this want is not satisfied it increases, and may become a severe pain: the same takes place with the sensation of weakness and general fatigue, which is felt, and which may increase, so as to render the motions difficult, or even impossible.

Authors distinguish in hunger, local phenomena, and general phenomena.

This distinction is good in itself, and may be useful for study; but have not mere gratuitous suppositions been described as local or general phenomena of hunger, the existence of which was rendered probable by this theory? This point of physiology is one of those in which the want of direct experiment is the most strongly felt. The pressure and contraction of the stomach are considered among the local phenomena of hunger: 'the sides of that viscus,' it is said, 'become thicker; it changes its form and situation, and draws the duodenum a little towards it; its cavity contains saliva mixed with air, mucosities, bile, which has regurgitated in consequence of the dragging of the duodenum; the quantity of these humours increases in the stomach in proportion as hunger is of longer continuation. The cystic bile does not flow into the duodenum; it collects in the gall-bladder, and it becomes abundant and black according to the continuance of abstinence. A change takes place in the order of the circulation of the digestive organs; the stomach receives less blood, perhaps on account of the flexion of these vessels which is then greater; perhaps by the compression of the nerves, in consequence of this confinement, the influence of which upon the circulation will then be diminished. On the other hand, the liver, the spleen, the epiploon, receive more, and perform the office of *diverticula*: the liver and the spleen, because they are less supported when the stomach is empty, and then present a more easy access to the blood; and the epiploon, because the vessels are then less *flexuous*,' &c. The most of these data are mere conjectures, and nearly devoid of proof. After twenty-four, forty-eight, and even sixty hours of complete abstinence, Dr. Magendie says he never saw the contraction and pressure of the stomach of which some authors speak: this organ has always presented to him very considerable dimensions, particularly in its splenic extremity; it was only after the fourth and fifth day that it appeared to return upon itself, to diminish much in size, and slightly in position; even these effects are not strongly marked unless fasting has been very strictly observed.

Bichât thinks that the pressure sustained by the empty stomach is equal to that which it supports when distended by aliments, since, says he, the sides of the abdomen are compressed in proportion as the volume of the stomach diminishes. The contrary of this may be easily proved by putting one or two fingers into the abdominal cavity, after having made an incision in its sides; it will then be easily seen that the pressure sustained by the viscera, is in a certain degree, in direct proportion to the distension of the stomach; if the stomach is full, the finger will be stronger pressed, and the viscera will press outward to escape through the opening; if it is empty, the pressure will be very trifling, and the viscera will have little tendency to pass out from the abdominal cavity. It must be understood that in this experiment the pressure exerted by the abdominal muscles, when they are relaxed, ought not to be confounded with that which they exert when contracted with force. Also, when the stomach is empty, all the reservoirs contained in the abdomen are more easily distended by the matters which remain some time in them. Perhaps this is the principal reason why bile then accumulates in the gall-bladder. With regard to the presence of bile in the stomach, that some persons regard as the cause of hunger, unless in certain sickly cases bile does not enter it, though it continues to flow into the small intestine.

The quantity of mucus that the cavity of the stomach presents is so much greater in proportion to the prolongation of abstinence.

Relatively to the quantity of blood which goes to the stomach when empty, in proportion to the volume of its vessels, and the mode of circulation which then exists, the general opinion is that it receives less of this fluid than when it is full of aliments; but, far from being in this respect in opposition with the other abdominal organs, this disposition appears to be common to all the organs contained in the abdomen.

To the general phenomena of hunger is ascribed a weakness and diminution of the action of all the organs; the circulation and the respiration become slow, the heat of the body lowers, the secretions diminish, the whole of the functions are exerted with more difficulty. The absorption alone is said to become more active, but nothing is strictly demonstrated in this respect.

Hunger, appetite itself, which is only its first degree, ought to be distinguished from that feeling which induces us to prefer one sort of food to another, from that which causes us, during a repast, to choose one dish rather than another, &c.

These feelings are very different from real hunger, which expresses the true wants of the economy; they in a great measure depend on civilization, on habits and certain ideas relative to the properties of aliments. Some of them are in unison with the season, the climate, and then they are equally legitimate as hunger itself; such is that which inclines us to a vegetable regimen in hot countries, or during the heats of summer.

Certain circumstances render hunger more intense, and cause it to return at nearer intervals: such as a cold and dry air, winter, spring, cold baths, dry frictions upon the skin, exercise on horse-back, walking, bodily fatigue, and generally all the causes that put the action of the organs in play, and accelerate the nutritive process with which hunger is essentially connected. Some substances, being introduced into the stomach, excite a feeling like hunger, but which ought not to be confounded with it.

There are causes which diminish the intensity of hunger, and which prolong the periods at which it habitually manifests itself: among this number are the inhabiting of hot countries, and humid places, rest of the body and mind, depressing passions, and indeed all the circumstances that interrupt the action of the organs, and diminish the activity of nutrition. There are also substances which, being brought into the digestive canals, prevent hunger, or cause it to cease, as opium, hot drinks, &c.

With respect to the cause of hunger, it has been, by turns, attributed to the providence of the vital principle, to the frictions of the sides of the stomach against each other, to the dragging of the liver upon the diaphragm, to the action of bile upon the stomach, to the acrimony and acidity of the gastric juice, to fatigue of the contracted fibres of the stomach, to compression of the nerves of this viscus, &c. &c.

Hunger arises, like all other internal sensations, from the action of the nervous system; it has no other seat than this system itself, and no other causes than the general laws of organization. What very well proves the truth of this assertion is, that it sometimes continues though the stomach is filled with food; that it cannot be produced though the stomach has been some time empty; lastly, that it is so subject to habit as to cease spontaneously after the habitual hour of repast is over. This is true not only of the feeling which takes place in the region of the stomach, but also of the general weakness that accompanies it, and which, consequently, cannot be considered as real, at least in the first instant in which it is manifested."

HUNTER, William, was born in 1718, at Kilbride in Scotland. He was educated for the church at Glasgow; but feeling scruples against subscription, and having become acquainted with the celebrated Cullen, he determined to pursue the medical profession. After living three years with that able teacher, who then practised as a surgeon apothecary at Hamilton, he went to Edinburgh in November 1740; and in the following summer came to London with a recommendation to Dr. James Douglas, who engaged him to assist in his dissections, and superintend the education of his son. He was also enabled by that physician's liberality to attend St. George's Hospital, and other teachers; but death deprived him of so valuable a friend within a year. However, he remained in the family, and prosecuted his studies with great zeal. In 1743, he communicated to the Royal Society a paper on the structure and diseases of articulating cartilages, which was much admired. He now formed the design of teaching anatomy; and, after encountering some difficulties, commenced by giving a course on the operations of surgery to a society of navy surgeons in lieu of Mr. Samuel Sharpe. At first he felt considerable solicitude in speaking in public; but gradually this wore off, and he evinced a remarkable facility in expressing himself with perspicuity and elegance. He gave so much satisfaction, that he was requested to extend the plan to anatomy, which he began accordingly in 1746. His success was considerable, but having somewhat embarrassed himself at first by assisting his friends, he was obliged to adopt proper caution in lending money; which, with his talents, industry, and economy, enabled him to acquire an ample fortune. In 1748, he accompanied his pupil, young Douglas, on a tour, and having seen the admirable injections of Albinus at Leyden, he was inspired with a strong emulation to excel in that branch. On his return he relinquished the profession of surgery, and devoted himself to midwifery, to which his person and manners well adapted him; and having been appointed to the Middlesex and British lying-in hospitals, as well as favoured by other circumstances, he made a rapid advance in practice. In 1750 he obtained a doctor's degree from Glasgow, and was afterwards often consulted as a physician in cases, which required peculiar anatomical skill. Six years after he was admitted a licentiate of the College in London; and also a member of the society, by which the "Medical Observations and Enquiries" were published. He enriched that work with many valuable communications; particularly an account of the disease, since called Aneurismal Varix, a case of emphysema, with practical remarks, wherein he showed the fat to be deposited in distinct vesicles; and some observations on the retroversion of the uterus: and on the death of Dr. Fothergill, he was chosen president of that society. In 1762 he published his "Medical Commentaries," in which he laid claim, with much asperity, to several anatomical discoveries, especially relative to the absorbent system, in opposition to the second Monro of Edinburgh. He was extremely tenacious of his rights in this respect, and would not allow them to be infringed even by his own brother. It must be very difficult, and of little importance, to decide such controversies; especially as the principal points concerning the absorbent system had been stated as early as 1726, in a work printed at Paris by M. Noguez. About the same period, the Queen being pregnant, Dr. Hunter was consulted; and two years after he was appointed her physician extraordinary. In 1767 he was chosen a fellow of the Royal Society, to which he communicated some papers; and in the year following he was appointed by the King professor of Anatomy to the Royal Academy on its first institution; he was also elected into the society of Antiquaries, and some respectable foreign associations. In 1775 he published a splendid work, which had occupied him for 24 years previously, "The Anatomy of the Gravid Uterus," illustrated by plates, admirable for their accuracy, as well as elegance; among other improvements, the membrana decidua reflexa, discovered by himself, was here first delineated. He drew up a detailed description of the figures; which was published after his death by his nephew, Dr. Baillie. Another posthumous publication, deservedly much admired, was the "Two Introductory Lectures" to his anatomical course. As his wealth increased, he formed the noble design of establishing an anatomical school; and proposed to government, on the grant of a piece of ground, to build a proper edifice, and endow a perpetual professorship: but this not being acceded to, he set about the establishment in Great Windmill-street, where he collected a most valuable museum of anatomical preparations, subjects of natural history, scarce books, coins, &c. to which an easy access was always given. He continued to lecture and practise till near the period of his death in 1783. He bequeathed the use of his museum for 30 years to Dr. Baillie; after which it was to belong to the University of Glasgow.

HUNTER, JOHN, was born ten years after his brother William. His early education was much neglected, and his temper injured, through his mother's indulgence. At a proper age he was put under a relation, a carpenter and cabinet-maker, who failed in his business. Hearing at this period of his brother's success, he applied to become his assistant, and accordingly came to London in the autumn of 1748. He made such proficiency in dissection, that he was capable of undertaking the demonstrations in the following season. During the summer he attended the surgical practice at different hospitals; and in 1756 he was appointed house-surgeon at St. George's. He had been admitted by his brother to a partnership in the lectures the year before. After labouring about ten years with unexampled ardour in the study of human anatomy, he turned his attention to that of other animals, with a view to elucidate physiology. His health was so much impaired by these pursuits, that in 1760 he went abroad as surgeon on the staff, and thus acquired a knowledge of gun-shot wounds. On his return after three years, he settled in London as a surgeon, and gave instructions in dissection and the performance of operations; and he continued, with great zeal, his researches into comparative anatomy, and natural history. Several papers were communicated by him to the Royal Society of which he was elected a member in 1767. About this time, by his brother's interest, he was appointed one of the surgeons at St. George's Hospital; and his professional reputation was rapidly increasing. In 1771 he published the first part of his work on the teeth, displaying great accuracy of research: and two years after he began a course of lectures on the principles of surgery. He fell short of his brother in methodical arrangement, and facility of expressing his ideas, and indeed adopted a peculiar language, perhaps in part from the deficiency of his education; but he certainly brought forward many ingenious speculations in physiology and pathology, and suggested some important practical improvements, particularly the operation for popliteal aneurism. In 1776 he was appointed surgeon-extraordinary to the King; and soon after received marks of distinction from several foreign societies. His emoluments increasing, he took a large house in Leicester-square, and built a spacious museum, which he continued to store with subjects in comparative anatomy, at a very great expence. The post of Deputy-Surgeon-General to the army was conferred upon him in 1786; and in the same year his great work on the venereal disease appeared, which will ever remain a monument to his extraordinary sagacity and talent for observation. He also published at this period "Observations on the Animal Œconomy," chiefly composed of papers already printed in the Philo sophical Transactions. In 1790 he was appointed Inspector-General of Hospitals, and Surgeon-General to the army; when he resigned his lectures to Mr. Home, whose sister he had married. He had been for two years before labouring under symptoms of organic disease about the heart, which were aggravated by any sudden exertion, or agitation of his mind; these increased progressively, and in October 1793, while at the hospital, being vexed by some untoward circumstance, he suddenly expired. He left a valuable treatise on the blood, inflammation, and gun-shot wounds, which was published soon after with a life prefixed, by his brother-in-law. His museum was directed to be offered to the purchase of Government: it was bought for 15,000*l.* and presented to the college of Surgeons, on condition of their opening it to public inspection, and giving a set of lectures annually explanatory of its contents. The preparations are arranged so as to exhibit all the gradations of nature, from the simplest state of animated existence up to man, according to the different functions. It comprehends also a large series of entire animals, skeletons of almost every genus, and other subjects of natural history.

HURTSICKLE. (So called because it is troublesome to cut down, and sometimes notches the sickle. See *Centaurea cyanus*.

HUSK. See *Gluma*.

HUXHAM, JOHN, was born about the end of the 17th century, and practised as a physician, with considerable reputation, at Plymouth, where he died in 1768. His writings display great learning and talent for observation. He kept a register of the weather and prevailing diseases for nearly thirty years, which was published in Latin, in three volumes. He was early elected into the Royal Society, and communicated several papers on pathology and morbid anatomy. But his fame rests chiefly upon his "Essay on Fevers," which went through several editions; a dissertation being afterwards added on the malignant sore throat.

HYACINTH. 1. A sub-species of pyramidal zircon. It comes from Ceylon, and is much esteemed as a gem.

2. See *Hyacinthus*.

HYACI'NTHUS. (Said by the poets to be named from the friend of Apollo, who was turned into this flower.) The name of a genus of plants. Class, *Hexandria*; Order, *Monogynia*.

HYACINTHUS MUSCARI. *Muscari.* The systematic name of the musk-grape flower, which, according to Ray, possesses emetic and diuretic qualities.

HYACINTHUS NON SCRIPTUS. Hare-bells. The systematic name of the blue-bells, so common in our hedge in spring. The roots are bulbous; the flowers agreeably scented. Galen considered the root as a remedy in jaundice. It is ranked among the astringents, but of very inferior power.

HYALITE. A transparent silecious stone, which is often cut into ring-stones, found near Frankfort on the Maine.

HYALOI'DES. (*Membrana hyaloides*; from υαλος, glass, and ειδος, likeness.) *Membrana arachnoidea.* Capsule of the vitreous humour. The transparent membrane enclosing the vitreous humour of the eye.

HYBERNACULUM. This is defined by Linnæus to be a part of the plant which protects the embryo herb from external injuries.

An organic body which sprouts from the surface of different parts of a plant, enclosing the rudiments of the new shoot, and which is capable of evolving a new individual perfectly similar to the parent. This is a modification of the definition of Gærtner.—*Thompson.*

HYBOMA. A gibbosity of the spine.

HYBRID. (*Hybrida*, from υβρις, an injury; because its nature is tainted.) A monstrous production of two different species of animals or plants. In the former it is called mongrel, or mule. Neither the animal nor the seeds of hybrid plants propagate their species.

HYDA'RTHRUS. (From υδωρ, water, and αρθρον, a joint.) *Hydarthron. Hydarthros. Spina ventosa* of the Arabian writers, Rhazes and Avicenna. White-swelling. The white-swelling, in this country, is a peculiarly common and exceedingly terrible disease. The varieties of white-swelling are very numerous, and might usefully receive particular appellations. Systematic writers have generally been content with a distinction into two kinds, viz. *rheumatic* and *scrophulous*. The last species of the disease they also distinguish into such tumours as primarily affect the bones, and then the ligaments and soft parts; and into other cases, in which the ligaments and soft parts become diseased before there is any morbid affection of the bones.

These divisions, Mr. Samuel Cooper, in his Treatise on the Diseases of the Joints, proves to be not sufficiently comprehensive; and the propriety of using the term *rheumatic* he thinks to be very questionable.

The knee, ankle, wrist, and elbow, are the joints most subject to white-swellings. As the name of the disease implies, the skin is not at all altered in colour. In some instances, the swelling yields, in a certain degree, to pressure; but it never pits, and is almost always sufficiently firm to make an uninformed examiner believe that the bones contribute to the tumour. The pain is sometimes vehement from the very first; in other instances, there is hardly the least pain in the beginning of the disease. In the majority of scrophulous white-swellings, let the pain be trivial or violent, it is particularly situated in one part of the joint, viz. either *the centre of the articulation*, or the *head of the tibea*, supposing the knee affected. Sometimes the pain continues without interruption; sometimes there are intermissions; and in other instances the pain recurs at regular times, so as to have been called, by some writers, periodical. Almost all authors describe the patient as suffering more uneasiness in the diseased part, when he is warm, and particularly when he is in this condition in bed.

At the commencement of the disease, in the majority of instances, the swelling is very inconsiderable, or there is even no visible enlargement whatever. In the little depressions, naturally situated on each side of the patella, a fulness first shows itself, and gradually spreads all over the affected joint.

The patient unable to bear the weight of his body on the disordered joint, in consequence of the great increase of pain thus created, gets into the habit of only touching the ground with his toes: and the knee being generally kept a little bent in this manner, soon loses the capacity of becoming extended again. When white-swellings have lasted a while, the knee is almost always found in a permanent state of flexion. In scrophulous cases of this kind, pain constantly precedes any appearance of swelling: but the interval between the two symptoms differs very much in different subjects.

The morbid joint, in the course of time, acquires a vast magnitude. Still the integuments retain their natural colour, and remain unaffected.

The enlargement of the articulation, however, always seems greater than it really is, in consequence of the emaciation of the limb both above and below the disease.

An appearance of blue distended veins, and a shining smoothness, are the only alterations to be noticed in the skin covering the enlarged joint. The shining smoothness seems attributable to the distension, which obliterates the natural furrows and wrinkles of the cutis. When the joint is thus swollen, the integuments cannot be pinched up into a fold, as they could in the state of health, and even in the beginning of the disease.

As the distemper of the articulation advances, collections of matter form about the part, and at length burst. The ulcerated openings sometimes heal up; but such abscesses are generally followed by other collections, which pursue the same course. In some cases, these abscesses form a few months after the first affection of the joint; on other occasions, several years elapse, and no suppuration of this kind makes its appearance.

Such terrible local mischief must necessarily produce constitutional disturbance. The patient's health becomes gradually impaired; he loses both his appetite and natural rest and sleep; his pulse is small and frequent; and obstinate debilitating diarrhœa and profuse nocturnal sweats ensue. Such complaints are sooner or later followed by dissolution, unless the constitution be relieved in time, either by the amendment or removal of the diseased part. In different patients, however, the course of the disease, and its effects upon the system, vary very much in relation to the rapidity with which they occur.

Rheumatic white-swellings are very distinct diseases from the *scrophulous distemper* of large joints. In the first, the pain is said never to occur without being attended with swelling. Scrophulous white-swellings, on the other hand, are always preceded by a pain, which is particularly confined to one point of the articulation. In rheumatic cases, the pain is more general, and diffused over the whole joint.

With respect to the particular causes of all such white-swellings as come within the class of rheumatic ones, little is known. External irritation, either by exposure to damp or cold, or by the application of violence, is often concerned in bringing on the disease; but very frequently no cause of this kind can be assigned for the complaint. As for scrophulous white-swellings, there can be no doubt that they are under the influence of a particular kind of constitution, termed a *scrophulous* or *strumous* habit. In this sort of temperament, every cause capable of exciting inflammation, or any morbid and irritable state of a large joint, may bring such disorder as may end in the severe disease of which we are now speaking.

In a man of a sound constitution, an irritation of the kind alluded to might only induce common healthy inflammation of the affected joint.

In scrophulous habits, it also seems probable that the irritation of a joint is much more easily produced than in the other constitutions; and no one can doubt that, when once excited in scrophulous habits, it is much more dangerous and difficult of removal than in other patients.

HYDATID. (*Hydatis*; from ὕδωρ, water.) 1. A very singular animal, formed like a bladder, and distended with an aqueous fluid. These animals are sometimes formed in the natural cavities of the body, as the abdomen and ventricles of the brain, but more frequently in the liver, kidney, and lungs, where they produce diseased actions of those viscera. Cullen arranges these affections in the class *Locales*, and order *Tumores*. If the vires naturæ medicatrices are not sufficient to effect a cure, the patient mostly falls a sacrifice to their ravages. Dr. Baillie gives the following interesting account of the hydatids, as they are sometimes found in the liver:—'There is no gland in the human body in which hydatids are so frequently found as the liver, except the kidneys, where they are still more common. Hydatids of the liver are usually found in a cyst, which is frequently of considerable size, and is formed of very firm materials, so as to give to the touch almost the feeling of cartilage. This cyst, when cut into, is obviously laminated, and is much thicker in one liver than another. In some livers it is not thicker than a shilling, and in others it is near a quarter of an inch in thickness. The laminæ which compose it are formed of a white matter, and on the inside there is a lining of a pulpy substance, like the coagulable lymph. The cavity of the cyst, I have seen, in one instance, subdivided by a partition of this pulpy substance. In a cyst may be found one hydatid, or a greater number of them. They lie loose in the cavity, swimming in a fluid; or some of them are attached to the side of the cyst. They consist of a round bag, which is composed of a white, semi-opaque, pulpy matter, and contain a fluid capable of coagulation. Although the common colour of hydatids be white, yet I have occasionally seen some of a light amber colour. The bag of the hydatid consists of two laminæ, and possesses a good deal of contractile power. In one hydatid this coat, or bag, is much thicker and more opaque than in another; and even in the same hydatid, different parts of it will often differ in thickness. On the inside of an hydatid, smaller ones are sometimes found, which are commonly not larger than the heads of pins, but sometimes they are even larger in their size than a gooseberry. These are attached to the larger hydatid, either at scattered irregular distances, or so as to form small clusters; and they are also found floating loose in the liquor of the larger hydatids. Hydatids of the liver are often found unconnected with each other; but sometimes they have been said to enclose each other in a series, like pill-boxes. The most common situation of hydatids of the liver is in its substance, and enclosed in a cyst; but they are occasionally attached to the outer surface of the liver, hanging from it, and occupying more or less of the general cavity of the abdomen. The origin and real nature of these hydatids are not fully ascertained; it is extremely probable, however, that they are a sort of imperfect animalcules. There is no doubt at all, that the hydatids in the livers of sheep are animalcules; they have been often seen to move when taken out of the liver and put into warm water; and they retain this power of motion for a good many hours after a sheep has been killed. The analogy is great between hydatids in the liver of a sheep and those of the human subject. In both, they are contained in strong cysts, and in both they consist of the same white pulpy matter. There is undoubtedly some difference between them in simplicity of organization; the hydatid in the human liver being a simple uniform bag, and the hydatid in that of a sheep having a neck and mouth appendant to the bag. This difference need be no considerable objection to the opinion above stated. Life may be conceived to be attached to the most simple form of organization. In proof of this, hydatids have been found in the brains of sheep, resembling almost exactly those in the human liver, and which have been seen to move, and therefore are certainly known to be animalcules. The hydatids of the human liver, indeed have not, as far as I know, been found to move when taken out of the body and put into warm water; were this to have happened, no uncertainty would remain. It is not difficult to see a good reason why there will hardly occur any proper opportunity of making this experiment. Hydatids are not very often found in the liver, because it is not a very frequent disease there; and the body is allowed to remain for so long a time after death before it is examined, that the hydatids must have lost their living principle, even if they were animalcules, and it appears even more difficult to account for their production, according to the common theory of generation, than for that of intestinal worms. We do not get rid of the difficulty by asserting, that the hydatids in the human liver are not living animals, because in sheep they are certainly such, where the difficulty of accounting for their production is precisely the same."

2. The name of a tumour, the contents of which is a water-like fluid.

HYDERUS. (From *υδερος*, *ley-drops;* from *υδωρ*, water.) An increased flow of urine.

HY'DRAGOGUE. (*Hydragogus;* from ὓδωρ, water, and *αγω*, to drive out.) Medicines are so termed which possess the property of increasing the secretions or excretions of the body so as to cause the removal of water from any of its cavities, such as cathartics, &c.

HYDRARGYRATUS. Of or belonging to mercury.

HYDRA'RGYRUM. (Ὑδραργυρος; from *υδωρ*, water, and *αργυρος*, silver: so named from its having a resemblance to fluid silver.) *Hydrargyrus.* The name in the London Pharmacopœia, and other works, for mercury. See *Mercury.*

HYDRARGYRUM PRÆCIPITATUM ALBUM. White precipitated mercury. *Calx hydrargyri alba.* Take of oxymuriate of mercury, half a pound; muriate of ammonia, four ounces; solution of subcarbonate of potassa, half a pint; distilled water, four pints. First dissolve the muriate of ammonia, then the oxymuriate of mercury, in the distilled water, and add thereto the solution of subcarbonate of potassa. Wash the precipitated powder until it becomes tasteless; then dry it. It is only used externally, in the form of ointment, as an application in some cutaneous affections.

HYDRARGYRUM PURIFICATUM. Purified mercury. *Argentum vivum purificatum.* Take of mercury, by weight, six pounds; iron filings, a pound. Rub them together, and distil the mercury from an iron retort, by the application of heat to it. Purified quicksilver is somtimes administered in its metallic state, in doses of an ounce or more, in constipation of the bowels.

HYDRARGYRUS ACETATUS. *Mercurius acetatus; Pilulæ Keyseri.* By this preparation of mercury, the celebrated Keyser acquired an immense fortune in curing the venereal disease. It is an acetate of mercury, and therefore termed *hydrargyri acetas* in the new chemical nomenclature. The dose is from three to five grains. Notwithstanding the encomium given to it by some, it does not appear to be so efficacious as some other preparations of mercury.

HYDRARGYRUM CUM CRETA. Mercury with chalk. *Mercurius alkalizatus.* Take of purified mercury, by weight, three ounces; prepared chalk, five ounces. Rub them together, until the metallic globules disappear. This preparation is milder than any other mercurial except the sulphuret, and does not so easily act upon the bowels; it is therefore used largely by many practitioners, and possesses alterative properties in cutaneous and venereal complaints, in obstructions of the viscera, or of the prostate gland, given in the dose of ℈ss to ʒss, two or three times a day.

HYDRARGYRUS PHOSPHORATUS. This remedy has been observed to heal inveterate venereal ulcers in a very short time, nay, in the course of a very few days, particularly those about the pudenda. In venereal inflammations of the eyes, chancres, rheumatisms, and chronic eruptions, it has proved of eminent service. Upon the whole, if used with necessary precaution, and in the hands of a judicious practitioner, it is a medicine mild and gentle in its operation. The cases in which it deserves the preference over other mercurial preparations, are these: in an inveterate stage of syphilis, particularly in persons of torpid insensible fibres; in cases of exostosis, as well as obstructions in the lymphatic system; in chronic complaints of the skin. The following is the formula. ℞. Hydrargyri phosphorati, gr. iv. Corticis cinnamomi in pulverem triti, gr. xiv. Sacchari purif. ʒss. Misce. The whole to be divided into eight equal parts, one of which is to be taken every morning and evening, unless salivation takes place, when it ought to be discontinued. Some patients, however, will bear from one to two grains of the phosphate of quicksilver, without inconvenience.

HYDRARGYRUS PRECIPITATUS CINEREUS. This preparation is an oxide of mercury, and nearly the same with the *hydrargyri oxydum cinereum* of the London Pharmacopœia. It is used as an alterative in cases of pains arising from an admixture of rheumatism with syphilis. It may be substituted for the hydrargyrus sulphuratus ruber, in fumigating ozæna, and venereal ulcerated sore throat, on account of its not yielding any vapour offensive to the patient.

HYDRARGYRUS VITRIOLATUS. *Turpethum minerale; Mercurius emeticus flavus; Sulphas hydrargyri.* Formerly this medicine was in more general use than in the present day. It is a very powerful and active alterative when given in small doses. Two grains act on the stomach so as to produce violent vomitings. It is recommended as an errhine in cases of amaurosis. In combination with antimony it acts powerfully on the skin.

HYDRARGYRI NITRICO-OXYDUM. *Nitrico-oxydum hydrargyri; Hydrargyrus nitratus ruber; Mercurius corrosivus ruber; Mercurius præcipitatus corrosivus.* Nitric oxide of mercury. Red precipitate. Take of purified mercury, by weight, three pounds: of nitric acid, by weight, a pound and a half: of distilled water, two pints. Mix in a glass vessel, and boil the mixture in a sand bath, until the mercury be dissolved, the water also evaporated, and a white mass remain. Rub this into powder, and put it into another shallow vessel, then apply a moderate heat, and raise the fire gradually until red vapour shall cease to rise. This preparation is very extensively employed by surgeons as a stimulant and escharotic, but its extraordinary activity does not allow of its being given internally. Finely levigated and mixed with common cerates, it is an excellent application to indolent ulcers, especially those which remain after burns and scalds, and those in which the granulations are indolent and flabby. It is also an excellent caustic application to chancres.

HYDRARGYRI OXYDUM CINEREUM. *Oxydum hydrargyri nigrum.* The grey or black oxide of mercury. It has received several names;

Æthiops per se; Pulvis mercurialis cinereus; Mercurius cinereus; Turpethum nigrum; Mercurius præcipitatus niger. Take of submuriate of mercury, an ounce; lime-water, a gallon. Boil the submuriate of mercury in the lime-water, constantly stirring, until a grey oxide of mercury is separated. Wash this with distilled water, and then dry it. The dose from gr. ii. to x. There are four other preparations of this oxide in high estimation:

One made by rubbing mercury with mucilage of gum arabic. Plenk, of Vienna, has written a treatise on the superior efficacy of this medicine. It is very troublesome to make; and does not appear to possess more virtues than some other mercurial preparations. Another made by triturating equal parts of sugar and mercury together. The third, composed of honey or liquorice and purified mercury. The fourth is the blue mercurial ointment. All these preparations possess anthelmintic, antisyphilitic, alterative, sialagogue, and deobstruent virtues, and are exhibited in the cure of worms, syphilis, amenorrhœa, diseases of the skin, chronic diseases, obstructions of the viscera, &c.

HYDRARGYRI OXYDUM NIGRUM. See *Hydrargyri oxydum cinereum.*

HYDRARGYRI OXYDUM RUBRUM. *Oxydum hydrargyri rubrum; Hydrargyrus calcinatus.* Red oxide of mercury. Take of purified mercury, by weight, a pound. Pour the mercury into a glass mattrass, with a very narrow mouth and broad bottom. Apply a heat of 600° to this vessel, without stopping it, until the mercury has changed into red scales: then reduce these to a very fine powder. The whole process may probably require an exposure of six weeks. This preparation of mercury is given with great advantage in the cure of syphilis. Its action, however, is such, when given alone, on the bowels, as to require the addition of opium, which totally prevents it. It is also given in conjunction with opium and camphire, as a diaphoretic, in chronic pains and diseases of long continuance. It is given as an alterative and diaphoretic from gr. ss. to ii. every night, joined with camphor and opium, each gr. one-fourth or one-half. It is violently emetic, and cathartic in the dose of gr. iv. to gr. v.

HYDRARGYRI OXYMURIAS. *Oxymurias hydrargyri; Hydrargyrus muriatus.* Oxymuriate of mercury. Take of purified mercury by weight two pounds, sulphuric acid by weight thirty ounces, dried muriate of soda four pounds. Boil the mercury with the sulphuric acid in a glass vessel until the sulphate of mercury shall be left dry. Rub this, when it is cold, with the muriate of soda in an earthen-ware mortar; then sublime it in a glass cucurbit, increasing the heat gradually. An extremely acrid and violently poisonous preparation.

Given internally in small doses properly diluted, and never in the form of pill, it possesses antisyphilitic and alterative virtues. Externally, applied in form of lotion, it facilitates the healing of venereal sores, and cures the itch. In gargles for venereal ulcers in the throat, the oxymuriate of mercury gr. iii. or iv., barley decoction ℔j., honey of roses ℥ij., proves very serviceable; also in cases of tetters, from gr. v. to gr. x. in water ℔j.; and for films and ulcerations of the cornea, gr. i. to water ℥iv.

Mr. Pearson remarks, that "when the sublimate is given to cure the primary symptoms of syphilis, it will sometimes succeed; more especially, when it produces a considerable degree of soreness of the gums, and the common specific effects of mercury in the animal system. But it will often fail of removing even a recent chancre; and where that symptom has vanished during the administration of corrosive sublimate, I have known, says he, a three month's course of that medicine fail of securing the patient from a constitutional affection. The result of my observation is, that simple mercury, calomel or calcined mercury, are preparations more to be confided in for the cure of primary symptoms, than corrosive sublimate. The latter will often check the progress of secondary symptoms very conveniently, and I think it is peculiarly efficacious in relieving venereal pains, in healing ulcers of the throat, and in promoting the desquamation of eruptions. Yet even in these cases it never confers permanent benefit; for new symptoms will appear during the use of it; and on many occasions it will fail of affording the least advantage to the patient from first to last. I do, sometimes, indeed, employ this preparation in venereal cases; but it is either at the beginning of a mercurial course, to bring the constitution under the influence of mercury at an early period, or during a course of inunction, with the intention of increasing the action of simple mercury. I sometimes also prescribe it after the conclusion of a course of friction, to support the mercurial influence in the habit, in order to guard against the danger of a relapse. But on no occasion whatever, do I think it safe to confide in this preparation singly and uncombined for the cure of any truly venereal symptoms."

A solution of it is ordered in the pharmacopœia, termed *Liquor hydrargyri oxymuriatis.* Solution of oxymuriate of mercury. Take of oxymuriate of mercury, eight grains; distilled water, fifteen fluid ounces; rectified spirit, a fluid ounce. Dissolve the oxymuriate of mercury in the water, and add the spirit.

This solution is directed in order to facilitate the administration of divisions of the grain of this active medicine. Half an ounce of it contains one-fourth of a grain of the salt. The dose is from one drachm to half an ounce.

HYDRARGYRI SUBMURIAS. *Submurias hydrargyri.* Submuriate of mercury. *Calomelas.* Calomel. Take of oxymuriate of mercury, a pound; purified mercury, by weight, nine ounces. Rub them together until the metallic globules disappear, then sublime; take out the sublimed mass, and reduce it to powder, and sublime it in the same manner twice more successively. Lastly, bring it into the state of very fine powder by the same process which has been directed for the preparation of chalk. Submuriate, or mild muriate of mercury, is one of the most useful preparations of mercury. As an anti-venereal it is given in the dose of a grain night and morning, its usual determination to the intestines being prevented, if necessary, by opium. It is the preparation which is perhaps most usually given in the other diseases in which mercury is employed, as in affections of the liver, or neighbouring organs, in cutaneous diseases, chronic rheumatism, tetanus, hydrophobia, hydrocephalus, and febrile affections, especially those of warm climates. It is employed as a cathartic alone, in doses from v. to xii. grains, or to promote the operation of other purgatives. Its anthelmintic power is justly celebrated; and it is perhaps superior to the other mercurials in assisting the operation of diuretics in dropsy. From its specific gravity it ought always to be given in the form of a bolus or pill.

HYDRARGYRI SULPHURETUM NIGRUM. *Hydrargyrus cum sulphure.* Æthiop's mineral.

Take of purified mercury, sublimed sulphur, each a pound, by weight. Rub them together till the metallic globules disappear. Some suppose that the mercury is oxidized in this process, but that is not confirmed by the best experiments. The mercury, by this admixture of the sulphur, is deprived of its salivating power, and may be administered with safety to all ages and constitutions, as an anthelmintic and alterative.

Hydrargyri sulphuretum rubrum. Red sulphuret of mercury. *Hydrargyrus sulphuratus ruber; Minium purum; Minium Græcorum; Magnes epilepsiæ; Atzemafor; Amnion; Azamar.* Vitruvius calls it *anthrax.* A red mineral substance composed of mercury combined with sulphur. It is either native or factitious. The native is an ore of quicksilver moderately compact, and of an elegant striated red colour. It is found in the dutchy of Deuxponts, in the Palatinate, in Spain, South America, &c. It is called native vermilion, and cinnabar in flowers. The factitious is thus prepared: "Take of purified mercury, by weight, forty ounces; sublimed sulphur, eight ounces. Having melted the sulphur over the fire, mix in the mercury, and as soon as the mass begins to swell, remove the vessel from the fire, and cover it with considerable force to prevent inflammation; then rub the mass into powder and sublime." This preparation is esteemed a mild mercurial alterative, and given to children in small doses. Hoffman greatly recommends it as a sedative and antispasmodic. Others deny that cinnabar, taken internally, has any medicinal quality; and their opinion is grounded on the insolubility of it in any menstruum. In surgery its chief and almost only use is in the administration of quicksilver by fumigation. Thus employed it has proved extremely serviceable in venereal cases. Ulcers and excrescences about the pudendum and anus in women, are particularly benefited by it; and in these cases it is most conveniently applied by placing a red hot heater at the bottom of a night stool-pan, and after sprinkling on it a few grains of the red sulphuret of quicksilver, placing the patient on the stool. To fumigate ulcers in the throat, it is necessary to receive the fumes on the part affected, through the tube of a funnel. By enclosing the patient naked in a box, it has on some occasions been contrived to fumigate the whole body at once, and in this way the specific powers of the quicksilver have been very rapidly excited.

This mode of curing the lues venerea is spoken of as confirmed; and the subject has of late years been revived in a treatise by Sabonette, and by trials made in Bartholomew's hospital.

Mr. Pearson, from his experiments on mercurial fumigation, concludes, that where checking the progress of the disease suddenly is an object of great moment, and where the body is covered with ulcers or large and numerous eruptions, and in general to ulcers, fungi, and excrescences, the vapour of mercury is an application of great efficacy and utility; but that it is apt to induce a ptyalism rapidly, and great consequent debility, and that for the purpose of securing the constitution against a relapse, as great a quantity of mercury must be introduced into the system, by inunction, as if no fumigation had been employed.

HYDRATE. Hydroxure. Hydro-oxide. A compound of oxygen, in a definite proportion, with water.

HYDRELÆ'UM. (From *υδωρ*, water, and *ελαιον*, oil.) A mixture of oil and water.

HYDRENTEROCE'LE. (From *υδωρ*, water, *εντερον*, an intestine, and *κηλη*, a tumour.) A hydrocele, or dropsy of the scrotum, attended with a rupture.

HYDRIODATE. A salt consisting of the hydriodic acid, combined in a definite proportion with an oxide.

HYDRIODIC ACID. *Acidum hydriodicum.* A gaseous acid in its insulated state. "If four parts of iodine be mixed with one of phosphorus, in a small glass retort, applying a gentle heat, and adding a few drops of water from time to time, a gas comes over, which must be received in the mercurial bath. Its specific gravity is 4.4; 100 cubic inches, therefore, weigh 134.2 grs. It is elastic and invisible, but has a smell somewhat similar to that of muriatic acid. Mercury after some time decomposes it, seizing its iodine, and leaving its hydrogen, equal to one-half the original bulk, at liberty. Chlorine, on the other hand, unites to its hydrogen, and precipitates the iodine. From these experiments, it evidently consists of vapour of iodine and hydrogen, which combine in equal volumes, without change of their primitive bulk. Hydriodic acid is partly decomposed at a red-heat, and the decomposition is complete if it be mixed with oxygen. Water is formed, and iodine separated.

We can easily obtain an aqueous hydriodic acid very economically, by passing sulphuretted hydrogen gas through a mixture of water and iodine in a Woolfe's bottle. On heating the liquid obtained, the excess of sulphur flies off, and leaves liquid hydriodic acid. At temperatures below 262°, it parts with its water; and becomes of a density=1.7. At 262° the acid distils over. When exposed to the air, it is speedily decomposed, and iodine is evolved. Concentrated sulphuric and nitric acids also decompose it. When poured into a saline solution of lead, it throws down a fine orange precipitate. With solution of peroxide of mercury, it gives a red precipitate; and with that of silver, a white precipitate insoluble in ammonia. Hydriodic acid may also be formed, by passing hydrogen over iodine at an elevated temperature.

The compounds of hydriodic acid with the salifiable bases may be easily formed, either by direct combination, or by acting on the basis, in water, with iodine. The latter mode is most economical. Upon a determinate quantity of iodine, pour solution of potassa or soda, till the liquid ceases to be coloured. Evaporate to dryness, and digest the dry salt in alkohol of the specific gravity 0.810, or 0.820. As the iodate is not soluble in this liquid, while the hydriodate is very soluble, the two salts easily separate from each other. After having washed the iodate two or three times with alkohol, dissolve it in water, and neutralize it with acetic acid. Evaporate to dryness, and digest the dry salt in alcohol, to remove the acetate. After two or three washings, the iodate is pure. As for the alkohol containing the hydriodate, distil it off, and then complete the neutralization of the potassa, by means of a little hydriodic acid separately obtained. Sulphurous and muriatic acids, as well as sulphuretted hydrogen, produce no change on the hydriodates, at the usual temperature of the air.

Chlorine, nitric acid, and concentrated sulphuric, instantly decompose them, and separate the iodine.

With solution of silver, they give a white precipitate insoluble in ammonia; with the pernitrate of mercury, a greenish-yellow precipitate; with corrosive sublimate, a precipitate of a fine orange-red, very soluble in an excess of hydriodate; and with nitrate of lead, a precipitate of an orange-yellow colour. They dissolve iodine, and acquire a deep reddish brown colour.

Hydriodate of potassa, or in the dry state, *iodide of potassium*, yields crystals like sea-salt, which melt and sublime at a red heat. This salt is not changed by being heated in contact with air. 100 parts of water at 64°, dissolve 143 of it. It consists of 15.5 iodine, and 5 potassium.

Hydriodate of soda, called in the dry state *iodide of sodium*, may be obtained in pretty large flat rhomboidal prisms. It consists, when dry, of 15.5 iodine+3 sodium.

Hydriodate of barytes crystallises in fine prisms, similar to muriate of strontites. In its dry state, it consists of 15.5 iodine +8.75 barium.

The *hydriodates of lime* and *strontites* are very soluble; and the first exceedingly deliquescent.

Hydriodate of ammonia results from the combination of equal volumes of ammoniacal and hydriodic gases; though it is usually prepared by saturating the liquid acid with ammonia. It is nearly as volatile as sal ammoniac; but it is more soluble and more deliquescent. It crystallises in cubes.

Hydriodate of magnesia is formed by uniting its constituents together; it is deliquescent, and crystallises with difficulty.—It is decomposed by a strong heat.

Hydriodate of zinc is easily obtained, by putting iodine into water with an excess of zinc, and favouring their action by heat. When dried it becomes an iodide.

All the hydriodates have the property of dissolving abundance of iodine: and thence they acquire a deep reddish-brown colour. They part with it on boiling, or when exposed to the air after being dried."

HYDRO-CHLORIC ACID. Muriatic acid; a compound of chlorine and hydrogen. See *Muriatic acid.*

HYDRO-CYANIC ACID. See *Prussic acid.*

HYDRO-FLUORIC ACID. *Acidum hydrofluoricum.* This is procured by distilling, in lead or silver, a mixture of one part of the purest fluor spar, in fine powder, with two of sulphuric acid. The heat required is not considerable; sulphate of lime remains in the retort, and a highly acrid and corrosive liquid passes over, which requires the assistance of ice for its condensation.

HYDRO-SULPHURIC ACID. The aqueous solution of sulphuretted hydrogen, is so called by Gay Lussac.

HYDRO-SULPHUROUS ACID. When three volumes of sulphuretted hydrogen gas and two of sulphurous acid gas, both dry, are mixed together over mercury, they are condensed into a solid orange yellow body, which Dr. Thompson calls hydro-sulphurous acid.

HYDRO'A. (From υδωρ, water.) A watery pustule.

HYDROCARBONATE. See *Carburetted hydrogen gas.*

HYDROCA'RDIA. (From υδωρ, water, and καρδια, the heart.) *Hydrocordis. Hydrops pericardii.* Dropsy of the heart. Dropsy of the pericardium. A collection of fluid in the pericardium, which may be either coagulable lymph, serum, or a puriform fluid. It produces symptoms similar to those of hydrothorax, with violent palpitation of the heart, and mostly an intermittent pulse. It is incurable.

HYDROCE'LE. (From υδωρ, water, and κηλη, a tumour.) The term *hydrocele*, used in a literal sense, means any tumour produced by water: but surgeons have always confined it to those which possess either the membranes of the scrotum, or the coats of the testicle and its vessels. The first of these, viz. that which has its seat in the membranes of the scrotum, anasarca integumentorum, is common to the whole bag, and to all the cellular substance which loosely envelopes both the testes. It is, strictly speaking, only a symptom of a disease, in which the whole habit is most frequently more or less concerned, and very seldom affects the part only. The latter, or that which occupies the coats immediately investing the testicle and its vessels, hydrocele tunicæ vaginalis, is absolutely local, very seldom affects the common membrane of the scrotum, generally attacks one side only; and is frequently found in persons who are perfectly free from all other complaints.

The anasarca integumentorum retains the impression of the finger. The vaginal hydrocele has an undulating feel.

The hydrocele of the tunica vaginalis testis is a morbid accumulation of the water separated on the internal surface of the tunica vaginalis, to moisten or lubricate the testicle.

From its first appearance, it seldom disappears or diminishes, but, generally continues to increase, sometimes rapidly, at others more slowly. In some it grows to a painful degree of distension in a few months: in others, it continues many years with little disturbance. As it enlarges, it becomes more tense, and is sometimes transparent; so that if a candle is held on the opposite side, a degree of light is perceived through the whole tumour; but the only certain distinction is the fluctuation, which is not found when the disease is a hernia of the omentum, or intestines, or an inflammatory or a scirrhous tumour of the testicle.

HYDROCELE CYSTATA. Encysted hydrocele of the spermatic cord resembles the common hydrocele; but the tumour does not extend to the testicle, which may be felt below or behind it, while, in the hydrocele of the vaginal coat, when large, the testicle cannot be discovered. In this disease also, the penis is not buried in the tumour. Sometimes the fluid is contained in two distinct cells; and this is discovered by little contractions in it. It is distinguished from the anasarcous hydrocele by a sensible fluctuation, and the want of the inelastic pitting; from hernia, by its beginning below, from its not receding in an horizontal position, and not enlarging by coughing and sneezing.

HYDROCELE FUNICULI SPERMATICI, or hydrocele of the spermatic cord. Anasarcous hydrocele of the spermatic cord sometimes accompanies ascites, and, at other times, it is found to be confined to the cellular substance, in or about the spermatic cord. The causes of this disease may be obstructions in the lymphatics, leading from the part, in consequence of scirrhous affections of the abdominal viscera, or the pressure of a truss applied for the cure of hernia.

When the affection is connected with anasarca in other parts, it is then so evident as to require no particular description. When it is local, it is attended with a colourless tumour in the course of the spermatic cord, soft and inelastic to the touch, and unaccompanied with fluctuation. In an erect position of the body it is of an oblong figure: but when the body is recumbent, it is flatter, and somewhat round. Generally it is no longer than the part of the cord which lies in the groin; though sometimes it extends as far as the testicle, and even stretches the scrotum to an uncommon size. By pressure a great part of the swelling can always be made to recede into the abdomen. It instantly, however, returns to its former situation, on the pressure being withdrawn.

HYDROCELE PERITONÆI. The common dropsy of the belly.

HYDROCELE SPINALIS. A watery swelling on the vertebræ.

HYDROCE'PHALUS. (From ὑδωρ, water, and κεφαλη, the head.) *Hydrocephalum; Hydrencephalus.* Dropsy of the brain. Dropsy of the head. A genus of disease arranged by Cullen, in the class *Cachexiæ*, and order *Intumescentiæ*. It is distinguished by authors into external and internal:

1. *Hydrocephalus externus*, is a collection of water between the membranes of the brain.

2. *Hydrocephalus internus*, is when a fluid is collected in the ventricles of the brain, producing dilatation of the pupils, apoplexy, &c. See *Apoplexia*. It is sometimes of a chronic nature, when the water has been known to increase to an enormous quantity, effecting a diastasis of the bones of the head, and an absorption of the brain.

Pain in the head, particularly across the brow, stupor, dilatation of the pupils, nausea, vomiting, preternatural slowness of the pulse, and convulsions, are the pathognomic symptoms of this disease, which have been laid down by the generality of writers.

Hydrocephalus is almost peculiar to children, being rarely known to extend beyond the age of twelve or fourteen; and it seems more frequently to arise in those of a scrophulous and ricketty habit than in others. It is an affection which has been observed to pervade families, affecting all or the greater part of the children at a certain period of their life; which seems to show that, in many cases, it depends more on the general habit, than on any local affection, or accidental cause.

The disease has generally been supposed to arise in consequence either of injuries done to the brain itself, by blows, falls, &c. from scirrhous tumours or excrescences within the skull, from original laxity or weakness in the brain, or from general debility and an impoverished state of the blood.

With respect to its proximate cause, very opposite opinions are still entertained by medical writers, which, in conjunction with the equivocal nature of its symptoms, prove a source of considerable embarrassment to the young practitioner. Some believe it to be inflammatory, and bleed largely.

Dr. Withering observes, that in a great many cases, if not in all, congestion, or slight inflammation, are the precursors to the aqueous accumulation.

Dr. Rush thinks that, instead of its being considered an idiopathic dropsy, it should be considered only as an effect of a primary inflammation or congestion of blood in the brain. It appears, says he, that the disease, in its first stage, is the effect of causes which produce a less degree of that inflammation which constitutes phrenitis; and that its second stage is a less degree of that effusion which produces serous apoplexy in adults. The former partakes of the nature of the chronic inflammation of Dr. Cullen, and the asthenic inflammation of Dr. Brown.—There are others again who view the subject in a very different light. Dr. Darwin supposes inactivity, or torpor of the absorbent vessels of the brain, to be the cause of hydrocephalus internus; but he confesses in another part of his work, that the torpor of the absorbent vessels may often exist as a secondary effect.

Dr. Whytt, who has published an ingenious treatise on the disease, observes, the immediate cause of every kind of dropsy is the same; viz. such a state of the parts as makes the exhalent arteries throw out a greater quantity of fluids than the absorbents can take up. From what he afterwards mentions, he evidently considers this state as consisting in debility.

As many cases are accompanied with an increased or inflammatory action of the vessels of the brain, and others again are observed to prevail along with general anasarca, it seems rational to allow that hydrocephalus is, in some instances, the consequence of congestion, or slight inflammation in the brain; and that, in others, it arises either from general debility or topical laxity. In admitting these as incontrovertible facts, Dr. Thomas is, at the same time, induced to suppose that the cases of it occurring from mere debility are by no means frequent.

The great analogy subsisting between the symptoms which are characteristic of inflammation, and those which form the first stage of the acute species of hydrocephalus, (for the disease, as already observed, has been divided into the chronic and acute by some writers,) together with the good effects often consequent on blood-letting, and the inflammatory appearance which the blood frequently exhibits, seem to point out strong proof of the disease being, in most instances, an active inflammation, and that it rarely occurs from mere debility, as a primary cause.

The progress of the disorder has, by some, been divided into three stages.

When it is accompanied by an increased or inflammatory action of the brain, as not uncommonly happens, its first stage is marked with many of the symptoms of pyrexia, such as languor, inactivity, loss of appetite, nausea, vomiting, parched tongue, hot, dry skin, flushing of the face, headache, throbbing of the temporal arteries, and quickened pulse; which symptoms always suffer an exacerbation in the evening, but towards morning become milder.

When it is unaccompanied by any inflammatory action of the brain, many of these appearances are not to be observed. In these cases, it is marked by a dejection of countenance, loss of appetite, pains over the eyes, soreness of the integuments of the cranium to the touch, propensity to the bed, aversion to being moved, nausea, and costiveness. The disease, at length, makes a remarkable transition, which denotes the commencement of its second stage. The child screams out, without being able to assign any cause; its sleep is much disturbed; there is a considerable dilatation of the pupils of the eyes, without any contraction on their being exposed to light; lethargic torpor, with strabismus, or perhaps double vision ensues, and the pulse becomes slow and unequal.

In the third stage, the pulse returns again to the febrile state, becoming uncommonly quick and variable; and coma, with convulsions, ensue. When the accumulation of water is very great, and the child young, the sutures recede a considerable way from each other, and the head, towards the end, becomes much enlarged.

When recoveries have actually taken place in hydrocephalus, we ought probably to attribute more to the efforts of nature than to the interference of art. It is always to be regarded as of difficult cure.

An accumulation of water in the ventricles of the brain, is one of the most common appearances to be observed on dissection. In different cases, this is accumulated in greater or less quantities. It sometimes amounts only to a few ounces, and occasionally to some pints. When the quantity of water is considerable, the fornix is raised at its anterior extremity, in consequence of its accumulation, and an immediate opening of communication is thereby formed between the lateral ventricles. The water is of a purer colour and more limpid than what is found in the dropsy of the thorax, or abdomen. It appears, however, to be generally of the same nature with the water that is accumulated in these cavities. In some instances, the water in hydrocephalus, contains a very small proportion of coagulable matter, and in others it is entirely free from it.

When the water is accumulated to a very large quantity in the ventricles, the substance of the brain appears to be a sort of pulpy bag, containing a fluid. The skull, upon such occasions, is very much enlarged in size, and altered in its shape; and it appears exceedingly large in proportion to the face. On removing the scalp, the bones are found to be very thin, and there are frequently broad spots of membrane in the bone. These appearances are, however, only to be observed where the disease has been of some years' continuance.

In some cases, where the quantity of water collected is not great, the substance of the brain has appeared to be indurated, and in others softened. At times, the organ has been found gorged with blood; collections also of a viscid tenacious matter have been discovered in cysts, upon its external surface, and tumours have been found attached to its substance.

The treatment must be prompt and active to give a tolerable chance of success. The general indications are, in the first stage, to lessen the inflammatory action, afterwards to promote absorption. Should the patient be about the age of puberty, of a plethoric habit, and the symptoms run high at the beginning, it will be proper to take some blood, especially from the temporal artery, or the jugular vein; but, if younger, or the disease more advanced, a sufficient quantity may be withdrawn by leeches, applied to the temples, or in the direction of the sutures The bowels must then be thoroughly evacuated by some active cathartic, as they are usually very torpid, calomel with scammony, or jalap, for example; and, in the progress of the complaint, this function must be kept up with some degree of activity. For this purpose, calomel may be given in divided doses, or some other mercurial preparation, which may not run off too rapidly, producing mere watery stools, but regularly clear out the bowels, as well as the liver, and promote the other secretions. Besides, mercury is the most powerful remedy in rousing the absorbents, and some of the most remarkable cures of this disease, even at an advanced period, have been effected by it; whence it would be advisable, where the disease was proceeding rapidly, and particularly if the bowels were irritable, to use mercurial frictions, that the system might be sooner affected. Another very important step, after clearing the bowels, is to apply some evaporating lotion assiduously to the scalp, previously shaved; and the antiphlogistic regimen should be steadily observed. Diaphoretics will generally be proper, assisted by the warm bath; and diuretics, on some occasions, may be useful; but digitalis, which has been recommended on this ground, seems more likely to avail by lessening arterial action. Blisters may be applied to the temples, behind the ears, or to the nape of the neck, each perhaps successively: and dressed with savine cerate occasionally, to increase the discharge, and irritation externally: issues appear not so likely to prove beneficial. Errhines may farther contribute to obviate internal effusion. Electricity has been proposed to rouse the absorbents in the second stage; but its efficacy, and even propriety, is very doubtful. Should the progress of the complaint be fortunately arrested, the strength must be established by a nutritious diet, and tonic medicines; taking care to keep the bowels in good order, and the head cool: an issue, under these circumstances, may be a very useful remedy.

HYDROCEPHALUS ACUTUS. See *Hydrocephalus.*

HYDROCEPHALUS EXTERNUS. Water between the brain and its membranes.

HYDROCEPHALUS INTERNUS. Water in the ventricles of the brain.

HYDROCO'TYLE. (From υδωρ, water, and κοτυλη, the cotula.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Digynia.*

2. The name, in some pharmacopœias, for the common marsh or water cotula, or penny-wort, which is said to possess acrid qualities.

HYDROCY'STIS. (From υδωρ, water, and κυστις, a vesicle.) An encysted dropsy.

HY'DROGEN. (*Hydrogenium;* from υδωρ, water, and γινομαι, to become, or γενναω, to produce, because with oxygen it produces water.) Base of *inflammable air.*

Hydrogen is a substance not perceptible to our sensations in a separate state; but its existence is not at all the less certain. Though we cannot exhibit it experimentally uncombined, we can pursue it while it passes out of one combination into another; we cannot, indeed, arrest it on its passage, but we never fail to discover it, at least if we use the proper chemical means, when it presents itself to our notice in a new compound.

Hydrogen, as its name expresses, is one of the constituent elements of water, from which it can alone be procured. Its existence was unknown till lately. It is plentifully distributed in nature, and acts a very considerable part in the processes of the animal and vegetable economy. It is one of the ingredients in the varieties of bitumen, oils, fat, ardent spirit, æther, and, in fact, all the proximate, component parts of animal and vegetable bodies. It forms a constituent part of all animal and vegetable acids. It is one of the constituents of ammonia and of various other compound gases.

It possesses so great an affinity for caloric, that it can only exist separately in the state of gas; it is consequently impossible to procure it in the concrete or liquid state, independent of combination.

Solid hydrogen, therefore, united to caloric and light, forms HYDROGEN GAS.

Properties of Hydrogen Gas.

This gas, which was formerly called inflammable air, was discovered by Cavendish, in the year 1768, or rather he first obtained it in a state of purity, and ascertained its more important properties, though it had been noticed long before. The famous philosophical candle attests the antiquity of this discovery.

Hydrogen gas, like oxygen gas, is a triple compound, consisting of the ponderable base of hydrogen, caloric, and light. It possesses all the mechanical properties of atmospheric air. It is the lightest substance whose weight we are able to estimate: when in its purest state, and free from moisture, it is about fourteen times lighter than atmospheric air. It is not fitted for respiration; animals when obliged to breathe in it, die almost instantaneously. It is decomposed by living vegetables, and its basis becomes one of the constituents of oil, resin, &c. It is inflammable, and burns rapidly when kindled, *in contact with atmospheric air or oxygen gas*, by means of the electric spark, or by an inflamed body; and burns, when pure, with a yellowish lambent flame: but all burning substances are immediately extinguished when immersed in it. It is, therefore, incapable of supporting combustion. It is not injurious to growing vegetables. It is unabsorbable by most substances: water absorbs it very sparingly. It is capable of dissolving carbon, sulphur, phosphorus, arsenic, and many other bodies. When its basis combines with that of oxygen gas, water is formed; with nitrogen it forms ammonia. It does not act on earthy substances.

Method of obtaining Hydrogen Gas.—A ready method of obtaining hydrogen gas consists in subjecting water to the action of a substance which is capable of decomposing this fluid.

1. For this purpose, let sulphuric acid, previously diluted with four or five times its weight of water, be poured on iron filings, or bits of zinc, in a small retort, or gas-bottle, called a pneumatic flask, or proof; as soon as the diluted acid comes in contact with the metal, a violent effervescence takes place, and hydrogen gas escapes without external heat being applied. It may be collected in the usual manner over water, taking care to let a certain portion escape on account of the atmospheric air contained in the disengaging vessels.

The production of hydrogen gas in the above way is owing to the decomposition of water. The iron, or zinc, when in contact with this fluid, in conjunction with sulphuric acid, has a greater affinity to oxygen than the hydrogen has; the oxygen, therefore, unites to it, and forms an oxide of that metal which is instantly attacked and dissolved by the acid; the other constituent part of the water, the hydrogen, is set free, which, by uniting with caloric, assumes the form of hydrogen gas. The oxygen is, therefore, the bond of union between the metal and the acid.

The hissing noise, or effervescence, observable during the process, is owing to the rapid motion excited in the mixture by means of the great number of air-bubbles quickly disengaged and breaking at the surface of the fluid.

We see, also, in this case, that *two* substances exert an attraction, and are even capable of decomposing jointly a *third*, which neither of them is able to do singly; *viz.* if we present sulphuric acid alone, or iron or zinc alone, to water, they cannot detach the oxygen from the hydrogen of that fluid; but, if both are applied, a decomposition is instantly effected. This experiment, therefore, proves that the agency of chemical affinity between two or more bodies may lie dormant, until it is called into action by the interposition of another body, which frequently exerts no energy upon any of them in a separate state. Instances of this kind were formerly called *predisposing affinities.*

2. Iron, in a red heat, has also the property of decomposing water, by dislodging the oxygen from its combination with hydrogen, in the following manner:—

Let a gun-barrel, having its touch-hole screwed up, pass through a furnace, or large crucible perforated for that purpose, taking care to incline the barrel at the narrowest part; adjust to its upper extremity a retort charged with water, and let the other extremity terminate in a tube introduced under a receiver in the pneumatic trough. When the apparatus is thus disposed, and well luted, bring the gun-barrel to a red heat, and, when thoroughly red-hot, make the water in the retort boil; the vapour, when passing through the red-hot tube, will yield hydrogen gas abundantly. In this experiment, the oxygen of the water combines with the iron at a red heat, so as to convert it into an oxide, and the caloric applied combines with the hydrogen of the water, and forms hydrogen gas. It is, therefore, the result of a double affinity, that of the oxygen of the water for the metal, and that of its hydrogen for caloric.

The more caloric is employed in the experiment of decomposing water by means of iron, &c. the sooner is the water decomposed.

Hydrogen gas combined with carbon, is frequently found in great abundance in mines and coal-pits, where it is sometimes generated suddenly, and becomes mixed with the atmospheric air of these subterraneous cavities. If a lighted candle be brought in, this mixture often explodes, and produces the most dreadful effects. It is called, by miners, *fire damp*. It generally forms a cloud in the upper part of the mine, on account of its levity, but does not mix there with atmospheric air, unless some agitation takes place. The miners frequently set fire to it with a candle, lying at the same time flat on their faces to escape the violence of the shock. An easier and more safe method of clearing the mine, is by leading a long tube through the shaft of it, to the ash-pit of a furnace; by this means the gas will be conducted to feed the fire.

Sir Humphrey Davy has invented a valuable instrument, called a *safety lamp*, which will enable the miners to convey a light into such impure air without risk. This is founded on the important discovery, made by him, that flame is incapable of passing through minute apertures in a metallic substance, which yet are pervious to air: the reason of which appears to be, that the ignited gas, or vapour, is so much cooled by the metal in its passage, as to cease being luminous.

Hydrogen gas, in whatever manner produced, *always* originates from water, either in consequence of a preceding decomposition, by which it had been combined in the state of solid or fixed hydrogen, with one of the substances employed, or from a decomposition of water actually taking place during the experiment.

There are instances recorded of a vapour issuing from the stomach of dead persons, which took fire on the approach of a candle. We even find accounts, in several works, of the combustion of living human beings, which appeared to be spontaneous. Dr. Swediaur has related some instances of porters at Warsaw, who having drank abundantly of spirit, fell down in the street, with the smoke issuing out of their mouths; and people came to their assistance, saying they would take fire; to prevent which, they made them drink a great quantity of milk, or used a more singular expedient, by causing them to swallow the urine of the bystanders, immediately on its evacuation.

However difficult it may be to give credit to such narratives, it is equally difficult to reject them entirely, without refusing to admit the numerous testimonies of men, who were, for the most part, worthy of credit. *Citizen Lair* has collected all the circumstances of this nature which he found dispersed in different books, and has rejected those which did not appear to be supported by respectable testimony, to which he has added some others related by persons still living. These narratives are nine in number; they were communicated to the Philomathic Society, at Paris, and inserted in the bulletin, Thermidor, An. 5, No. 29. The cause of this phenomenon has been attributed to a development of hydrogen gas taking place in the stomachs of these individuals.

Lair believes that the bodies of these people were not burned perfectly spontaneously, but it appeared to be owing to some very slight external cause, such as the fire of a candle, taper, or pipe.

Hydrogen gas, seleniuretted. This gas is colourless. It reddens litmus. Its density has not been determined by experiment. Its smell resembles, at first, that of sulphuretted hydrogen gas; but the sensation soon changes, and another succeeds, which is at once pungent, astringent, and painful. The eyes become almost instantly red and inflamed, and the sense of smelling entirely disappears. A bubble of the size of a little pea is sufficient to produce these effects. Of all the bodies derived from the inorganic kingdom, seleniuretted hydrogen is that which exercises the strongest action on the animal economy. Water dissolves this gas; but in what proportions is not known. This solution disturbs almost all the metallic solutions, producing black or brown precipitates, which assume, on rubbing with polished hæmatites, a metallic lustre. Zinc, manganese, and cerium, form exceptions. They yield flesh-coloured precipitates, which appear to be hydro-seleniurets of the oxides, whilst the others, for the most part, are merely metallic seleniurets.

Hydrogen, sulphuretted. Sulphuretted hydrogen gas possesses the properties of an acid; for when absorbed by water, its solution reddens vegetable blues; it combines also with alkalies, earths, and with several metallic oxides. Sulphuretted hydrogen combined with any base, forms a *hydro-sulphuret*, which may be also called a *hepatule*, to distinguish it from an *hepar*, which is the union of sulphur singly with a base. Sulphuretted hydrogen gas possesses an extremely offensive odour, resembling that of putrid eggs. It kills animals, and extinguishes burning bodies. When in contact with oxygen gas, or atmospheric air, it is inflammable. Mingled with nitrous gas, it burns with a yellowish green flame. It is decomposed by ammonia, by oxy-muriatic acid gas, and by sulphurous acid gas. It has a strong action on the greater number of metallic oxides. Its specific gravity is about 1.18 when pure. It is composed, according to Thomson, of sixteen parts of sulphur, and one of hydrogen. It has the property of dissolving a small quantity of phosphorus.

Sulphuretted hydrogen gas may be obtained in several ways:—

1. Take dry sulphuret of potassa, put it into a tubulated retort, lodged in a sand-bath, or supported over a lamp; direct the neck of the retort under a receiver placed in the pneumatic trough; then pour gradually upon the sulphuret diluted sulphuric, or muriatic acid; a violent effervescence will take place, and sulphuretted hydrogen gas will be liberated. When no more gas is produced spontaneously, urge the mixture with heat, by degrees, till it boils, and gas will again be liberated abundantly.

The water made use of for receiving it, should be heated to about 80° or 90°; at this temperature it dissolves little of the gas: whereas, if cold water be made use of, a much greater quantity of it is absorbed.

Explanation.—Though sulphur makes no alteration on water, which proves that sulphur has less attraction for oxygen than hydrogen has, yet if sulphur be united to an alkali, this combination decomposes water whenever it comes in contact with it, though the alkali itself has no attraction either for oxygen or hydrogen.

The formation of this gas explains this truth. On adding the sulphuret of potassa to the water, this fluid becomes decomposed, part of the sulphur robs it of its oxygen; and forms with it sulphuric acid; this generated acid unites to part of the alkali, and forms sulphate of potassa. The liberated hydrogen dissolves another part of the sulphur, and forms with it sulphuretted hydrogen, the basis of this gas, which is retained by the separated portion of the alkali. The sulphuric or muriatic acid added now extricates it from the alkali, and makes it fly off in the form of gas.

Diluted muriatic acid seems best adapted for the production of sulphuretted hydrogen gas from alkaline sulphurets. If nitric acid be made use of it must be much diluted. Sulphuric acid yields little gas, unless assisted by heat. When the proportion of sulphur in the sulphuret exceeds that of the alkali, the dense sulphuric acid poured upon it emits sulphurous acid gas. All the rest of the acids may be made use of for decomposing the sulphurets.

2. When iron and sulphur are united together, they afford a large quantity of sulphuretted hydrogen gas, on submitting them to the action of heat, in contact with diluted muriatic acid.

Melt together, in a crucible, equal parts of iron filings and sulphur; the product is a black brittle mass, called sulphuret of iron. Reduce this to powder, and put it, with a little water, into a tubulated retort; add diluted muriatic acid, and apply a gentle heat, till no more gas is disengaged. The philosophy of this experiment is analogous to the former. Part of the oxygen of the water unites to part of the sulphur, and forms sulphuric acid; another part oxydizes the iron, which, dissolved by the acid, forms sulphate of iron: the hydrogen of the water unites to another part of the sulphur, and forms sulphuretted hydrogen, which becomes gaseous by the addition of caloric.

3. Sulphuretted hydrogen gas may also be obtained by heating an alkaline sulphuret, with the addition of water, without the aid of an acid. In this case, the water is also decomposed; its hydrogen unites with part of the sulphur, and forms sulphuretted hydrogen; the oxygen of the water unites with another part of the sulphur, and produces sulphuric acid, which joins to the alkali and forms a sulphate. The sulphuretted hydrogen becomes disengaged by heat in the gaseous form.

4. Sulphuretted hydrogen gas may be obtained by passing hydrogen gas through sulphur, in a state of fusion.

For this purpose, put sulphur into a gun-barrel, or Wedgwood's tube, and place it across a furnace; fit to the lower extremity a bent glass tube, which goes under a receiver placed in the pneumatic trough, and adapt to the upper extremity a tubulated retort, or other apparatus proper for producing hydrogen gas. The sulphur must then be heated, and, when melted, the hydrogen gas evolved must be made to pass over it, which, in this manner, will dissolve part of the sulphur, and become converted into sulphuretted hydrogen gas.

5. It may likewise be procured in the following direct manner: let a small quantity of sulphur be enclosed in a jar full of hydrogen gas, and melt it by means of a burning-glass. This method does not succeed except the hydrogen gas be as dry as possible, for its affinity to sulphur is weakened in proportion to its moisture.

6. The method, however, which affords it purest, is by treating sulphuret of antimony with diluted muriatic acid. The explanation is similar to the preceding processes.

Hydrogen, carburetted. See *Carburetted hydrogen gas.*

Hydrogen, percarburetted. See *Carburetted hydrogen gas.*

Hydrogen, subcarburetted. See *Carburetted hydrogen gas.*

Hydrogen, phosphuretted. See *Phosphorus.*

Hydrogen, subphosphuretted. See *Phosphorus.*

Hydrogen gaz, heavy, carbonated. See *Carbonated hydrogen gas.*

Hydrogen gaz, light, carbonated. See *Carburetted hydrogen gas.*

HYDROGURET. See *Uret.*

Hydroguret of carbon. See *Carburetted hydrogen gas.*

HYDROLA′PATHUM. (From υδωρ, water, and λαπαθον, the dock.) See *Rumex hydrolapathum.*

HYDRO′MELI. (From υδωρ, water, and μελι, honey.) *Mulsum; Aqua Mulsa; Melicratum; Braggat; Hydromel.* Water impregnated with honey. After it is fermented, it is called vinous hydromel, or mead.

HYDROTHIONIC ACID. See *Sulphuretted hydrogen.*

HYDROMETER. (*Hydrometer;* from υδωρ, water or fluid, and μετρον, a measure.) The best method of weighing equal quantities of corrosive volatile fluids, to determine their specific gravities, appears to consist in enclosing them in a bottle with a conical stopper, in the side of which stopper a fine mark is cut with a file. The fluid being poured into the bottle, it is easy to put in the stopper, because the redundant fluid escapes through the notch, or mark, and may be carefully wiped off. Equal bulks of water and other fluids are by this means weighed to a great degree of accuracy, care being taken to keep the temperature as equal as possible, by avoiding any contact of the bottle with the hand, or otherwise. The bottle itself shows with much precision, by a rise or fall of the liquid in the notch of the stopper, whether any such change have taken place.

The hydrometer of Fahrenheit consists of a hollow ball, with a counterpoise below, and a very slender stem above, terminating in a small dish. The middle, or half length of the stem, is distinguished by a fine line across. In this instrument every division of the stem is rejected, and it is immersed in all experiments to the middle of the stem, by placing proper weights in the little dish above. Then, as the part immersed is constantly of the same magnitude, and the whole weight of the hydrometer is known, this last weight added to the weights in the dish, will be equal to the weight of fluid displaced by the instrument, as all writers on hydrostatics prove. And accordingly, the sp. gravities for the common form of the tables will be had by the proportion:

As the whole weight of the hydrometer and
its load, when adjusted in distilled water,
Is to the number 1000, &c.
So is the whole weight when adjusted in any
other fluid
To the number expressing its specific gravity.

The hydrometers, or *pese-liqueurs*, of Baumé, though in reality comparable with each other, are subject in part to the defect, that their results, having no independent numerical measure, require explanation to those who do not know the instruments.

HYDROME′TRA. (From υδωρ, water, and μητρα, the womb.) *Hydrops uteri.* Dropsy of the womb. A genus of disease in the class *Cachexiæ*, and order *Intumescentiæ*, of Cullen. It produces a swelling of the hypogastric region, slowly and gradually increasing, resembling the figure of the uterus, yielding to, or fluctuating on pressure; without ischury or pregnancy. Sauvages enumerates seven species. It must be considered as a very rare disease, and one that can with difficulty be ascertained.

HYDRO′MPHALUM. (From υδωρ, water, and ομφαλος, the navel.) A tumour of the navel containing water.

HYDRO′NOSOS. (From υδωρ, water, and νοσος, a disease.) The sweating-sickness. See *Ephidrosis.*

HYDRO-OXIDE. See *Hydrate.*

HYDROPEDE′SIS. (From υδωρ, water, and πηδαω, to break out.) A breaking out into a violent sweat.

HYDROPHANE. *Oculus mundi.* A variety of opal, which has the property of becoming transparent on immersion in water.

HYDROPHO′BIA. (From υδωρ, water, and φοβεω, to fear.) *Rabies canina; Cynanthropia; Cynolesia.* Canine madness. This disease arises in consequence of the bite of a rabid animal, as a dog or cat, and sometimes spontaneously. It is termed hydrophobia, because persons that are thus bitten dread the sight or the falling of water when first seized. Cullen has arranged it under the class *Neuroses*, and order *Spasmi*, and defines it a loathing and great dread of drinking any liquids, from their creating a painful convulsion of the pharynx, occasioned most commonly by the bite of a mad animal.

There are two species of hydrophobia.

1. *Hydrophobia rabiosa*, when there is a desire of biting.

2. *Hydrophobia simplex*, when there is not a desire of biting.

Dr. James observes, that this peculiar affection properly belongs to the canine genus, viz. dogs, foxes, and wolves; in which animals only it seems to be innate and natural, scarcely ever appearing in any others, except when communicated from these. When a dog is affected with madness, he becomes dull, solitary, and endeavours to hide himself, seldom barking, but making a murmuring noise, and refusing all kinds of meat and drink. He flies at strangers; but in this stage, he remembers and respects his master: his head and tail hang down; he walks as if overpowered by sleep; and a bite, at this period, though dangerous, is not so apt to bring on the disease in the animal bitten as one inflicted at a later period. The dog at length begins to pant; he breathes quickly and heavily; his tongue hangs out; his mouth is continually open, and discharges a large quantity of froth. Sometimes he walks slowly, as if half asleep, and then runs suddenly, but not always directly forward. At last he forgets his master; his eyes have a dull, watery, red appearance; he grows thin and weak, often falls down, gets up, and attempts to fly at every thing, becoming very soon quite furious. The animal seldom lives in this latter state longer than thirty hours; and it is said that his bites towards the end of his existence, are the most dangerous. The throat of a person suffering hydrophobia is always much affected; and, it is asserted, the nearer the bite to this part the more perilous.

Hydrophobia may be communicated to the human subject from the bites of cats, cows, and other animals, not of the canine species, to which the affection has been previously communicated. However, it is from the bites of those domestic ones, the dog and cat, that most cases of hydrophobia originate. It does not appear that the bite of a person affected can communicate the disease to another; at least the records of medicine furnish no proof of this circumstance.

In the human species, the general symptoms attendant upon the bite of a mad dog, or other rabid animal, are, at some indefinite period, and occasionally long after the bitten part seems quite well; a slight pain begins to be felt in it, now and then attended with itching, but generally resembling a rheumatic pain. Then come on wandering pains, with an uneasiness and heaviness, disturbed sleep, and frightful dreams, accompanied with great restlessness, sudden startings, and spasms, sighing, anxiety, and a love for solitude. These symptoms continuing to increase daily, pains begin to shoot from the place which was wounded, all along up to the throat with a straitness and sensation of choking, and a horror and dread at the sight of water, and other liquids, together with a loss of appetite and tremor. The person is, however, capable of swallowing any solid substance with tolerable ease; but the moment that any thing in a fluid form is brought in contact with his lips, it occasions him to start back with much dread and horror, although he labours perhaps under great thirst at the time.

A vomiting of bilious matter soon comes on, in the course of the disease, and an intense hot fever ensues, attended with continual watching, great thirst, dryness and roughness of the tongue, hoarseness of the voice, and the discharge of a viscid saliva from the mouth, which the patient is constantly spitting out; together with spasms of the genital and urinary organs, in consequence of which the evacuations are forcibly thrown out. His respiration is laborious and uneasy, but his judgment is unaffected; and, as long as he retains the power of speech, his answers are distinct.

In some few instances, a severe delirium arises, and closes the tragic scene; but it more frequently happens, that the pulse becomes tremulous and irregular, that convulsions arise, and that nature being at length exhausted, sinks under the pressure of misery.

The appearances to be observed, on dissection in hydrophobia, are unusual aridity of the viscera and other parts; marks of inflammation in the fauces, gula, and larynx; inflammatory appearances in the stomach, and an accumulation or effusion of blood in the lungs. Some marks of inflammation are likewise to be observed in the brain, consisting in a serous effusion on its surface, or in a redness of the pia mater; which appearances have also presented themselves in the dog.

In some cases of dissection, not the least morbid appearance has been observed, either in the fauces, diaphragm, stomach, or intestines. The poison has, therefore, been conceived by some physicians to act upon the nervous system, and to be so wholly confined to it, as to make it a matter of doubt whether the qualities of the blood are altered or not. There is no known cure for this terrible disease: and the only preventive to be relied upon is the complete excision of the bitten part, which should be performed as soon as possible; though it may perhaps not be too late any time before the symptoms appear.

HYDROPHOSPHOROUS ACID. See *Phosphorous acid.*

HYDROPHTHA'LMIA. (From υδώρ, water, and οφθαλμος, the eye.) *Hydrophthalmium.* There are two diseases, different in their nature and consequence, thus termed. The one is a mere anasarcous or œdematous swelling of the eyelid. The other, the true hydrophthalmia, is a swelling of the bulb of the eye, from too great a collection of vitreous or aqueous humours.

HYDROPHTHA'LMIUM. (From υδωρ, water, and οφθαλμος, the eye.) See *Hydrophthalmia.*

HYDROPHTORIC ACID. *Acidum hydrophtoricum.* (From υδωρ, water, and φθοριος, destructive.) Ampére's name for the base of the fluoric acid, called by Davy *fluorine.* See *Hydro-fluoric acid.*

HYDROPHYSOCE'LE. (From υδωρ, water, φυση, flatulence, and κηλη, a tumour.) A swelling formed of water and air. It was applied to a hernia, in the sac of which was a fluid and air.

HYDRO'PICA. (From υδρωψ, the dropsy.) Medicines which relieve or cure dropsy.

HYDRO'PIPER. (From υδωρ, water, and πεπερι, pepper: so called from its biting the tongue like pepper, and growing in marshy places.) See *Polygonum hydropiper.*

HYDROPNEUMOSA'RCA. (From υδωρ, water, πνευμα, wind, and σαρξ, flesh.) A tumour of air, water, and solid substances.

HYDROPOI'DES. (From υδρωψ, a dropsy, and ειδος, likeness.) Serous or watery, formerly applied to liquid and watery excrements.

HY'DROPS. (*Hydrops, pis.* m.; from υδωρ, water.) Dropsy. A preternatural collection of serous or watery fluid in the cellular substance, or different cavities of the body. It receives different appellations, according to the particular situation of the fluid.

When it is diffused through the cellular membrane, either generally or partially, it is called *anasarca.* When it is deposited in the cavity of the cranium, it is called *hydrocephalus;* when in the chest, *hydrothorax,* or *hydrops pectoris;* when in the abdomen, *ascites.* In the uterus, *hydrometra,* and within the scrotum, *hydrocele.*

The causes of these diseases are a family disposition thereto, frequent salivations, excessive and long-continued evacuations, a free use of spirituous liquors, (which never fail to destroy the digestive powers,) scirrhosities of the liver, spleen, pancreas, mesentery, and other abdominal viscera; preceding diseases, as the jaundice, diarrhœa, dysentery, phthisis, asthma, gout, intermittents of long duration, scarlet fever, and some of the exanthemata; a suppression of accustomed evacuations, the sudden striking in of eruptive humours, ossification of the valves of the heart, polypi in the right ventricle, aneurism in the arteries, tumours making a considerable pressure on the neighbouring parts, permanent obstruction in the lungs, rupture of the thoracic duct, exposure for a length of time to a moist atmosphere, laxity of the exhalants, defect in the absorbents, topical weakness, and general debility.

HYDROPS ARTICULI. A white swelling of a joint is sometimes so called.

HYDROPS CYSTICUS. A dropsy enclosed in a bag, or cyst.

HYDROPS GENU. An accumulation of synovia, or serum, within the capsular ligament of the knee.

HYDROPS AD MATULAM. Diabetes.

HYDROPS MEDULLÆ SPINALIS. See *Hydrorachitis* and *Spina bifida.*

HYDROPS OVARII. A dropsy of the ovarium. See *Ascites.*

HYDROPS PECTORIS. See *Hydrothorax.*

HYDROPS PERICARDII. See *Hydrocardia.*

HYDROPS PULMONUM. Water in the cellular interstices of the lungs.

Hydrops scroti. See *Hydrocele.*

Hydrops uteri. See *Hydrometra.*

Hydropy'retus. (From υδωρ, water, and πυρετος, fever.) A sweating fever.

HYDRORACHI'TIS. (From υδωρ, water, and ραχις, the spine.) A fluctuating tumour, mostly situated on the lumbar vertebræ of new-born children. It is a genus of disease in the class *Cachexiæ*, and order *Intumescentiæ*, of Cullen, and is always incurable. See *Spina bifida.*

Hydroro'satum. A drink made of water, honey, and the juice of roses.

HYDROSA'CCHARUM. (From ὑδωρ, water, and σακχαρον, sugar.) A drink made of sugar and water.

HYDROSA'RCA. (From ὑδωρ, water, and σαρξ, the flesh.) See *Anasarca.*

HYDROSARCOCE'LE. (From ὑδωρ, water, σαρξ, the flesh, and κηλη, a tumour.) Sarcocele, with an effusion of water into the cellular membrane.

HYDROSELENIC ACID. The best process which we can employ for procuring this acid, consists in treating the seleniuret of iron with the liquid muriatic acid. The acid gas evolved must be collected over mercury. As in this case a little of another gas, condensible neither by water nor alkaline solutions, appears, the best substance for obtaining absolutely pure hydroselenic acid would be seleniuret of potassium.

HYDROSELI'NUM. (From ὑδωρ, water, and σελινον, purslane.) A species of purslane growing in marshy places.

HYDROSULPHURET. *Hydrosulphuretum.* A compound of sulphuretted hydrogen with a salifiable basis.

Hydrosulphure'tum stibii luteum. See *Antimonii sulphuretum præcipitatum.*

Hydrosulphuretum stibii rubrum. *Kermes mineralis.* A hydro-sulphuret of antimony formerly in high estimation as an expectorant, sudorific, and antispasmodic, in difficult respiration, rheumatism, diseases of the skin and glands.

HYDROTHIONIC ACID. Some German chemists distinguish sulphuretted hydrogen by this name on account of its properties resembling those of an acid.

HYDROTHO'RAX. (From υδωρ, water, and θωραξ, the chest.) *Hydropsthoracis; Hydrops pectoris.* Dropsy of the chest. A genus of disease in the class *Cachexiæ*, and order *Intumescentiæ*, of Cullen. Difficulty of breathing, particularly when in an horizontal posture; sudden startings from sleep, with anxiety, and palpitations of the heart; cough, paleness of the visage, anasarcous swellings of the lower extremities, thirst, and a scarcity of urine, are the characteristic symptoms of hydrothorax; but the one which is more decisive than all the rest, is a fluctuation of water being perceived in the chest, either by the patient himself or his medical attendant, on certain motions of the body.

The causes which give rise to the disease, are pretty much the same with those which are productive of the other species of dropsy. In some cases, it exists without any other kind of dropsical affection being present; but it prevails very often as a part of more universal dropsy.

It frequently takes place to a considerable degree before it becomes very perceptible; and its presence is not readily known, the symptoms, like those of hydrocephalus, not being always very distinct. In some instances, the water is collected in both sacs of the pleura; but at other times, it is only in one. Sometimes it is lodged in the pericardium alone; but, for the most part, it only appears there when, at the same time, a collection is present in one or both cavities of the thorax. Sometimes the water is effused in the cellular texture of the lungs, without any being deposited in the cavity of the thorax. In a few cases, the water that is collected is enveloped in small cysts, of a membraneous nature, known by the name of hydatides, which seem to float in the cavity; but more frequently they are connected with, and attached to, particular parts of the internal surface of the pleura.

Hydrothorax often comes on with a sense of uneasiness at the lower end of the sternum, accompanied by a difficulty of breathing which is much increased by any exertion, and which is always most considerable during night, when the body is in an horizontal posture. Along with these symptoms there is a cough, that is at first dry, but which, after a time, is attended with an expectoration of thin mucus. There is likewise a paleness of the complexion, and an anasarcous swelling of the feet and legs, together with a considerable degree of thirst and a diminished flow of urine. Under these appearances, we have just grounds to suspect that there is a collection of water in the chest; but if the fluctuation can be perceived, there can then remain no doubt as to the reality of its presence.

During the progress of the disease, it is no uncommon thing for the patient to feel a numbness, or degree of palsy, in one or both arms, and to be more than ordinarily sensible to cold. With regard to the pulse, it is usually quick at first, but, towards the end, becomes irregular and intermitting.

Our prognostic in hydrothorax must, in general, be unfavourable, as it has seldom been cured, and, in many cases, will hardly admit even of alleviation, the difficulty of breathing continuing to increase, until the action of the lungs is at last entirely impeded by the quantity of water deposited in the chest. In some cases, the event is suddenly fatal; but, in others, it is preceded, for a few days previous to death, by a spitting of blood.

Dissections of this disease show that, in some cases, the water is either collected in one side of the thorax, or that there are hydatides formed in some particular part of it; but they more frequently discover water in both sides of the chest, accompanied by a collection in the cellular texture and principal cavities of the body. The fluid is usually of a yellowish colour; possesses properties similar to serum, and, with respect to its quantity, varies very much, being from a few ounces to several quarts. According to the quantity, so are the lungs compressed by it; and, where it is very considerable, they are usually found much reduced in size. When universal anasarca has preceded the collection in the chest, it is no uncommon occurrence to find some of the abdominal viscera in a scirrhous state.

The treatment of this disease must be conducted on the same general plan as that of anasarca. Emetics, however, are hazardous, and purgatives do not afford so much benefit; but the bowels must be kept regular, and other evacuating remedies may be employed in conjunction with tonics. Squill has been chiefly resorted to, as being expectorant as well as diuretic; but its power is usually not great, unless it be carried so far as to cause nausea, which cannot usually be borne to any extent. Digitalis is more to be relied upon: but it will be better to conjoin them, adding, perhaps, some form of mercury; and employing at the same time other diuretics, as the supertartrate or acetate of potassa, juniper berries, &c. Where febrile symptoms attend, diaphoretics will probably be especially serviceable, as the pulvis ipecacuanhæ compositus, or antimonials, in small doses; which last may also promote expectoration. Blisters to the chest will be proper in many cases, particularly should there be any pain or other mark of inflammatory action. Myrrh seems to answer better than most other tonics, as more decidedly promoting expectoration; or the nitric acid may be given, increasing the secretion of urine, as well as supporting the strength. The inhalation of oxygen gas is stated to have been in some instances singularly beneficial. Where the fluid is collected in either of the sacs of the pleura, the operation of paracentesis of the thorax may afford relief under urgent symptoms, and, perhaps, contribute to the recovery of the patient.

HYDROXURE. See *Hydrate.*

HYDRURET. A compound of hydrogen with a metal. See *Uret.*

HYGEIA. *Hygieia.* The goddess of health. One of the four daughters of Esculapius. She often accompanies her father in the monuments of him now remaining, and appears like a young woman, commonly holding a serpent in one hand, and a patera in the other. Sometimes the serpent drinks out of the patera; sometimes he twines about the whole body of the goddess.

HYGIE'NE. (From υγιαινω, to be well.) *Hygiesis.* Modern physicians have applied this term to that division of *therapeia* which treats of the diet and non-naturals of the sick.

HYGIE'SIS. See *Hygiene.*

HY'GRA. (From υγρος, humid.) An ancient term for liquid plasters.

HYGREMPLA'STRUM. (From υγρος, moist, and εμπλαςρον, a plaster.) A liquid plaster.

HYGROBLEPHA'RICUS. (From υγρος, humid, and βλεφαρον, the eye-lid.) Applied to the emunctory ducts in the extreme edge, or inner part, of the eye-lid.

HYGROCIRSOCE'LE. (From υγρος, moist, κιρσος, a varix, and κηλη, a tumour.) Dilated spermatic veins, or circocele, with dropsy of the scrotum.

HYGROCOLLY'RIUM. (From υγρος, liquid, and κολλυριον, a collyrium.) A collyrium composed of liquids.

HYGRO'LOGY. (*Hygrologia*; from υγρος, a humour or fluid, and λογος, a discourse.) The doctrine of the fluids.

HYGRO'MA. (Υγρωμα; from γρος, a liquid.) An encysted tumour, the contents of which are either serum or a fluid-like lymph. It sometimes happens that these tumours are filled with hydatids. Hygromatous tumours require the removal of the cyst, or the destruction of its secreting surface.

HYGRO'METER. (*Hygrometrum*; from υγρος, moist, and μετρον, a measure.) Hydrometer. An instrument to measure the degrees of moisture in the atmosphere. It also means an infirm part of the body, affected by moisture of the atmosphere.

HYGROMY'RUM. (From υγρος, moist, and μυρον, a liquid ointment.) A liquid ointment.

HYGROSCO'PIC. Substances which have the property of absorbing moisture from the atmosphere. See *Atmosphere.*

HYGROPHO'BIA. See *Hydrophobia.*

HY'LE. (Ὑλη, matter.) The materia medica, or matter of any kind that comes under the cognisance of a medical person.

HY'MEN. (From *Hymen,* the god of marriage, because this membrane is supposed to be entire before marriage, or copulation.) The hymen is a thin membrane, of a semilunar or circular form, placed at the entrance of the vagina, which it partly closes. It has a very different appearance in different women, but it is generally, if not always found, in virgins, and is very properly esteemed the test of virginity, being ruptured in the first act of coition. The remnants of the hymen are called the carunculæ myrtiformes. The hymen is also peculiar to the human species. There are two circumstances relating to the hymen which require medical assistance. It is sometimes of such a strong ligamentous texture, that it cannot be ruptured, and prevents the connection between the sexes. It is also sometimes imperforated, wholly closing the entrance into the vagina, and preventing any discharge from the uterus: but both these cases are extremely rare. If the hymen be of an unnaturally firm texture, but perforated, though perhaps with a very small opening, the inconveniences thence arising will not be discovered before the time of marriage, when they may be removed by a crucial incision made through it, taking care not to injure the adjoining parts.

The imperforation of the hymen will produce its inconveniences when the person begins to menstruate. For the menstruous fluid, being secreted from the uterus at each period, and not evacuated, the patient suffers much pain from the distension of the parts, many strange symptoms and appearances are occasioned, and suspicions injurious to her reputation are often entertained. In a case of this kind, for which Dr. Denman was consulted, the young woman, who was twenty-two years of age, having many uterine complaints, with the abdomen enlarged, was suspected to be pregnant, though she persevered in asserting the contrary, and had never menstruated. When she was prevailed upon to submit to an examination, the circumscribed tumour of the uterus was found to reach as high as the navel, and the external parts were stretched by a round soft substance at the entrance of the vagina, in such a manner as to resemble that appearance which they have when the head of a child is passing through them; but there was no entrance into the vagina. On the following morning an incision was carefully made through the hymen, which had a fleshy appearance, and was thickened in proportion to its detension. Not less than four pounds of blood, of the colour and consistence of tar, were discharged; and the tumefaction of the abdomen was immediately removed. Several stellated incisions were afterwards made through the divided edges, which is a very necessary part of the operation: and care was taken to prevent a re-union of the hymen till the next period of menstruation, after which she suffered no inconvenience. The blood discharged was not putrid or coagulated, and seemed to have undergone no other change after its secretion, but what was occasioned by the absorption of its more fluid parts. Some caution is required when the hymen is closed in those who are in advanced age, unless the membrane be distended by the confined menses; as Dr. Denman once saw an instance of inflammation of the peritonæum being immediately produced after the operaton, of which the patient died as in the true puerperal fever; and no other reason could be assigned for the disease.

The carunculæ myrtiformes, by their elongation and enlargement, sometimes become very painful and troublesome.

HYMENÆA. (From *Hymen,* the God of marriage; because, as Linnæus informs us, its younger leaves cohere together in pairs, throughout the night.) The name of a genus of plants. Class, *Decandria*; Order, *Monogynia.*

HYMENÆA COURBARIL. The systematic name

of the locust-tree which affords the resin called *gum anime*, which is now fallen into disuse, and is only to be found in the collections of the curious.

HYMENIUM. (From *υμην*, a membrane.) The dilated exposed membrane of gymnocarpous mushrooms, in which the seed is placed. See *Gymnocarpi.*

HYMENODES. (From *υμην*, a membrane, and *ειδος*, likeness.) An old term for such urine as is found to be full of little films and pellicles. Hippocrates applies it also to the menstrual discharges when mixed with a tough viscid phlegm.

HYO. Names compounded of this word belong to muscles which originate from, or are inserted into, or connected with the os hyoides; as, *Hyo-glossus*, *Hyo-pharyngeus*, *Genio-hyoglossus*, *&c.*

HYO-GLOSSUS. *Cerato-glossus* of Douglas and Cowper. *Basio-cerato-chondro-glossus* of Albinus. *Hyo-chondro-glosse* of Dumas. A muscle situated at the sides between the os hyoides and the tongue. It arises from the basis, but chiefly from the corner of the os hyoides, running laterally and forwards to the tongue, which it pulls inwards and downwards.

HYOI′DES OS. (From the Greek letter *υ*, and *ειδος*, likeness: so named from its resemblance.) This bone, which is situated between the root of the tongue and the larynx, derives its name from its supposed resemblance to the Greek letter *υ*, and is, by some writers, described along with the parts contained in the mouth. Ruysch has seen the ligaments of the bone so completely ossified, that the os hyoides was joined to the temporal bones by anchylosis. In describing this bone, it may be distinguished into its body, horns, and appendices. The body is the middle and broadest part of the bone, so placed that it may be easily felt with the finger in the fore-part of the throat. Its fore-part, which is placed towards the tongue, is irregularly convex, and its inner surface, which is turned towards the larynx, is unequally concave. The *cornua*, or horns, which are flat, and a little bent, are considerably longer than the body of the bone, and may be said to form the sides of the *υ*. These horns are thickest near the body of the bone. At the extremity of each is observed a round tubercle, from which a ligament passes to the thyroid cartilage. The appendices, or lesser horns, *cornua minora*, as they are called by some writers, are two small processes, which in their size and shape are somewhat like a grain of wheat. They rise up from the articulations of the cornua, with the body of the bone, and are sometimes connected with the styloid process on each side, by means of a ligament. It is not unusual to find small portions of bone in these ligaments; and Ruysch, as we have already observed, has seen them completely ossified In the fœtus, almost the whole of the bone is in a cartilaginous state, excepting a small point of a bone in the middle of its body, and in each of its horns. The appendices do not begin to appear till after birth, and usually remain cartilaginous many years. The os hyoides serves to support the tongue, and affords attachment to a variety of muscles, some of which perform the motions of the tongue, while others act on the larynx and fauces.

HYOPHARYNGE′US. (From *υοειδες*, the hyoid bone, and *φαρυγξ*, the pharynx.) A muscle so called from its origin in the os hyoides, and its insertion in the pharynx.

HYOPHTHA′LMUS. (From *υς*, a swine, and *οφθαλμος*, an eye: so named from the supposed resemblance of its flower to a hog's-eye.) Hog's-eye plant. Most probably the *Buphthalmum spinosum* of Linnæus.

HYOSCIANIA. A new vegetable alkali extracted by Dr. Brande from henbane. See *Hyoscyamus niger.*

HYOSCY′AMUS. (From *υς*, a swine, and *κυαμος*, a bean: so named because hogs eat it as a medicine, or it may be because the plant is hairy and bristly, like a swine.)

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia.*

2. The pharmacopœial name of the henbane. See *Hyoscyamus niger.*

HYOSCYAMUS ALBUS. This plant, a native of the South of Europe, possesses similar virtues to the hyoscyamus niger.

HYOSCYAMUS LUTEUS. A species of tobacco, the *Nicotiana rustica* of Linnæus.

HYOSCYAMUS NIGER. The systematic name of common, or black henbane, called also *Faba suilla; Apollinaris altercum; Agone; Altercangenon; Hyoscyamus—foliis amplexicaulibus sinuatis, floribus sessilibus* of Linnæus. The leaves of this plant, when recent, have a slightly fœtid smell, and a mucilaginous taste; when dried, they lose both taste and smell, and part also of their narcotic power. The root possesses the same qualities as the leaves, and even in a more eminent degree. Henbane resembles opium in its action, more than any other narcotic dose. In a moderate dose, it increases at first the strength of the pulse, and occasions some sense of heat, which are followed by diminished sensibility and motion; in some cases, by thirst, sickness, stupor, and dimness of vision. In a larger quantity it occasions profound sleep, hard pulse, and sometimes fierce delirium, ending in coma, or convulsions, with a remarkable dilatation of the pupil, distortion of the countenance, a weak tremulous pulse and eruption of petechiæ. On dissection gangrenous spots have been found on the internal surface of the stomach. Its baneful effects are best counteracted by a powerful emetic, and by drinking largely of the vegetable acids.

Henbane has been used in various spasmodic and painful diseases, as in epilepsy, hysteria, palpitation, headache; paralysis, mania, and scirrhus. It is given in the form of the inspissated juice of the fresh leaves, the dose of which is from one to two grains; which requires to be gradually increased. It is sometimes employed as a substitute for opium, where the latter, from idiosyncrasy, occasions any disagreeable symptom. The henbane also is free from the constipating quality of the opium.

Dr. Brande has extracted a new alkali from this plant, which he calls *hyosciania.* It crystallises in long prisms, and when neutralised by sulphuric or nitric acid, forms characteristic salts.

HYOTHYROI′DES. (From *υοειδες*, the hyoid bone, and *θυροειδης*, the thyroid cartilage.) A muscle named from its origin in the hyoid bone, and insertion in the thyroid cartilage.

HYPA′CTICA. (From *υπαγω*, to subdue.) Medicines which evacuate the fæces.

HYPALEI′PTRUM. (From *υπαλειφω*, to spread upon.) A spatula for spreading ointments with.

HYPE′LATA. (From *υπελαω*, to move.) Medicines which purge.

HYPERÆTHE′SIS. (From *υπερ*, and *αισθανομαι*, to feel.) Error of appetite, whether by excess or deficiency.

HYPERCATHA′RSIS. (From *υπερ*, *supra*,

over or above, and καθαιρω, to purge.) *Hyperinesis; Hyperinos.* An excessive purging from medicines.

HYPERCORYPHO′SIS. (From υπερ, above, and κορυφη, the vertex.) A prominence or protuberance. Hippocrates calls the lobes of the liver and lungs *Hypercoryphoses.*

HYPE′RCRISIS. (Ὑπερκρισις; from υπερ, over or above, and κρινω, to separate.) A critical excretion above measure; as when a fever terminates in a looseness, the humours may flow off faster than the strength can bear, and therefore it is to be checked.

HYPERE′MESIS. (From υπερ, in excess, and εμεω, to vomit.) An excessive evacuation by vomiting.

HYPEREPHIDRO′SIS. (From υπερ, excess, and ιδρως, sweat.) Immoderate sweating.

HYPE′RICUM. (From υπερ, over, and εικων, an image or spectre: so named because it was thought to have power over and to drive away evil spirits.) 1. The name of a genus of plants in the Linnæan system. Class, *Polyadelphia;* Order, *Polyandria.* St. John's wort.

2. The pharmacopœial name of the common St. John's wort. See *Hypericum perfoliatum.*

HYPERICUM BACCIFERUM. *Caa-opia; Arbuncula gummifera Braziliensis.* A juice exudes from the wounded bark of this plant, in the Brazils, which in a dry state resembles camboge, but is rather darker.

HYPERICUM CORIS. *Coris lutea; Coris legitima cretica.* Bastard St. John's wort. The seeds are diuretic, emmenagogue, and antispasmodic.

HYPERICUM PERFOLIATUM. The systematic name of the St. John's wort called also *fuga dæmonum;* and *androsæmum. Hypericum perforatum—floribus trigynis, caule ancipiti, foliis obtusis pellucido-punctatis,* of Linnæus. This indigenous plant was greatly esteemed by the ancients, internally in a great variety of diseases, and externally as an anodyne and discutient, but is now very rarely used. The flowers were formerly used in our pharmacopœia, on account of the great proportion of resinous oily matter, in which the medical efficacy of the plant is supposed to reside, but are now omitted.

HYPERICUM SAXATILE. *Hypericoides.* The seeds are said to be diuretic and antispasmodic.

HYPERI′NA. (From υπερ, in excess, and ινεω, to evacuate.) Medicines which purge excessively.

HYPERINE′SIS. See *Hypercatharsis.*

HYPERI′NOS. See *Hypercatharsis.*

HYPERO′A. (From υπερ, above, and ωον, the top of a house.) The palate.

HYPEROPHARYNGE′US. (From υπερ, above, and φαρυγξ, the pharynx.) A muscle named from its situation above the pharynx.

HYPEROSTO′SIS. (From υπερ, upon, and ωον, a bone.) See *Exostosis.*

HYPERO′UM. (From υπερ, above, and ωον, the roof, or palate.) A foramen in the upper part of the palate.

Hyperoxymuriate of potassa. See *Murias potassæ oxygenatus.*

Hyperoxymuriatic acid. See *Chlorine.*

HYPEROXYMURIATE. A salt now called a chlorate.

HYPERSARCO′MA. (From υπερ, in excess, and σαρξ, flesh.) *Hypersarcosis.* A fleshy excressence. A polypus.

HYPERSARCO′SIS. See *Hypersarcoma.*

HYPERSTENE. Labradore schiller spar. Found in Labradore, Greenland, and Isle of Skye. It has a beautiful copper colour when cut and polished into rings, brooches, &c.

HYPERYDRO′SIS. (From υπερ, in excess, and υδωρ, water.) A great distension of any part, from water collected in it.

HYPE′XODOS. (From υπο, under, and εξοδος, passing out.) A flux of the belly.

HYPNO′BATES. (From υπνος, sleep, and βαινω, to go.) *Hypnobatasis.* One who walks in his sleep. See *Oneirodynia.*

HYPNOLO′GIA. (From υπνος, sleep, and λογος, a discourse.) A dissertation, or directions for the due regulation of sleeping and waking.

HYPNOPOIE′TICA. (From υπνος, sleep, and ποιεω, to cause.) Medicines which procure sleep. See *Anodyne.*

HYPNO′TIC. (*Hipnoticus;* from υπνος, sleep.) See *Anodyne.*

HYPO-SULPHITE. A sulphuretted sulphite.

HYPOÆ′MA. (From υπο, under, and αιμα, blood; because the blood is under the cornea.) An effusion of red blood into the chambers of the eye.

HYPOCARO′DES. (From υπο, and καρος, a carus.) *Hypocarothis.* One who labours under a low degree of carus.

HYPOCATHA′RSIS. (From υπω, under, and καθαιρω, to purge.) It is when a medicine does not work so much as expected, or but very little. Or a slight purging, when it is a disorder.

HYPOCAU′STRUM. (From υπο, under, and καιω, to burn.) A stove, hot-house, or any such like contrivance, to preserve plants from cold air.

HYPOCERCHNA′LEON. (From υπο, and κερχνος, an asperity of the fauces.) A stridulous kind of asperity of the fauces.

HYPOCHEO′MENOS. (From υπο, under, and χεω, to pour.) One who labours under a cataract.

HYPOCHLORO′SIS. (From υπο, and χλωρωσις, the green-sickness.) A slight degree of chlorosis.

HYPOCHO′NDRIAC. (From υπο, under, and χονδρος, a cartilage.) 1. Belonging to the hypochondria.

2. A person affected with lowness of spirits. See *Hypochondriasis.*

HYPOCHONDRIAC REGIONS. *Regiones hypochondriacæ; Hypochondria.* The spaces in the abdomen that are under the cartilages of the spurious ribs on each side of the epigastrium.

HYPOCHONDRI′ASIS. (From υποχονδριακος, one who is hipped.) *Hypochondriacus morbus; Affectio hypochondriaca; Passio hypochondriaca.* The hypochondriac affection, vapours, spleen, &c. A genus of disease in the class *Neuroses,* and order *Adynamiæ,* of Cullen, characterised by dyspepsia, languor, and want of energy; sadness and fear, from uncertain causes, with a melancholic temperament.

The state of mind peculiar to hypochondriacs is thus described by Cullen:—"A languor, listlessness, or want of resolution and activity, with respect to all undertakings; a disposition to seriousness, sadness and timidity, as to all future events, and apprehension of the worst or most unhappy state of them; and, therefore, often upon slight grounds, and apprehension of great evil. Such persons are particularly attentive to the state of their own health, to every the smallest change of feeling in their bodies; and from any unusual sensation, perhaps of the slightest kind, they apprehend great danger, and even death itself. In respect to these feelings and fears, there is commonly the most obstinate belief and persuasion." He adds, that it is only when the state of mind just described is joined with indigestion, in either sex, somewhat in years, of a melancholic temperament, and a firm and rigid habit, that the disease takes the name of *Hypochondriacism.*

The seat of the hypochondriac passion is in the stomach and bowels; for first these parts are disordered, then the others suffer from the connexion. The causes are, sorrow, fear, or excesses of any of the passions; too long continued watching; irregular diet. Those habitually disposed to it, (and these causes have little effect in other constitutions, have generally a sallow or brown complexion, and a down-cast look; a rigidity of the solids, and torpor of the nervous system. Whatever may occasion nervous disorders in general, may also be the cause of this.

The signs of this complaint are so various, that to describe them is to describe almost every other disease; but, in general, there is an insurmountable indolence, dejected spirits, dread of death, costiveness, a slow and somewhat difficult inspiration, flatulencies in the prima viæ, and various spasmodic affections. It is seldom fatal; but if neglected, or improperly treated, may bring on incurable melancholy, jaundice, madness, or vertigo, palsy, and apoplexy.

On dissections of hypochondriacal persons, some of the abdominal viscera, (particularly the liver and spleen,) are usually found considerably enlarged. In some few instances, effusion and a turgescence of the vessels have been observed in the brain.

This being a disease of a mixed description, the treatment must be partly corporeal, partly mental; but it has been too often neglected, as merely imaginary and their complaints met by argument or raillery, which, however, can only weaken their confidence in the practitioner. It may be very proper to inform them, that their disorder is not so dangerous as they suppose, and may be removed by suitable remedies; but to tell them they ail nothing, is absurd. In reality, medicine is often of much service; and though others have been cured chiefly by amusements, country air, and exercise, it by no means follows, that their disorder was only in the imagination. In so far as dyspeptic symptoms appear, these must be encountered by the remedies pointed out under that head; antacids, aperients, &c. Sometimes emetics, or drastic cathartics, have produced speedy relief; but they are too debilitating to be often employed. The bowels will be better regulated by milder remedies, as castor oil, senna, aloes, (unless they are subject to hæmorrhoids,) and the like; and magnesia may at the same time correct acidity; but if the liver be torpid, some mercurial preparation will be of more avail. Flatulence and spasmodic pains may be relieved by aromatics, ether, the fœtid gum resins, musk, valærian, &c. but severe and obstinate pain, or high irritation, will be best attacked by opium: it is important, however, to guard against the patient getting into the habitual use of this remedy. Occasionally mild tonics appear useful, especially chalybeate waters; and tepid bathing, with friction, gentle exercise, and warm clothing, are important to keep up the function of the skin. The diet should be light, and sufficiently nutritious; but moderation must be enjoined to those who have been accustomed to indulge too much in the luxuries of the table; and, in all cases, those articles which are ascescent, flatulent, or difficult of digestion, must be avoided. Malt liquors do not usually agree so well as wine or spirits, considerably diluted; but these stimuli should never be allowed unnecessarily. The mental treatment required will be such as is calculated to restore the strength, and correct the aberrations of the judgment. When any false association of ideas occurs, the best mode of removing it is, by keeping up a continued train of naturally associated impressions of superior force, which may amuse the mind, and moderately exercise, without exhausting it. A variety of literary recreations and diversions, especially in the open air, with agreeable company, will be therefore advisable; frequently changing the scene, taking them to watering places, and adopting other expedients, to prevent them from dwelling too much upon their own morbid feelings.

HYPOCHO′NDRIUM. (From υπο, under, and χονδρος, a cartilage.) That part of the body which lies under the cartilages of the spurious ribs.

HYPO′CHYMA. (From υπο, and χοω, to pour; because the ancients thought that the opacity proceeded from something running under the crystalline humour.) A cataract.

HYPOCI′STIS. (From υπο, under, and κιϛος, the cistus.) See *Asarum hypocistis* and *Cytinus hypocistis.*

HYPOCLE′PTCIUM. (From υπο, under, and κλεπτω, to steal.) A chemical vessel for separating liquors, particularly the essential oil of any vegetable from the water; and named because it steals, as it were, the water from the oil.

HYPOCOELON. (From υπο, under, and κοιλον, a cavity.) The cavity under the lower eye-lid.

HYPOCOPHO′SIS. A trifling degree of deafness.

HYPOCRA′NIUM. (From υπο, under, and κρανιον, the skull.) A kind of abscess, so called because seated under the cranium, between it and the dura mater.

HYPOCRATERIFORMIS. (From υπο, χρατηρ, a cup, goblet or salver, and *forma* likeness.) Hypocrateriform, salver-shaped: applied to leaves so shaped, as those of the *Primula.*

HYPODEI′RIS. In Rufus Ephesius, it is the extremity of the fore-part of the neck.

HYPODE′RMIS. (From υπο, under, and δερμα, the skin.) 1. The skin over the clitoris, which covers it like a prepuce.

2. The clitoris.

HYPO′DESIS. (From υπο, under, and δεω, to bind.) *Hypodesmus.* An underswathe, or bandage.

HYPO′GALA. (From υπο, under, and γαλα, milk; because it is a milk-like effusion, under the cornea.) A collection of white humour, like milk, in the chambers of the eye. There are two species of this disease; the one takes place, it is said, from a deposition of the milk, as is sometimes observed in women who suckle; the other from a depression of the milky cataract.

HYPOGA′STRIC. (From υπο, under, and γαϛηρ, the stomach.) Belonging to the hypogastria. See *Hypogastrium.*

HYPOGASTRIC ARTERIES. Of or belonging to the hypogastrium. See *Iliac arteries.*

HYPOGASTRIC REGION. See *Hypogastrium.*

HYPOGA′STRIUM. (From υπο, under, and γαϛηρ, the stomach.) *Regio hypogastrica.* The region of the abdomen that reaches from above the pubes to within three fingers' breadth of the navel.

HYPOGASTROCE′LE. (From υπογαϛριον, the hypogastrium, and κηλη, a tumour.) A hernia, in the hypogastric region.

HYPOGLO′SSIS. (From υπο, under, and

γλωσσα, the tongue.) The under part of the tongue, which adheres to the jaw.

HYPOGLO'SSUS. (From υπο, under, and γλωσσα, the tongue.) A nerve which goes to the under part of the tongue.

HYPOGLO'TTIDES. (From υπο, under, and γλωττα, the tongue.) They are a kind of lozenge to be held under the tongue until they are dissolved.

HYPOGLU'TIS. (From υπο, under, and γλουτος, the nates.) It is the fleshy part under the nates towards the thigh. Some say it is the flexure of the coxa, under the nates.

Hypo'mia. (From υπο, under, and ωμος, shoulder.) In Galen's Exegesis, it is the part subjacent to the shoulder.

HYPONITRIC ACID. See *Nitric acid.*

HYPONITROUS ACID. Pernitrous acid. "It appears, from the experiments of Gay Lussac, that there exists an acid, formed of 100 azote and 150 oxygen. When into a test tube filled with mercury, we pass up from 500 to 600 volumes of deutoxide of azote, a little alkaline water, and 100 parts of oxygen gas, we obtain an absorption of 500, proceeding from the condensation of the 100 parts of oxygen with 400 of deutoxide of azote. Now these 400 parts are composed of 200 azote and 200 oxygen; consequently the new acid is composed of azote and oxygen, in the ratio of 100 to 150, as we have said above. It is the same acid, according to Gay Lussac, which is produced on leaving for a long time a strong solution of potassa in contact with deutoxide of azote. At the end of three months he found that 100 parts of deutoxide of azote were reduced to 25 of protoxide of azote, and that crystals of *hyponitrite* (*pernitrite*) were formed.

Hyponitrous acid (called *pernitrous* by the French chemists) cannot be insulated. As soon as we lay hold, by an acid, of the potassa, with which it is associated, it is transformed into deutoxide of azote, which is disengaged, and into nitrous or nitric acid, which remains in solution."

Hypo'nomos. (From υπονομος, a phagedenic ulcer. 1. A subterraneous place.

2. A deep phagedenic ulcer.

Hypope'dium. (From υπο, under, and πους, the foot.) A cataplasm for the sole of the foot.

Hypo'phora. (From υποφερομαι, to be carried or conveyed underneath.) A deep fistulous ulcer.

HYPOPHOSPHOROUS ACID. This acid was lately discovered by Dulong. Pour water on the phosphuret of barytes, and wait till all the phosphuretted hydrogen be disengaged. Add cautiously to the filtered liquid dilute sulphuric acid, till the barytes be all precipitated in the state of sulphate. The supernatant liquid is hypophosphorous acid, which should be passed through a filter. This liquid may be concentrated by evaporation, till it become viscid. It has a very sour taste, reddens vegetable blues, and does not crystallise. It is probably composed of 2 primes of phosphorous=3+1 of oxygen. Dulong's analysis approaches to this proportion. He assigns, but from rather precarious *data*, 100 phosphorus to 37.44 oxygen. The hypophosphites have the remarkable property of being all soluble in water; while many of the phosphates and phosphites are insoluble.

HYPOPHTHA'LMION. (From υπο, under, and οφθαλμος, the eye.) The part under the eye which is subject to swell in a cachexy, or dropsy.

Hypo'physis. (From υπο, under, and φυω, to produce.) A disease of the eyelids, when the hairs grow so much as to irritate and offend the pupil.

HYPO'PYUM. (From υπο, under, and πυον, pus; because the pus is under the cornea.) *Hypopion; Pyosis; Abscessus oculi.* An accumulation of a glutinous yellow fluid, like pus, which takes place in the anterior chamber of the aqueous humour, and frequently also in the posterior one, in consequence of severe, acute ophthalmy, particularly the internal species. This viscid matter of the hypopyum, is commonly called pus; but Scarpa contends, that it is only coagulating lymph. The symptoms portending an extravasaton of caagulable lymph in the eye, or an hypopyum, are the same as those which occur in the highest stage of violent acute ophthalmy, viz. prodigious tumefaction of the eye-lids; the same swelling and redness as in chemosis: burning heat and pain in the eye; pains in the eyebrow, and nape of the neck; fever, restlessness, aversion, to the faintest light, and a contracted state of the pupil.

Hypori'nion. (From υπο, under, and ριν, the nose.) A name for the parts of the upper lip below the nostrils.

Hyposa'rca. (From υπο, under, and σαρξ, flesh.) *Hyposarcidios.* A collection of fluid or air in the cellular membrane.

Hypospadiæ'os. (From υπο, under, and σπαω, to draw.) The urethra terminating under the glans.

Hypospathi'smus. (From υπο, under, and σπαθη, a spatula.) The name of an operation formerly used in surgery, for removing defluxions in the eyes. It was thus named from the instrument with which it was performed.

Hyposphа'gma. (From υπο, under, and σφαζω, to kill.) *Aposphagma.* An extravasation of blood in the tunica adnata of the eye, from external injury.

Hyposple'nia. (From υπο, under, and σπλην, the spleen.) A tumour under the spleen.

Hyposta'phyle. (From υπο, and ςαφυλη, the uvula.) Relaxation of the uvula.

Hypo'stasis. (From υφιςημι, to subside.) A sediment, as that which is occasionally let down from urine.

HYPOSULPHUREOUS ACID. "In order to obtain hyposulphureous acid, Herschel mixed a dilute solution of hyposulphite of strontites with a slight excess of dilute sulphuric acid, and after agitation poured the mixture on three filters. The first was received into a solution of carbonate of potassa, from which it expelled carbonic acid gas. The second portion being received successively into nitrates of silver and mercury, precipitated the metals copiously in the state of sulphurets, but produced no effect on solutions of copper, iron, or zinc. The third, being tasted, was acid, astringent, and bitter. When fresh filtered, it was clear: but it became milky on standing, depositing sulphur, and colouring sulphureous acid. A moderate exposure to air, or a gentle heat, caused its entire decomposition."

HYPOSULPHURIC ACID. "Gay Lussac and Welther have recently announced the discovery of a new acid combination of sulphur and oxygen, intermediate between sulphureous and sulphuric acids, to which they have given the name of hyposulphuric acid. It is obtained by passing a current of sulphureous acid gas over the black oxide of manganese. A combination takes place; the excess of the oxide of manganese is separated by dissolving the hyposulphate of manganese in water. Caustic barytes precipitates the manganese, and forms with the new acid a very soluble salt, which, freed from excess of barytes by a current of carbonic acid, crystallises regularly, like the nitrate or muriate of barytes. Hyposulphate of barytes being thus obtained, sulphuric acid is cautiously added to the solution, which throws down the barytes, and leaves the hyposulphuric acid in the water. This acid bears considerable concentration under the receiver of the air pump. It consists of five parts of oxygen to four of sulphur. The greater number of the hyposulphates, both earthy and metallic, are soluble and crystallise; those of barytes and lime are unalterable in the air.

Hyposulphuric acid is distinguished by the following properties:—

1st, It is decomposed by heat into sulphurous and sulphuric acids.

2d, It forms soluble salts with barytes, strontites, lime, lead, and silver.

3d, The hyposulphates are all soluble.

4th, They yield sulphurous acid when their solutions are mixed with acids, only if the mixture becomes hot of itself, or be artificially heated.

5th, They disengage a great deal of sulphurous acid at a high temperature, and are converted into neutral sulphates."

HYPO'THENAR. (From υπο, under, and θεναρ, the palm of the hand.) 1. A muscle which runs on the inside of the hand.

2. That part of the hand which is opposite to the palm.

HYPO'THESIS. An opinion, or a system of general rules, founded partly on fact but principally on conjecture. A theory explains every fact, and every circumstance connected with it; an hypothesis explains only a certain number, leaving some unaccounted for and others in opposition to it.

HYPO'THETON. (From υπο, under, and τιθημι, to put.) A suppository, or medicine introduced into the rectum, to procure stools.

Hypo'xylon. (From υπο, and ξυλον, wood.) A species of *clavaria*, which grows under old wood.

Hypozo'ma. (From υπο, and ζωννυμι, to bind round.) The diaphragm.

Hypsiglo'ssus. From υψιλοειδες, the hyoid bone, and γλωσσα, the tongue.) A muscle named from its origin in the os hyoides, and its insertion in the tongue.

HYPSILOI'DES. 1. The *Os hyoides.*

2. The hyoglossus muscle.

Hyptia'smos. (From υπτιαζω, to lie with the face upwards.) A supine decubiture, or a nausea, with inclination to vomit.

Hypu'lus. (From υπο, under, and ουλη, a cicatrix.) An ulcer under a cicatrix.

HYSSOP. See *Hyssopus.*

Hyssop hedge. See *Gratiola.*

Hyssopi'tes. (From υσσωπος, hyssop.) Wine impregnated with hyssop.

HYSSO'PUS. (Υσσωπος; from *Azob*, Hebrew.) 1. The name of a genus of plants in the Linnæan system. Class, *Didynamia;* Order, *Gymnospermia.* Hyssop.

2. The pharmacopœial name of the common hyssop. See *Hyssopus officinalis.*

Hyssopus capitata. Wild thyme.

Hyssopus officinalis. The systematic name of the common hyssop. *Hyssopus—spicis secundis, foliis lanceolatis* of Linnæus. This exotic plant is esteemed as an aromatic and stimulant, but is chiefly employed as a pectoral, and has long been thought useful in humoral asthmas, coughs, and catarrhal affections; for this purpose, an infusion of the leaves, sweetened with honey, or sugar, is recommended to be drank as tea.

HY'STERA. (From υϛερος, behind: so called because it is placed behind the other parts.) The womb. See *Uterus.*

HYSTERA'LGIA. (From υϛερα, the womb, and αλγος, pain.) A pain in the womb.

HYSTE'RIA. (From υϛερα, the womb, from which the disease was supposed to arise.) *Passio hysterica.* Hysterics. Dr. Cullen places this disease in the class *Neuroses*, and order *Spasmi.* There are four species:

1. *Hysteria chlorotica*, from a retention of the menses.

2. *Hysteria à leucorrhœa*, from a fluor albus.

3. *Hysteria à menorrhagia*, from an immoderate flow of the menses.

4. *Hysteria libidinosa*, from sensual desires.

The complaint appears under such various shapes, imitates so many other diseases, and is attended with such a variety of symptoms, which denote the animal and vital functions to be considerably disordered, that it is difficult to give a just character or definition of it; and it is only by taking an assemblage of all its appearances that we can convey a proper idea of it to others. The disease attacks in paroxysms or fits. These are sometimes preceded by dejection of spirits, anxiety of mind, effusion of tears, difficulty of breathing, sickness at the stomach, and palpitations at the heart; but it more usually happens, that a pain is felt on the left side, about the flexure of the colon, with a sense of distension advancing upwards, till it gets into the stomach, and removing from thence into the throat, it occasions, by its pressure, a sensation as if a ball was lodged there, which by authors has been called *globus hystericus.* The disease having arrived at this height, the patient appears to be threatened with suffocation, becomes faint, and is affected with stupor and insensibility; whilst, at the same time, the trunk of the body is turned to and fro, the limbs are variously agitated; wild and irregular actions take place in alternate fits of laughter, crying, and screaming; incoherent expressions are uttered, a temporary delirium prevails, and a frothy saliva is discharged from the mouth. The spasms at length abating, a quantity of wind is evacuated upwards, with frequent sighing and sobbing, and the woman recovers the exercise of sense and motion without any recollection of what has taken place during the fit; feeling, however, a severe pain in her head, and a soreness over her whole body. In some cases, there is little or no convulsive motion, and the person lies seemingly in a state of profound sleep, without either sense or motion. Hiccup is a symptom which likewise attends, in some instances, on hysteria; and now and then it happens, that a fit of hysteria consists of this alone. In some cases of this nature, it has been known to continue for two or three days, during which, it frequently seems as if it would suffocate the patient, and proceeds, gradually weakening her, till it either goes off or else occasions death by suffocation: but this last is extremely rare. Besides hiccup, other slight spasmodic affections sometimes wholly form a fit of hysteria, which perhaps continue for a day or two, and then either go off of themselves, or are removed by the aid of medicine. In some cases, the patient is attacked with violent pains in the back, which extend from the spine to the sternum, and at length become fixed upon the region of the stomach, being evidently of a spasmodic nature, and often prevailing in so high a degree as to cause clammy sweats, a pale cadaverous took, coldness of the extremities, and a pulse hardly perceptible.

Hysteric affections occur more frequently in the single state of life than in the married; and usually between the age of puberty and that of thirty-five years; and they make their attack oftener about the period of menstruation than at any other.

They are readily excited in those who are subject to them, by passions of the mind, and by every considerable emotion, especially when brought on by surprise; hence, sudden joy, grief, fear, &c. are very apt to occasion them. They have also been known to arise from imitation and sympathy.

Women of a delicate habit, and whose nervous system is extremely sensible, are those who are most subject to hysteric affections; and the habit which predisposes to their attacks, is acquired by inactivity and a sedentary life, grief, anxiety of mind, a suppression or obstruction of the menstrual flux, excessive evacuations, and a constant use of a low diet, or of crude unwholesome food.

Hysteria differs from hypochondriasis in the following particulars, and, by paying attention to them, may always readily be distinguished from it:—Hysteria attacks the sanguine and plethoric; comes on soon after the age of puberty; makes its onset suddenly and violently, so as to deprive the patient of all sense and voluntary motion: is accompanied with the sensation of a ball rising upwards in the throat, so as to threaten suffocation; is attended usually with much spasmodic affection; is more apt to terminate in epilepsy than in any other disease; and, on dissection, its morbid appearances are confined principally to the uterus and ovaria.

The reverse happens in hypochondriasis. It attacks the melancholic; seldom occurs till after the age of thirty-five; comes on gradually; is a tedious disease, and difficult to cure; exerts its pernicious effects on the membraneous canal of the intestines, as well by spasms as wind; is more apt to terminate in melancholy, or a low fever, than in any other disease; and, on dissection, exhibits its morbid effects principally on the liver, spleen, and pancreas, which are often found in a diseased state.

Another very material difference might be pointed out betwixt these two diseases, which is, that hysteria is much relieved by advancing in age, whereas hypochondriasis usually becomes aggravated.

The two diseases have often been confounded together; but, from considering the foregoing circumstances, it appears that a proper line of distinction should be drawn between them.

The hysteric passion likewise differs from a syncope, as in this there is an entire cessation of the pulse, a contracted face, and a ghastly countenance; whereas, in the uterine disorder, there is often something of a colour, and the face is more expanded; there is likewise, a pulse, though languid; and this state may continue some days, which never happens in a syncope.

It also differs from apoplexy, in which the abolition of sense and voluntary motion is attended with a sort of snoring, great difficulty of breathing, and a quick pulse; which do not take place in hysteria.

It differs from epilepsy, in that this is supposed to arise in consequence of a distension of the vessels of the brain: whereas, in hysteria, the spasmodic and convulsive motions arise from a turgescence of blood in the uterus, or in other parts of the genital system.

However dreadful and alarming an hysteric fit may appear, still it is seldom accompanied with danger, and the disease never terminates fatally, unless it changes into epilepsy, or that the patient is in a very weak reduced state.

The indications in this disease are, 1. To lessen the violence of the fits. 2. To prevent their return by obviating the several causes. Where the attack is slight, it may be as well to leave it in a great measure to have its course. But where the paroxysm is severe, and the disease of no long standing, occurring in a young plethoric female, as is most frequent, and especially from suppression of the menses, a liberal abstraction of blood should be made, and will often afford speedy relief. If this step do not appear advisable, and the disorder be rather connected with the state of the primæ viæ, an emetic may check its progress, if the patient can be got to swallow during a remission of the convulsions. At other times the application of cold water to the skin more or less extensively; strong and disagreeable odours, as hartshorn, burnt feathers, &c.; rubbing the temples with æther; antispasmodics, particularly opium, by the mouth or in glyster: the pediluvium, &c. may be resorted to according to the state of the patient. During the intervals, we must endeavour to remove any observable predisposition; in the plethoric by a spare diet, exercise, and occasional purgatives; in those who are weakly, and rather deficient in blood, by proper nourishment, with chalybeates, or other tonic medicines. The state of the uterine function must be particularly attended to, as well as that of the primæ viæ; those cathartics are to be preferred which are not apt to occasion flatulence, nor particularly irritate the rectum, unless where the menses are interrupted, when the aloetic preparations may claim a preference; and the perspiration should be maintained by warm clothing, particularly to the feet, with the prudent use of the cold bath. The mind ought also to be occupied by agreeable and useful pursuits, and regular hours will tend materially to the restoration of the general health.

HYSTERIA'LGES. (From *υςερα*, the womb, and *αλγος*, pain.) 1. An epithet for any thing that excites pain in the uterus.

2. Hippocrates applies this word to vinegar.

3. The pains which resemble labour-pains, generally called *false pains.*

HYSTERI'TIS. (From *υςερα*, the womb.) *Metritis.* Inflammation of the womb. A genus of disease in the class *Pyrexiæ*, and order *Phlegmasiæ*, of Cullen; characterised by fever, heat, tension, tumour, and pain in the region of the womb; pain in the os uteri when touched, and vomiting.

In natural labours, as well as those of a laborious sort, many causes of injury to the uterus, and the peritonæum which covers it, will be applied. The long continued action of the uterus on the body of the child, and the great pressure made by its head on the soft parts, will further add to the chance of injury. Besides these, an improper application of instruments, or an officiousness of the midwife in hurrying the labour, may have contributed to the violence. To these causes may be added exposure to cold, by taking the woman too early out of bed after delivery, and thereby throwing the circulating fluids upon the internal parts, putting a stop to the secretion of milk, or occasioning a suppression of the lochia.

An inflammation of the womb is sometimes perfectly distinct, but is more frequently communicated to the peritonæum, Fallopian tubes, and ovaria; and having once begun, the natural functions of the organ become much disturbed, which greatly adds to the disease. It is oftener met with in women of a robust and plethoric habit than in those of lax fibres and a delicate constitution, particularly where they have indulged freely in food of a heating nature, and in the use of spirituous liquors. It never prevails as an epidemic, like puerperal fever, for which it has probably often been mistaken; and to this we may, with some reason, ascribe the difference in the mode of treatment which has taken place among physicians.

An inflammation of the uterus shows itself usually about the second or third day after delivery, with a painful sensation at the bottom of the belly, which gradually increases in violence, without any kind of intermission. On examining externally, the uterus appears much increased in size, is hard to the feel, and on making a pressure upon it, the patient experiences great soreness and pain. Soon afterwards there ensues an increase in heat over the whole of the body, with pains in the head and back, extending into the groins, rigors, considerable thirst, nausea, and vomiting. The tongue is white and dry, the secretion of milk is usually much interrupted, the lochia are greatly diminished, the urine is high-coloured and scanty; the body is costive, and the pulse hard, full, and frequent.

These are the symptoms which usually present themselves when the inflammation does not run very high, and is perfectly distinct; but when it is so extensive as to affect the peritonæum, those of irritation succeed, and soon destroy the patient.

Uterine inflammation is always attended with much danger, particularly where the symptoms run high, and the proper means for removing them have not been timely adopted. In such cases, it may terminate in suppuration, scirrhus, or gangrene.

Frequent rigors, succeeded by flushings of the face, quickness and weakness of the pulse, great depression of strength, delirium, and the sudden cessation of pain and soreness in the region of the abdomen, denote a fatal termination. On the contrary, the ensuing of a gentle diarrhœa, the lochial discharge returning in due quantity and quality, the secretion of milk recommencing, and the uterus becoming gradually softer and less tender to the touch, with an abatement of heat and thirst, prognosticate a favourable issue.

When shiverings attack the patient, after several days' continuance of the symptoms, but little relief can be afforded by medicine, the event being generally fatal. In this case, the woman emaciates and loses her strength, becomes hectic, and sinks under colliquative sweating, or purging.

Upon opening the bodies of women who have died of this disease, and where it existed in a simple state, little or no extravasated fluid is usually to be met with in the cavity of the abdomen. In some instances, the peritonæal surfaces have been discovered free from the disease; whilst in others, that portion which covers the uterus and posterior part of the bladder, has been found partially inflamed. The inflammation has been observed, in some cases, to extend to the ovaria and Fallopian tubes, which, when cut open, are often loaded with blood. The uterus itself usually appears of a firm substance, but is larger than in its natural state, and, when cut into, a quantity of pus is often found. Gangrene is seldom, if ever, to be met with.

HYSTEROCE'LE. (From υϛερα, the womb, and κηλή, a tumour.) An hernia of the womb. This is occasioned by violent muscular efforts, by blows on the abdomen at the time of gestation, and also by wounds and abscesses of the abdomen which permit the uterus to dilate the part. Ruysch relates the case of a woman, who, becoming pregnant after an ulcer had been healed in the lower part of the abdomen, the tumid uterus descended into a dilated sac of the peritonæum in that weakened part, till it hung, with the included fœtus, at her knees. Yet when her full time was come, the midwife reduced this wonderful hernia, and, in a natural way, she was safely delivered of a son.

Hy'steron. (From υϛερος, afterwards; so named because it comes immediately after the fœtus.) The placenta.

HYSTEROPHY'SA. (From υϛερα, the womb, and φυσα, flatus.) A swelling, or distension of the womb from a collection of air in its cavity.

HYSTERO'TOMY. (*Hysterotomia;* from υϛερα, the womb, and τεμνω, to cut.) See *Cæsarian operation.*

Hysterotomatocia. See *Cæsarian operation.*

HYSTEROPTO'SIS. (From υϛερα, the womb, and πιπτω, to fall.) A bearing down of the womb.

HYSTRICI'ASIS. (From υϛριξ, a hedgehog, or porcupine.) A disease of the hairs, in which they stand erect, like porcupine quills. An account of this rare disease is to be seen in the *Philosophical Transactions*, No. 424.

Hy'stricis lapis. See *Bezoar hystricis.*

HYSTRI'TIS. See *Hysteritis.*

I.

IATRALEI'PTES. (From ιατρος, a physician, and αλειφω, to anoint.) One who undertakes to cure distempers by external unction and friction: Galen makes mention of such in his time, particularly one Diotas; and Pliny informs us, that this practice was first introduced by Prodicus of Selymbria, who was a disciple of Æsculapius.

IATROCHY'MICUS. (From ιατρος, a physician, and χυμια, chemistry.) *Chymiater.* A chemical physician, who cures by means of chemical medicines.

IATROLI'PTICE. (From ιατρος, a physician, and αλειφω, to anoint.) The method of curing diseases by unction and friction

IATROPHY'SICUS. (From ιατρος, physician, and φυσις, nature.) An epithet bestowed on some writings which treat of physical subjects with relation to medicine.

IBE'RIS. (So named from Iberia, the place of its natural growth.) 1. The name of a genus of plants in the Linnæan system. Class, *Tetradynamia;* Order, *Siliculosa.*

2. The pharmacopœial name of the *Sciatica cresses.* See *Lepidium iberis.*

IBIRA'CE. See *Guaiacum.*

I'BIS. Iβις. A bird much like our kingsfisher, taken notice of by the Egyptians, because, when it was sick, it used to inject with its long bill the water of the Nile into its fundament, whence Langius, lib. ii. ep. ii. says they learned the use of clysters.

IBI'SCUS. (From ιβις, the stork, who was said to chew it and inject it as a clyster.) Marshmallow.

IBI'XUMA. (From ιβισκος, the mallow, and ιξος, glue: so named from its having a glutinous leaf, like the mallow.) *Saponaria arbor.* The soap-tree, probably the *Sapindus saponaria* of Linnæus.

ICE. *Glacies.* Water made solid by the application of cold. It is frequently applied by surgeons to resolve external inflammatory diseases, to stop hæmorrhages, and constringe relaxed parts.

Iceland spar. A calcareous spar.

I'CHOR. (Iχωρ.) A thin, aqueous, and acrid discharge.

I'CTHYA. (Iχθυα, a fish-hook; from ιχθυς, a fish.) 1. The skin of the *Squatina*, or monkfish.

2. The name of an instrument like a fish-hook, for extracting the fœtus.

ICHTHYASIS. See *Ichthyosis.*

ICHTHYOCO'LLA. (From ιχθυς, a fish, and κολλα, glue.) *Colla piscium.* Isinglass. Fish-glue. This substance is almost wholly gelatin; 100 grains of good dry isinglass containing rather more than 98 of matter soluble in water.

Isinglass is made from certain fish found in the Danube, and the rivers of Muscovy. Willoughby and others inform us, that it is made of the sound of the Beluga; and Neumann, that it is made of the Huso Germanorum, and other fish, which he has frequently seen sold in the public markets of Vienna. Jackson remarks, that the sounds of cod, properly prepared, afford this substance; and that the lakes of America abound with fish from which the very finest sort may be obtained.

Isinglass receives its different shapes in the following manner: the parts of which it is composed, particularly the sounds, are taken from the fish while sweet and fresh, slit open, washed from their slimy *sordes*, divested of a very thin membrane which envelopes the sound, and then exposed to stiffen a little in the air. In this state, they are formed into rolls about the thickness of a finger, and in length according to the intended size of the staple: a thin membrane is generally selected for the centre of the roll, round which the rest are folded alternately, and about half an inch of each extremity of the roll is turned inwards.

Isinglass is best made in the summer, as frost gives it a disagreeable colour, deprives it of weight, and impairs its gelatinous principles.

Isinglass boiled in milk forms a mild nutritious jelly, and is thus sometimes employed medicinally. This, when flavoured by the art of the cook, is the blanc-manger of our tables. A solution of isinglass in water, with a very small proportion of some balsam, spread on black silk, is the court-plaster of the shops.

ICHTHYOPHTHAL'MITE. Fish eye-stone. See *Apophyllite.*

ICHTHYO'SIS. (From ιχθυα, the scale of a fish; from the resemblance of the scales to those of a fish.) *Ichthyasis.* A genus of diseases of the second order of Dr. Willan's disease of the skin. The characteristic of ichthyosis is a permanently harsh, dry, scaly, and, in some cases, almost horny texture of the integuments of the body, unconnected with internal disorder. Psoriasis and Lepra differ from this affection, in being but partially diffused, and in having deciduous scales. The arrangement and distribution of the scales in ichthyosis are peculiar. Above and below the olecranon on the arm, says Dr. Willan, and in a similar situation with respect to the patella on the thigh and leg, they are small, rounded, prominent, or papillary, and of a black colour; some of the scaly papillæ have a short, narrow neck, and broad irregular tops. On some part of the extremities, and on the trunk of the body, the scales are flat and large, often placed like tiling, or in the same order as scales on the back of a fish; but, in a few cases, they have appeared separate, being intersected by whitish furrows. There is usually in this complaint a dryness and roughness of the soles of the feet; sometimes a thickened and brittle state of the skin in the palms of the hands, with large painful fissures, and on the face an appearance of the scurf rather than of scales. The inner part of the wrists, the hams, the inside of the elbow, the furrow along the spine, the inner and upper part of the thigh, are perhaps the only portions of the skin always exempt from the scaliness. Patients affected with ichthyosis are occasionally much harassed with inflamed pustules, or with large painful boils on different parts of the body; it is also remarkable, that they never seem to have the least perspiration or moisture of the skin. This disease did not, in any case, appear to Dr. Willan to have been transmitted hereditarily; nor was more than one child from the same parents affected with it. Dr. Willan never met with an instance of the horny rigidity of the integuments, *Ichthyosis cornea*, impeding the motion of the muscles or joints. It is, however, mentioned by authors as affecting the lips, prepuce, toes, fingers, &c. and sometimes as extending over nearly the whole body.

ICOSA'NDRIA. (From εκοσι, twenty, and ανηρ, a man, or husband.) The name of a class of plants in the sexual system of Linnæus, consisting of those which have hermaphrodite flowers furnished with twenty or more stamina that are inserted into the inner side of the calyx, or petals, or both. By this last circumstance is this class distinguished from *Polyandria.*

ICTERI'TIA. (From *icterus*, the jaundice.) 1. an eruption of yellowish spots.

2. A yellow discoloration of the skin.

I'CTERUS. (Named from its likeness to the plumage of the golden thrush, of which Pliny relates, that if a jaundiced person looks on one, the bird dies, and the patient recovers.) *Morbus arcuatus*, or *arquatus; Aurigo; Morbus regius; Morbus leseoli.* The jaundice. A genus of disease in the class *Cachexiæ*, and order *Impetigines*, of Cullen; characterised by yellowness of the skin and eyes; fæces white, and urine of a high colour. There are six species:—

1. *Icterus calculosus*, acute pain in the epigastric region, increasing after eating; gall-stones pass by stool.

2. *Icterus spasmodicus*, without pain, after spasmodic diseases and passions of the mind.

3. *Icterus mucosus*, without either pain, gall-stones, or spasm, and relieved by the discharge of tough phlegm by stool.

4. *Icterus hepaticus*, from an induration in the liver.

5. *Icterus gravidarum*, from pregnancy, and disappearing after delivery.

6. *Icterus infantum*, of infants.

It takes place most usually in consequence of an interrupted excretion of bile, from an obstruction in the ductus communis choledochus, which occasions its absorption into the blood-vessels. In some cases it may, however, be owing to a redundant secretion of the bile. The causes producing the first species are, the presence of biliary calculi in the gall-bladder and its ducts; spasmodic constriction of the ducts themselves; and, lastly, the pressure made by tumours in adjacent parts; hence jaundice is often an attendant symptom on a scirrhosity of the liver, pancreas, &c. and on pregnancy.

Chronic bilious affections are frequently brought on by drinking freely, but more particularly by spirituous liquors: hence they are often to be observed in the debauchee and the drinker of drams. They are likewise frequently met with in those who lead a sedentary life; and who indulge much in anxious thoughts.

A slight degree of jaundice often proceeds from the redundant secretion of bile; and a bilious habit is therefore constitutional to some people, particularly to those who reside long in a warm climate.

By attending to the various circumstances and symptoms which present themselves, we shall in general be able to ascertain, with much certainty, the real nature of the cause which has given rise to the disease.

We may be assured by the long continuance of the complaint, and by feeling the liver and other parts externally, whether or not it arises from disease of the liver, pancreas, or adjacent parts.

Where passions of the mind induce the disease, without any hardness or enlargement of the liver, or adjacent parts, and without any appearance of calculi in the fæces, or on dissection after death, we are naturally induced to conclude that the disorder was owing to a spasmodic affection of the biliary ducts.

Where gall-stones are lodged in the ducts, acute lancinating pains will be felt in the region of the parts, which will cease for a time, and then return again; great irritation at the stomach and frequent vomiting will attend, and the patient will experience an aggravation of the pain after eating. Such calculi are of various sizes, from a pea to that of a walnut; and, in some cases, are voided in a considerable number, being like the gall, of a yellowish, brownish, or green colour.

The jaundice comes on with languor, inactivity, loathing of food, flatulence, acidities in the stomach and bowels, and costiveness. As it advances in its progress, the skin and eyes become tinged of a deep yellow; there is a bitter taste in the mouth, with frequent nausea and vomiting; the urine is very high-coloured; the stools are of a grey or clayey appearance, and a dull obtuse pain is felt in the right hypochondrium, which is much increased by pressure. Where the pain is very acute, the pulse is apt to become hard and full, and other febrile symptoms to attend.

The disease, when of long continuance, and proceeding from a chronic affection of the liver, or other neighbouring viscera, is often attended with anasarcous swellings, and sometimes with ascites: also scorbutic symptoms frequently supervene.

Where jaundice is recent, and is occasioned by concretions obstructing the biliary ducts, it is probable that, by using proper means, we may be able to effect a cure; but where it is brought on by tumours of the neighbouring parts, or has arisen in consequence of other diseases attended with symptoms of obstructed viscera, our endeavours will most likely not be crowned with success. Arising during a state of pregnancy, it is of little consequence, as it will cease on parturition.

On opening the bodies of those who die of jaundice, the yellow tinge appears to pervade even the most interior part of the body; it is diffused throughout the whole of the cellular membrane, in the cartilages and bones, and even the substance of the brain is coloured with it. A diseased state of the liver, gall-bladder, or adjacent viscera is usually to be met with.

The *Icterus infantum*, or yellow gum, is a species of jaundice which affects children at or soon after, their birth, and which usually continues for some days. It has generally been supposed to arise from the meconium, impacted in the intestines, preventing the flow of bile into them. The effects produced by it, are languor, indolence, a yellow tinge of the skin, and a tendency to sleep, which is sometimes fatal, where the child is prevented from sucking.

The indications in this disease are, 1. To palliate urgent symptoms. 2. To remove the cause of obstruction to the passage of the bile into the duodenum: this is the essential part of the treatment; but the means will vary according to circumstances. When there are appearances of inflammation, of which perhaps the jaundice is symptomatic, or both produced by a gall-stone, the means explained under the head of hepatitis will be proper. If there be severe spasmodic pain, as is usual when a gall-stone is passing, the liberal use of opium and the warm bath will probably relieve it. After which, in all instances, where there is reason for supposing an obstructing cause within the duct, a nauseating emetic, or brisk cathartic, would be the most likely to force it onward: emetics, however, are hardly advisable, except in recent cases without inflammation; and calomel, seeming to promote the discharge of bile more than other cathartics, may be given in a large dose with, or after the opium. Several remedies have been recommended, on the idea that they may dissolve gall-stones; which, however, is hardly probable, unless they should have advanced to the end of the common duct: the fixed alkalies, æther with oil of turpentine, raw eggs, &c. come under this head; though the alkalies may be certainly beneficial by correcting acidity, which usually results from a deficient supply of bile to the intestines; and possibly alter the secretion of the liver so much as to prevent the formation of more concretions. When the complaint arises from scirrhous tumours, mercury is the remedy most likely to afford relief, particularly should the liver itself be diseased: but it must be used with proper caution, and hemlock, or other narcotic, may sometimes enable the system to bear it better. Where this remedy is precluded, nitric acid promises to be the best substitute, the taraxacum appears by no means so much to be depended upon. In all tedious cases the strength must be supported by the vegetable bitters or other tonics, and a nutritious diet, easy of digestion. there is often a dislike of animal food, and a craving for acids, which mostly may be indulged; indeed, when scorbutic symptoms attended, the native vegetable acids have been sometimes very serviceable. The bowels must be kept regular, and the other secretions promoted, to get rid of the bile diffused in the system; as well as to obviate febrile or inflammatory action. When accumulations of hardened fæces induce the complaint, or in the icterus infantum, cathartics may be alone sufficient to afford relief: and, in that of pregnant females, we must chiefly look to the period of delivery.

Icterus albus. The white jaundice. Chlorosis is sometimes so called.

I'CTUS. 1. A stroke or blow.

2. The pulsation of an artery.

3. The sting of a bee, or other insect.

IDÆ'US. (From ιδη, a mountain in Phrygia, their native place.) A name of the peony and blackberry.

IDE. This terminal is affixed to oxygen, chlorine, and iodine, when they enter into combination with each other, or with simple combustibles or metals in proportions not forming an acid, thus *ox-ide* of chlorine, *ox-ide* of nitrogen, *chlor-ide* of sulphur, *iod-ide* of iron.

IDE'OLOGY. (*Ideologia;* from ιδεα, a thought, and λογος, a discourse.) The doctrine or study of the understanding. "Whatever be the number and the diversity of the phenomena which belong to human intelligence, however different they appear from the other phenomena of life, though they evidently depend on the soul, it is absolutely necessary to consider them as the result of the action of the brain, and to make no distinction between them and the other phenomena that depend on the actions of that organ. The functions of the brain are absolutely subject to the same laws as the other functions; they develope and go to decay in the progress of age; they are modified by habit, sex, temperament, and individual disposition; they become confused, weakened, or elevated in diseases; the physical injuries of the brain weaken, or destroy them; in a word, they are not susceptible of any explanation more than the other actions of the organ; and setting aside all hypothetical ideas, they are capable of being studied only by observation and experience.

We must also be cautious in imagining that the study of the functions of the brain is more difficult than that of the other organs, and that it appertains peculiarly to metaphysics. By keeping close to observation, and avoiding carefully any theory, or conjecture, this study becomes purely physiological, and perhaps it is easier than the most part of the other functions, on account of the facility with which the phenomena can be produced and observed. The innumerable phenomena which form the intellect of man, are only modifications of the faculty of perception. If they are examined attentively, this truth, which is well illustrated by modern metaphysicians, will be found very clear.

There are four principal modifications of the faculty of perception:

1st. *Sensibility*, or the action of the brain, by which we receive impressions, either from within, or from without.

2d. The *Memory*, or the faculty of reproducing impressions, or sensations formerly received.

3d. The faculty of perceiving the relations which sensations have to each other, or the *Judgment.*

4th. The *Desires*, or the *Will.*

The study of the understanding, from whatever cause, is not at present an essential part of physiology; the science which treats particularly of it is *Ideology*. Whoever may wish to acquire an extensive knowledge on this interesting subject, should consult the works of Bacon, Locke, Condillac, Cabanis, and especially the excellent book of Destutt Tracy, entitled "Elements of Ideology."

IDIOCRA'SIA. See *Idiosyncrasy.*

IDIOPA'THIC. (*Idiopathicus;* from ιδιος, peculiar, and παθος, an affection.) A disease which does not depend on any other disease, in which respect it is opposed to a symptomatic disease, which is dependent on another.

IDIOSY'NCRASY. (*Idiosyncrasia;* from ιδιος, peculiar, συν, with, and κρασις, a temperament.) A peculiarity of constitution, in which a person is affected by certain agents, which, if applied to a hundred other persons, would produce no effect: thus some people cannot see a finger bleed without fainting; and thus violent inflammation is induced on the skin of some persons by substances that are perfectly innocent to others.

Idiot'ropia. (From ιδιος, peculiar, and τρεπω, to turn.) The same as *Idiosyncrasia.*

IDOCRASE. See *Vesuvian.*

IGASURIC ACID. *Acidum Igusaricum.* Pelletier and Caventou, in their elegant researches in the *faba Sancti Ignatii, et nux vomica*, having observed that these substances contained a new vegetable base (strychnine) in combination with an acid, sought to separate the latter, in order to determine its nature. It appeared to them to be new, and they called it igasuric acid, from the Malay name by which the natives designate in the Indies the *faba Sancti Ignatii.* This bean, according to these chemists, is composed of igasurate of strychnine, a little wax, a concrete oil, a yellow colouring matter, gum, starch, bassorine, and vegetable fibre.

To extract the acid, the rasped bean must be heated in æther, in a digester, with a valve of safety. Thus the concrete oil, and a little igasurate of strychnine, are dissolved out. When the powder is no longer acted on by the æther, they subject it, at several times, to the action of boiling alkohol, which carries off the oil which had escaped the æther, as also wax, which is deposited on cooling, some igasurate of strychnine, and colouring matter. All the alkoholic decoctions are united, filtered, and evaporated. The brownish-yellow residuum is diffused in water: magnesia is now added, and the whole is boiled together for some minutes. By this means, the igasurate is decomposed, and from this decomposition there results free strychnine, and a sub-igasurate of magnesia, very little soluble in water. Washing with cold water removes almost completely the colouring matter, and boiling alkohol then separates the strychnine, which falls down as the liquid cools. Finally, to procure igasuric acid from the sub-igasurate of magnesia, which remains united to a small quantity of colouring matter, we must dissolve the magnesian salt in a great body of boiling distilled water; concentrate the liquor, and add to it acetate of lead, which immediately throws down the acid in the state of an igasurate of lead. This compound is then decomposed, by transmitting a current of sulphuretted hydrogen through it, diffused in 8 or 10 times its weight of boiling water.

This acid, evaporated to the consistence of syrup, and left to itself, concretes in hard and granular crystals. It is very soluble in water, and in alkohol. Its taste is acid and very styptic. It combines with the alkaline and earthy bases, forming salts soluble in water and alkohol. Its combination with barytes is very soluble, and crystallises with difficulty, and mushroom-like. Its combination with ammonia, when perfectly neutral, does not form a precipitate with the salts of silver, mercury, and iron; but it comports itself with the salts of copper in a peculiar manner, and which seems to characterise the acid of *strychnos* (for the same acid is found in *nux-vom-*

ica, and in snake-wood, *bois de couleuvre* :) this effect consists in the decomposition of the salts of copper, by its ammoniacal compound. These salts pass immediately to a green colour, and gradually deposite a greenish-white salt, of very sparing solubility in water. The acid of *strychnos* seems thus to resemble meconic acid; but it differs essentially from it, by its action with salts of iron, which immediately assume a very deep red colour with the meconic acid: an effect not produced by the acid of *strychnos*. The authors, after all, do not positively affirm this acid to be new and peculiar

IGNA'TIA. (So named by Linnæus, because the seeds are known in the materia medica by the name of Saint Ignatius beans.) The name of a genus of plants. Class, *Pentandria;* Order, *Monogynia.*

Ignatia amara. The systematic name of the plant which affords St. Ignatius's bean; *Faba indica; Faba Sancti Ignatii; Faba febrifuga.* These beans are of a roundish figure, very irregular and uneven, about the size of a middling nutmeg, semitransparent, and of a hard, horny texture. They have a very bitter taste, and no considerable smell. They are said to be used in the Philippine islands in all diseases, acting as a vomit and purgative. Infusions are given in the cure of intermittents, &c.

Ignatii faba. See *Ignatia amara.*

IGNATIUS'S BEAN. See *Ignatia amara.*

I'GNIS. Fire. 1. Van Helmont, Paracelsus, and other alchemists, applied this term to what they considered as universal solvents.

2. In medicine, the older writers used it to express several diseases characterised by external redness and heat.

Ignis calidus. A hot fire; a gangrene: also a violent inflammation, just about to degenerate into a gangrene, were formerly so called by some.

Ignis fatuus. A luminous appearance or flame, frequently seen in the night in different country places, and called in England *Jack with a lantern*, or *Will with the wisp*. It seems to be mostly occasioned by the extrication of phosphorus from rotting leaves and other vegetable matters. It is probable, that the motionless ignes fatui of Italy which are seen nightly on the same spot, are produced by the slow combustion of sulphur, emitted through clefts and apertures in the soil of that volcanic country.

Ignis frigidus. A cold fire. A sphacelus was so called, because the parts that are so affected become as cold as the surrounding air.

Ignis persicus. A name of the erysipelas, also of the carbuncle. See *Anthrax.*

Ignis rotæ. Fire for fusion. It is when a vessel which contains some matter for fusion is surrounded with live, *i. e.* red-hot coals.

Ignis sacer. A name of erysipelas, and of a species of herpes.

Ignis sapientium. Heat of horse-dung.

Ignis sancti antonii. See *Erysipelas.*

Ignis sylvaticus. See *Impetigo.*

Ignis volagrius. See *Impetigo.*

Ignis volaticus. See *Erysipelas.*

I'kan radix. A somewhat oval, oblong, compressed root, brought from China. It is extremely rare, and would appear to be the root of some of the orchis tribe.

I'laphis. A name in Myrepsus for the burdoch. See *Arctium lappa.*

I'lech. By this word, Paracelsus seems to mean a first principle.

Ilei'dos. In the Spagyric language it is the elementary air.

I'leon cruentum. Hippocrates describes it in lib. De Intern. Affect. In this disease, as well as in the scurvy, the breath is foetid, the gums recede from the teeth, hæmorrhages of the nose happen, and sometimes there are ulcers in the legs, but the patient can move about.

I'LEUM. (From ειλεω, to turn about; from its convolutions.) *Ileum intestinum.* The last portion of the small intestines, about fifteen hands' breadth in length, which terminates at the valve of the cæcum. See *Intestine.*

ILEUS. See *Iliac passion.*

I'LEX. (The name of a genus of plants in the Linnæan system. Class, *Tetrandria.* Order, *Tetragynia.*) The holly.

Ilex aquifolium. The systematic name of the common holly. *Aquifolium.* The leaves of this plant, *Ilex—foliis ovatis acutis spinosis*, of Linnæus, have been known to cure intermittent fevers; and an infusion of the leaves, drank as tea, is said to be a preventive against the gout.

Ilex cassine. *Cassina; Apalachine gallis.* This tree grows in Carolina; the leaves resemble those of senna, blackish when dried, with a bitter taste, and aromatic smell. They are considered as stomachic and stimulant. They are sometimes used as expectorants; and when fresh are emetic.

I'LIA. (The plural of *Ile*, ειλη.)

1. The flanks, or that part in which are enclosed the small intestines.

2. The small intestines.

I'LIAC. (*Iliacus; from ileum intestrium.*) Belonging to the ilium, an intestine so called.

Iliac arteries. *Arteriæ iliacæ.* The arteries so called are formed by the bifurcation of the aorta, near the last lumbar vertebra. They are divided into *internal* and *external.* The *internal iliac*, also called the *hypogastric artery*, is distributed in the fœtus into six, and in the adult into five branches, which are divided about the pelvis, viz. the little iliac, the gluteal, the ischiatic, the pudical, and the obturatory; and in the fœtus the umbilical. The *external iliac* proceeds out of the pelvis through Poupart's ligament, to form the femoral artery.

Iliac passion. (Ειλεος, ιλεος, ειλειος, is described as a kind of nervous colic, the seat of which is the ilium.) *Passio iliaca; Volvulus; Miserere mei; Convolvulus; Chordapsus; Tormentum.* A violent vomiting, in which the fæcal portion of the food is voided by the mouth. It is produced by many morbid conditions of the bowels, by inflammatory affections of the abdominal viscera, and by herniæ.

Iliac region. The side of the abdomen, between the ribs and the hips.

ILI'ACUS. The name of muscles, regions or diseases, situated near to or connected with, parts about the ilia or flanks.

Iliacus internus. *Iliacus* of Winslow. *Iliaco trachanten* of Dumas. A thick, broad, and radiated muscle, which is situated in the pelvis, upon the inner surface of the ilium. It arises fleshy from the inner lip of the ilium, from most of the hollow part, and likewise from the edge of that bone, between its anterior superior spinous process and the acetabulum. It joins with the psoas magnus, where it begins to become tendinous, and passing under the ligamentum Falopii, is inserted in common with that muscle. The tendon of this muscle has been seen distinct from that of the psoas, and, in some subjects, it has been found divided into two portions. The iliacus internus serves to assist the psoas magnus in bending the thigh, and in bringing it directly forwards.

ILI′ADUM. *Iliadus.* The first matter of all things, consisting of mercury, salt, and sulphur. These are Paracelsus's three principles. His *iliadus* is also a mineral spirit, which is contained in every element, and is the supposed cause of diseases.

Ilia′ster. Paracelsus gives this name to the occult virtue of nature, whence all things have their increase.

ILI′NGOS. (From ιλιγξ, a vortex.) A giddiness, in which all things appear to turn round, and the eyes grow dim.

Ili′scus. Avicenna says, it is madness caused by love.

I′LIUM OS. (From *ilia*, the small intestines; so named because it supports the ilia.) The haunch-bone. The superior portion of the os innominatum, which, in the fœtus, is a distinct bone. See *Innominatum os.*

ILLA. See *Ula.*

ILLE′CEBRA. (From ειλεω, to turn; because its leaves resemble worms.) See *Sedum acre.*

ILLI′CIUM. (*Illicium, ab illiciendo;* denoting an enticing plant, from its being very fragrant and aromatic.) The name of a genus of plants in the Linnæan system. Class, *Polyandria;* Order, *Polygynia.*

Illicium anisatum. The systematic name of the yellow-flowered aniseed-tree: the seeds of which are called the star aniseed. *Anisum stellatum; Anisum sinense; Semen badian.* They are used with the same views as those of the *Pimpinella anisum.* The same tree is supposed to furnish the aromatic bark, called *cortex anisi stellati,* or *cortex lavola.*

ILLO′SIS. (From ιλλος, the eye.) A distortion of the eyes.

Illutame′ntum. An ancient form of an external medicine, like the *Ceroma,* with which the limbs of wrestlers, and others delighting in like exercises, were rubbed, especially after bathing; an account of which may be met with in Bactius De Thermis.

Illuta′tio. (From *in,* and *lutum,* mud.) Illutation. A besmearing any part of the body with mud, and renewing it as it grows dry, with a view of heating, drying, and discussing. It was chiefly done with the mud found at the bottom of mineral springs.

I′llys. (From ιλλος, the eye.) A person who squints, or with distorted eyes.

I′lys. (From ιλυς, mud.) 1. The fæces of wine. An obsolete term.

2. The sediment in stools, which resemble fæces of wine.

3. The sediment in urine, when it resembles the same.

Imbeci′llitas oculorum. Celsus speaks of the *Nyctalopia* by this name.

Imbibi′tio. (From *imbibo,* to receive into.) An obsolete term. In chemistry for a kind of cohobation, when the liquor ascends and descends upon a solid substance, till it is fixed therewith.

IMBRICATUS. Imbricated: like tiles upon a house. A term applied to leaves, as those of the *Euphorbia paralia.*

IMMERSUS. Immersed: plunged under water—*folia immersa:* leaves which are naturally under the water, and are different from those which naturally float. See *Leaf.*

It is remarked by Linnæus, that aquatic plants have their lower, and mountainous ones their upper, leaves most divided, by which they better resist the action of the stream in one case, and of the wind in the other.

Imme′rsus. A term given by Bartholine, and some other anatomists, to the *Subscapularis* muscle, because it was hidden, or, as it were, sunk.

IMPA′TIENS. (From *in,* not, and *patior,* to suffer; because its leaves recede from the hand with a crackling noise, as impatient of the touch, or from the great elasticity of the sutures of its seed vessel which is completely impatient of the touch, curling up with the greatest velocity, and scattering round the seeds, the instant any extraneous body comes in contact with it.) The name of a genus of plants. Class, *Pentandria;* Order, *Monogynia.*

IMPERATO′RIA. (From *impero,* to overcome: so named because its leaves extend and overwhelm the lesser herbs which grow near it.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia.*

2. The pharmacopœial name of the master-work. See *Imperatoria osthruthium.*

Imperatoria ostruthium. The systematic name of the master-wort. *Imperatoria; Magistrantia.* The roots of this plant are imported from the Alps and Pyrenees, notwithstanding it is indigenous to this island: they have a fragrant smell, and a bitterish pungent taste. The plant, as its name imports, was formerly thought to be of singular efficacy; and its great success, it is said, caused it to be distinguished by the name of *divinum remedium.* At present, it is considered merely as an aromatic, and consequently is superseded by many of that class which possess superior qualities.

IMPETI′GINES. (The plural of *impetigo;* from *impeto,* to infest.) An order in the class *Cachexiæ* of Cullen, the genera of which are characterised by cachexia deforming the external parts of the body with tumours, eruptions, &c.

IMPETI′GO. *Ignis sylvaticus; Ignis volagrius.* A disease of the skin, variously described by authors, but mostly as one, in which several red, hard, dry, prurient spots arise in the face and neck, and sometimes all over the body, and disappear by furfuraceous or tender scales.

Impetum faciens. See *Vis vitæ.*

IMPETUSA. Force or motion.

I′mpia herba. (From *in,* not, and *pius,* good; because it grows only on barren ground.) A name given to cudweed. See *Gnaphalium.*

IMPLICATED. Celsus, Scribonius, and some others, call those parts of physic so, which have a necessary dependence on one another; but the term has been more significantly applied, by Bellini, to fevers, where two at a time afflict a person, either of the same kind, as a double tertian; or, of different kinds, as an intermittent tertian, and a quotidian, called a *Semitertian.*

Implu′vium. (From *impluo,* to shower upon.) 1. The shower-bath.

2. An embrocation.

IMPOSTHUMA. A term corrupted from *impostem* and *apostem.* An abscess.

IMPREGNA′TION. *Impregnatio.* See *Conception* and *Generation.*

INANI′TIO. (From *inanio,* to empty.) Inanition. Applied to the body or vessels, it means emptiness; applied to the mind, it means a defect of its powers.

INCANTA′TION. *Incantatio; Incantamentum.* A way of curing diseases by charms, defended by Paracelsus, Helmont, and some other chemical enthusiasts.

INCANUS. Hoary. Applied to stems which are covered with a kind of scaly mealiness, as that of the *Artemisia absinthium*, and *Atriplex portulacoides*.

Ince'ndium. (From *incendo*, to burn.) A burning fever, or heat.

Ince'nsio. 1. A burning fever.

2. A hot inflammatory tumour.

Incerni'culum. (From *incerno*, to sift.)

1. A strainer, or sieve.

2. A name for the pelvis of the kidney, from its office as a strainer.

Incide'ntia. (From *incido*, to cut.) Medicines which consist of pointed and sharp particles, as acids, and most salts, which are said to incide or cut the phlegm, when they break it so as to occasion its discharge.

INCINERA'TION. (From *incinero*, to reduce to ashes.) *Incineratio*. The combustion of vegetable or animal substances, for the purpose of obtaining their ashes or fixed residue.

INCISI'VUS. (From *incido*, to cut.) A name given to some muscles, &c.

Incisivus inferior. See *Levator labii inferioris*.

Incisivus lateralis. See *Levator labii superioris alæque nasi*.

Incisivus medius. See *Depressor labii superioris alæque nasi*.

INCI'SOR. (*Dentes incisores;* from *incido*, to cut, from their use in cutting the food.) The four front teeth of both jaws are called incisors, because they cut the food. See *Teeth*.

INCISO'RIUM. (From *incido*, to cut.) A table whereon a patient is laid for an operation.

Incisorium foramen. A name of the foramen, which lies behind the dentes incisores of the upper jaw.

INCISUS. (From *incido*, to cut.) Cut. A term applied in botany, synonymously with *dissectus*, to leaves; as those of the *Geranium dissectum*.

INCONTINE'NTIA. (From *in*, and *contineo*, to contain.) Inability to retain the natural evacuations. Hence we say, incontinence of urine, &c.

Incrassa'ntia. (*Incrassans;* from *incrasso*, to make thick.) Medicines which thicken the fluids.

I'NCUBUS. (From *incubo*, to lie upon; because the patient fancies that something lies upon his chest.) See *Oneirodynia*.

INCURVUS. Curved inwards: applied to leaves; as in *Erica empetrifolia*.

INCUS. (A smith's anvil; from *incudo*, to smite upon: so named from its likeness in shape to an anvil.) The largest and strongest of the bones of the ear in the tympanum. It is divided into a body and two crura. Its body is situated anteriorly, is rather broad and thick, and has two eminences and two depressions, both covered with cartilage, and intended for the reception of the head of the malleus. Its shorter crus extends no farther than the cells of the mastoid apophysis. Its longer crus, together with the manubrium of the malleus, to which it is connected by a ligament, is of the same extent as the shorter; but its extremity is curved inwards, to receive the os orbiculare, by the intervention of which it is united with the stapes.

I'NDEX. (From *indico*, to point out; because it is generally used for such purposes.) The fore-finger.

Indian arrow-root. See *Maranta*.

Indian cress. See *Tropæolum majus*.

Indian date-plum. See *Diospyros lotus*.

Indian leaf. See *Laurus cassia*.

Indian-pink. See *Spigelia*.

Indian rubber. See *Caoutchouc*.

Indian wheat. See *Zea mays*.

India'na radix. Ipecacuanha.

I'ndica camotes. Potatoes.

INDICANT. (*Indicans;* from *indico*, to show.) That from which the indication is drawn, which is in reality the proximate cause of a disease.

Indicating days. Critical days.

INDICA'TION. (*Indicatio;* from *indico*, to show.) An indication is that which demonstrates in a disease what ought to be done. It is threefold: preservative, which preserves health; curative, which expels a present disease; and vital, which respects the powers and reasons of diet. The scope from which indications are taken, or determined, is comprehended in this distich:

—— *Ars, ætas, regio, complexio, virtus,*
Mos et symptoma, repletio, tempus, et usus.

INDICATOR. (From *indico*, to point: so named from its office of extending the index, or fore-finger.) An extensor muscle of the forefinger, situated chiefly on the lower and posterior part of the fore-arm. *Extensor indicis* of Cowper. *Extensor secundii internodii indicis proprius, vulgo indicator* of Douglas; and *Cubitosus phalangettien de l'index* of Dumas. It arises, by an acute fleshy beginning, from the middle of the posterior part of the ulna; its tendon passes under the same ligament with the extensor digitorum communis, with part of which it is inserted into the posterior part of the forefinger.

Indicum lignum. Logwood.

Indicus morbus. The venereal disease.

INDI'GENOUS. (*Indigenus; indigena ab indu, i. e. in et geno, i. e. gigno*, to beget.) Applied to diseases, plants, and other objects which are peculiar to any country.

INDIGO. A blue colouring matter extracted from the *Indigofera tinctoria*. Anil, or the indigo plant.

INDIGOFERA. (From *indigo*, and *fero*, to bear.) The name of a genus of plants. Class, *Diadelphia;* Order, *Decandria*.

Indigofera tinctoria. The systematic name of the plant which affords indigo.

INDUCIUM. (From *induco*, to cover, or draw over.) A covering. 1. A shirt.

2. The name of the amnios, from its covering the fœtus like a shirt.

3. Wildenow and Swart's name for the involucrum, or thin membraneous covering of the fructification of ferns.

Its varieties are,

1. *Inducium planum*, flat: as in the genus *Polypodium*.

2. *I. peltatum*, connected with the seed by a filament or stalk; as in *Aspidium filixmas*.

3. *I. corniculatum*, round and hollow; as in *Equisetum*.

Indura'ntia. (From *induro*, to harden.) Medicines which harden.

INEQUALIS. Unequal. Applied to a leaf when the two halves are unequal in dimensions and the base end parallel; as in *Eucalyptus resinifera*.

INERMIS. (From *in*, priv. and *arma*.) Unarmed: opposed, in designating leaves, to such as are spinous.

Ine'sis. (From ιναω, to evacuate.) *Inethus*. An evacuation of the humours.

INFECTION. See *Contagion*.

INFERNAL. A name given to a caustic, *lapis infernalis*, from its strong burning property. See *Argenti nitras*.

Infibula'tio. (From *infibulo*, to button together.) An impediment to the retraction of the prepuce.

INFLAMMABLE. Chemists distinguish by this term such bodies as burn with facility, and flame in an increased temperature.

Inflammable air. See *Hydrogen gas.*

Inflammable air, heavy. See *Carburetted hydrogen gas.*

INFLAMMATION. (*Inflammatio, onis.* f.; from *inflammo*, to burn.) *Phlogosis; Phlegmasia.* A disease characterised by heat, pain, redness, attended with more or less of tumefaction and fever. Inflammation is divided into two species, viz. phlegmonous and erysipelatous.

Besides this division, inflammation is either acute or chronic, local or general, simple or complicated with other diseases.

1. *Phlegmonous inflammation* is known by its bright red colour, tension, heat, and a circumscribed, throbbing, painful tumefaction of the part; tending to suppuration. Phlegmon is generally used to denote an inflammatory tumour, situated in the skin or cellular membrane. When the same disease affects the viscera, it is usually called phlegmonous inflammation.

2. *Erysipelatous inflammation* is considered as an inflammation of a dull red colour, vanishing upon pressure, spreading unequally, with a burning pain, the tumour scarcely perceptible, ending in vesicles, or desquamation. This species of inflammation admits of a division into erythema, when there is merely an affection of the skin, with very little of the whole system; and erysipelas, when there is general affection of the system.

The fever attending erysipelatous inflammation is generally synochus, or typhus, excepting when it affects very vigorous habits, and then it may be synocha. The fever attending phlegmonous inflammation is almost always synocha. Persons in the prime of life, and in full vigour, with a plethoric habit of body, are most liable to the attacks of phlegmonous inflammation; whereas, those advanced in years, and those of a weak habit of body, irritable, and lean, are most apt to be attacked with erysipelatous inflammation.

Phlegmonous inflammation terminates in resolution, suppuration, gangrene, and scirrhus, or induration. Resolution is known to be about to take place when the symptoms gradually abate; suppuration, when the inflammation does not readily yield to proper remedies, the throbbing increases, the tumour points externally, and rigors come on. Gangrene is about to take place when the pain abates, the pulse sinks, and cold perspirations come on. Scirrhus, or induration, is known by the inflammation continuing a longer time than usual; the tumefaction continues, and a considerable hardness remains. This kind of tumour gives little or no pain, and, when it takes place, it is usually the sequel of inflammation affecting glandular parts. It sometimes, however, is accompanied with lancinating pains, ulcerates, and becomes cancerous.

Erythematous inflammation terminates in resolution, suppuration, or gangrene. The symptoms of inflammation are accounted for in the following way:—

The redness arises from the dilatation of the small vessels, which become sufficiently large to admit the red particles in large quantities; it appears also to occur, in some cases from the generation of new vessels. The swelling is caused by the dilatation of the vessels, the plethoric state of the arteries and veins, the exudation of coagulable lymph into the cellular membrane, and the interruption of absorption.

In regard to the augmentation of heat, as the thermometer denotes very little increase of temperature, it appears to be accounted for from the increased sensibility of the nerves, which convey false impressions to the sensorium. The pain is occasioned by a deviation from the natural state of the parts, and the unusual condition into which the nerves are thrown. The throbbing depends on the action of the arteries.

Blood taken from a person labouring under active inflammation, exhibits a yellowish white crust on the surface; this is denominated the buffy coriaceous, or inflammatory coat. This consists of a layer of coagulable lymph, almost destitute of red particles. Blood, in this state, is often termed sizy. The colouring part of the blood is its heaviest constituent; and, as the blood of a person labouring under inflammation is longer coagulating than healthy blood, it is supposed that the red particles have an opportunity to descend to a considerable depth from the surface before they become entangled. The buffy coat of blood is generally the best criterion of inflammation; there are a few anomalous constitutions in which this state of blood is always found; but these are rare.

The occasional and exciting causes of inflammation are very numerous; they, however, may generally be classed under external violence, produced either by mechanical or chemical irritation, changes of temperature, and stimulating foods. Fever often seems to be a remote cause; the inflammation thus produced is generally considered as critical. Spontaneous inflammation sometimes occurs when no perceptible cause can be assigned for its production. Scrophula and syphilis may be considered as exciting causes of inflammation.

With regard to the proximate cause, it has been the subject of much dispute. Galen considered phlegmon to be produced by a superabundance of the humour sanguineus. Boerhaave referred the proximate cause to an obstruction in the small vessels, occasioned by a lentor of the blood. Cullen and others attributed it rather to an affection of the vessels than a change of the fluids.

The proximate cause, at the present period, is generally considered to be a morbid dilatation, and increased action of such arteries as lead and are distributed to the inflamed part.

Inflammation of the bladder. See *Cystitis.*

Inflammation of the brain. See *Phrenitis.*

Inflammation of the eyes. See *Ophthalmia.*

Inflammation of the intestines. See *Enteritis.*

Inflammation of the kidneys. See *Nephritis.*

Inflammation of the liver. See *Hepatitis.*

Inflammation of the lungs. See *Pneumonia.*

Inflammation of the peritonæum. See *Peritonitis.*

Inflammation of the pleura. See *Pleuritis.*

Inflammation of the stomach. See *Gastritis.*

Inflammation of the testicle. See *Orchitis.*

Inflammation of the uterus. See *Hysteritis.*

INFLA'TIO. (From *inflo*, to puff up.) A windy swelling. See *Pneumatosis.*

Infla'tiva. (*Inflativus*; from *inflo*, to puff up with wind.) Medicines or food which cause flatulence.

INFLATUS. Inflated. In botany applied to vesiculated parts, which naturally contain only air; as *legumen inflatum*, seen in *Astragalus vesicarius*, and the distended and hollow perianths of the *Cucubalus behen*, and *Physalis alkekengi* in fruit.

INFLEXUS. Curved inwards; synonymous to *incurvus*, as applied to leaves, petals, &c. See *Incurvus*. The petals of the *Pimpinella*, and *Chærophyllum*, are described as *inflexa*.

INFLORESCENCE. (*Inflorescentia*, from *infloresco*; to flower, or blossom.) A term used by Linnæus to express the particular manner in which flowers are situated upon a plant, denominated by preceding writers, *modus florendi*, or manner of flowering.

It is divided into *simple*, when solitary, and *compound*, when many flowers are placed together in one place.

The first affords the following distinctions:

1. *Flos pedunculatus*, furnished with a stalk; as in *Gratiolus* and *Vinca*.
2. *F. sessilis*, adhering to the plant without a flower-stalk; as in *Daphne mezerium*, and *Zinia pauciflora*.
3. *F. caulinus*, when on the stem.
4. *F. rameus*, when on the branch.
5. *F. terminalis*, when on the apex of the stem, or branch; as *Paris quadrifolia*, and *Chrysanthemum leucanthemum*.
6. *F. axillaris*, in the axilla; as in *Convallaria multiflora*.
7. *F. foliaris*, on the surface of the leaf; as in *Phyllanthus*.
8. *F. radicalis*, on the root; as *Carlina acaulis*, *Crocus*, and *Colchicum*.
9. *F. latitans*, concealed in a fleshy receptacle; as in *Ficus carica*.

Again, it is said to be,

1. *Alternate*; as in *Polyanthes tuberosa*.
2. *Opposite*; as in *Passiflora hirsuta*.
3. *Unilateral*, hanging all to one side; as *Erica herbacea*, and *Silene amœna*.
4. *Solitary*; as in *Campanula speculum*, and *Carduus tuberosus*.

The second, or compound inflorescence has the following kinds:

1. The *verticillus*, or whirl.
2. The *capitulum*, or tuft.
3. The *spica*, or spike.
4. The *racemus*, or cluster.
5. The *corymbus*, or corymb.
6. The *umbella*, or umbel.
7. The *cyma*, or cyme.
8. The *fasciculus*, or fascicle.
9. The *panicula*, or panicle.
10. The *thyrsus*, or bunch.
11. The *spadix*, or sheath.
12. The *amentum*, or catkin.

INFLUE'NZA. (The Italian word for influence.) The disease is so named because it was supposed to be produced by a peculiar influence of the stars. See *Catarrhus à contagione*.

INFRASCAPULA'RIS. (From *infra*, beneath, and *scapula*, the shoulder-blade.) A muscle named from its position beneath the scapula. See *Subscapularis*.

INFRASPINA'TUS. (From *infra*, beneath, and *spina*, the spine.) A muscle of the humerus, situated on the scapula. It arises fleshy, from all that part of the dorsum scapulæ which is below its spine; and from the spine itself, as far as the cervix scapulæ. The fibres run obliquely towards a tendon in the middle of a muscle, which runs forwards, and adheres to the capsular ligament. It is inserted by a flat thick tendon, into the upper and outer part of the large protuberance on the head of the os humeri. Its use is to roll the os humeri outwards, to assist in raising and supporting it when raised, and to pull the ligament from between the bones. This muscle and the supra spinatus are covered by an aponeurosis, which extends between the costæ, and edges of the spine of the scapula, and gives rise to many of the muscular fibres.

INFUNDIBULIFORMIS. Funnel-shaped. Applied to the corolla of plants; as in *Pulmonarii*.

INFUNDI'BULUM. (From *infundo*, to pour in.) 1. A canal that proceeds from the vulva of the brain to the pituitary gland in the sella turcica.

2. The beginnings of the excretory duct of the kidney, or cavities into which the urine is first received, from the secretory cryptæ, are called *infundibula*.

INFUSION. (*Infusum*; from *infundo*, to pour in.) *Infusio*. A process that consists in pouring water of any required degree of temperature on such substances as have a loose texture, as thin bark, wood in shavings, or small pieces, leaves, flowers, &c. and suffering it to stand a certain time. The liquor obtained by the above process is called an *infusion*. The following are among the most approved infusions.

INFU'SUM. See *Infusion*.

INFUSUM ANTHEMIDIS. Infusion of camomile. Take of camomile-flowers, two drachms; boiling water, half a pint. Macerate for ten minutes, in a covered vessel, and strain. For its virtues, see *Anthemis nobilis*.

INFUSUM ARMORACIÆ COMPOSITUM. Compound infusion of horse-radish. Take of fresh horse-radish root, sliced, mustard-seeds bruised, of each one ounce; boiling water, a pint. Macerate for two hours, in a covered vessel, and strain; then add compound spirit of horse-radish, a fluid ounce. See *Cochlearia armoracia*.

INFUSUM AURANTII COMPOSITUM. Compound infusion of orange-peel. Take of orange-peel, dried, two drachms; lemon-peel, fresh, a drachm; cloves, bruised, half a drachm; boiling water, half a pint. Macerate for a quarter of an hour, in a covered vessel, and strain. See *Citrus aurantium*.

INFUSUM CALUMBÆ. Infusion of calumba. Take of Calumba-root, sliced, a drachm; boiling water, half a pint. Macerate for two hours in a covered vessel, and strain. See *Calumba*.

INFUSUM CARYOPHYLLORUM. Infusion of cloves. Take of cloves, bruised, a drachm; boiling water, half a pint. Macerate for two hours, in a covered vessel, and strain. See *Eugenia caryophyllata*.

INFUSUM CASCARILLÆ. Infusion of cascarilla. Take of cascarilla bark, bruised, half an ounce; boiling water, half a pint. Macerate for two hours, in a covered vessel, and strain. See *Croton cascarilla*.

INFUSUM CATECHU COMPOSITUM. Compound infusion of catechu. Take of extract of catechu, two drachms and a half; cinnamon bark, bruised, half a drachm; boiling water, half a pint. Macerate for an hour, in a covered vessel, and strain. See *Acacia catechu*.

INFUSUM CINCHONÆ. Infusion of cinchona. Take of lance-leaved cinchona bark, bruised, half an ounce; boiling water, half a pint. Macerate for two hours, in a covered vessel, and strain. See *Cinchona*.

INFUSUM CUSPARIÆ. Infusion of cusparia. Take of cusparia bark, bruised, two drachms; boiling water, half a pint. Macerate for two hours, in a covered vessel, and strain. See *Cusparia febrifuga*.

INFUSUM DIGITALIS. Infusion of fox-glove. Take of purple fox-glove leaves, dried, a drachm; boiling water, half a pint. Macerate for four hours, in a covered vessel, and strain; then add spirit of cinnamon, half a fluid ounce. See ***Digitalis purpurea***.

Infusum gentianæ compositum. Compound infusion of gentian. Take of gentian-root, sliced, orange-peel, dried, of each a drachm; lemon-peel, fresh, two drachms; boiling water, twelve fluid ounces. Macerate for an hour in a covered vessel, and strain. See *Gentiana lutea.*

Infusum lini. Infusion of linseed. Take of linseed, bruised, an ounce; liquorice root, sliced, half an ounce; boiling water, two pints. Macerate for two hours, near the fire, in a covered vessel, and strain. See *Linum usitatissimum.*

Infusum quassiæ. Infusion of quassia. Take of quassia wood, a scruple; boiling water, half a pint. Macerate for two hours, and strain. See *Quassia amara.*

Infusum rhei. Infusion of rhubarb. Take of rhubarb-root, sliced, a drachm; boiling water, half a pint. Macerate for two hours, and strain. See *Rheum.*

Infusum rosæ. Take of the petals of red rose, dried, half an ounce; boiling water, two pints and a half; dilute sulphuric acid, three fluid drachms; double-refined sugar, an ounce and a half. Pour the water upon the petals of the rose in a glass vessel; then add the acid, and macerate for half an hour. Lastly, strain the infusion, and add the sugar to it. See *Rosa Gallica.*

Infusum sennæ. Infusion of senna. Take of senna-leaves, an ounce and a half; ginger-root, sliced, a drachm; boiling water, a pint. Macerate for an hour, in a covered vessel, and strain the liquor. See *Cassia senna.*

Infusum simaroubæ. Infusion of simarouba. Take of simarouba-bark, bruised, half a drachm; boiling water, half a pint. Macerate for two hours, in a covered vessel, and strain. See *Quassia simarouba.*

Infusum tabaci. Infusion of tobacco. Take of tobacco-leaves, a drachm; boiling water, a pint. Macerate for an hour, in a covered vessel, and strain. See *Nicotiana.*

INGENHOUZ, John, was born at Breda, in 1730. Little is known of his early life; but in 1767, he came to England to learn the Suttonian method of inoculation. In the following year he went to Vienna, to inoculate some of the imperial family, for which service he received ample honours; and shortly after performed the same operation on the Grand Duke of Tuscany, when he returned to this country, and spent the remainder of his life in scientific pursuits. In 1779, he published "Experiments on Vegetables," discovering their great power of purifying the air, in sunshine, but injuring it in the shade and night. He was also author of several papers in the Philosophical Transactions, being an active member of the Royal Society. He died in 1799.

INGLUVIES. 1. Gluttony.

2. The claw, crop, or gorge of a bird.

INGRASSIAS, John Philip, was born in Sicily, and graduated at Padua in 1537 with singular reputation; whence he was invited to a professorship in several of the Italian schools; but he gave the preference to Naples, where he distinguished himself greatly by his learning and judgment. At length he returned to his native island, and settled in Palermo, where he was also highly esteemed; and in 1563 made first physician to that country by Philip II. of Spain, to whom it then belonged. This office enabled him to introduce excellent regulations into the medical practice of the island, and when the plague raged there in 1575, the judicious measures adopted by him arrested its progress; whence the magistrates decreed him a large reward, of which, however, he only accepted a part, and applied that to religious uses. He died in 1580, at the age of 70. He cultivated anatomy with great assiduity, and is reckoned one of the improvers of that art, especially in regard to the structure of the cranium, and the organ of hearing. He is said also to have discovered the seminal vesicles. He published several works, particularly an account of the plague; and a treatise "De Tumoribus præter Naturam," which is chiefly a commentary on Avicenna, but is deserving of notice, as containing the first modern description of Scarlatina, under the name of Rossalia; and perhaps the first account of varicella, which he called crystalli. But his principal work was published by his nephew in 1603, entitled, "Commentaries on Galen's Book concerning the Bones."

Ingravidation. (From *ingravidor*, to be great with child.) The same as impregnation, or going with child.

I'NGUEN. (*Inguen, inis.* n.) The groin. The lower and lateral part of the abdomen, above the thigh.

INGUINAL. *Inguinalis.* Appertaining to the groin.

Inguinal hernia. See *Hernia.*

Inguinal ligament. See *Poupart's ligament.*

INHUMATION. (From *inhumo*, to put into the ground.) The burying a patient in warm or medicated earth. Some chemists have fancied thus to call that kind of digestion which is performed by burying the materials in dung, or in the earth.

I'nion. (From ἴς, a nerve; as being the place where nerves originate.) The occiput. Blancard says it is the beginning of the spinal marrow; others say it is the back part of the neck.

Injacula'tio. (From *injaculor*, to shoot into.) So Helmont calls a disorder which consists of a violent spasmodic pain in the stomach, and an immobility of the body.

INJE'CTION. (*Injectio*; from *injicio*, to cast into.) A medicated liquor to throw into a natural or preternatural cavity of the body by means of a syringe.

INNOMINA'TUS. (From *in*, priv. and *nomen*, a name.) Some parts of the body are so named: thus, the pelvic bones, which in the young subject are three in number, to which names were given, become one in the adult, which was without a name; an artery from the arch of the aorta, and the fifth pair of nerves, because they appeared to have been forgotten by the older anatomists.

Innominata arteria. The first branch given off by the arch of the aorta. It soon divides into the right carotid and right subclavian arteries.

Innominati nervi. The fifth pair of nerves. See *Trigemini.*

Innominatum os. So called because the three bones of which it originally was formed grew together, and formed one complete bone, which was then left nameless. A large irregular bone, situated at the side of the pelvis. It is divided into three portions, viz. the iliac, ischiatic, and pubic, which are usually described as three distinct bones.

The *os ilium*, or haunch-bone, is of a very irregular shape. The lower part of it is thick and narrow; its superior portion is broad and thin, terminating in a ridge, called the *spine* of the ilium, and more commonly known by the name of the *haunch.* The spine rises up like an arch, being turned somewhat outward, and from this appearance, the upper part of the pelvis, when viewed together, has not been improperly compared to the wings of a phæton. This spine, in the recent subject, appears as if tipped with cartilage; but this appearance is nothing more than the tendinous fibres of the muscles that are inserted into it. Externally, this bone is unequally prominent, and hollowed for the attachment of muscles; and internally, at its broadest fore-part, it is smooth and concave. At its lower part, there is a considerable ridge on its inner surface. This ridge, which extends from the os sacrum, and corresponds with a similar prominence, both on that bone and the ischium, forms, with the inner part of the ossa pubis, what is called the brim of the pelvis. The whole of the internal surface, behind this ridge, is very unequal. The os ilium has likewise a smaller surface posteriorly, by which it is articulated to the sides of the os sacrum. This surface has, by some, been compared to the human ear, and, by others, to the head of a bird; but neither of these comparisons seem to convey any just idea of its form or appearance. Its upper part is rough and porous; lower down it is more solid. It is firmly united to the os sacrum by a cartilaginous substance, and likewise by very strong ligamentous fibres, which are extended to that bone from the whole circumference of this irregular surface. The spine of this bone, which is originally an epiphysis, has two considerable tuberosities, one anteriorly, and the other posteriorly, which is the largest of the two. The ends of this spine, too, from their projecting more than the parts of the bone below them, are called spinal processes. Before the anterior spinal process, the spine is hollowed, where part of the Sartorius muscle is placed; and below the posterior spinal process, there is a very large niche in the bone, which, in the recent subject, has a strong ligament stretched over its lower part, from the os sacrum to the sharp-pointed process of the ischium; so that a great hole is formed, through which pass the great sciatic nerve and the posterior crural vessels under the pyriform muscle, part of which is likewise lodged in this hole. The lowest, thickest, and narrowest part of the ilium, in conjunction with the other two portions of each os innominatum, helps to form the acetabulum for the os femoris.

The *os ischium*, or hip-bone, which is the lowest of the three portions of each os innominatum, is of a very irregular figure, and usually divided into its body, tuberosity, and ramus. The body externally forms the inferior portion of the acetabulum, and sends a sharp-pointed process backward, called the spine of the ischium. This is the process to which the ligament is attached, which was just now described as forming a great foramen for the passage of the sciatic nerve. The tuberosity is large and irregular, and is placed at the inferior part of the bone, giving origin to several muscles. In the recent subject, it seems covered with a cartilaginous crust; but this appearance, as in the spine of the ilium, is nothing more than the tendinous fibres of the muscles that are inserted into it. This tuberosity, which is the lowest portion of the trunk, supports us when we sit. Between the spine and the tuberosity is observed a sinuosity, covered with a cartilaginous crust, which serves as a pulley, on which the obturator muscle plays. From the tuberosity, the bone becoming narrower and thinner, forms the ramus, or branch, which passing forwards and upwards, makes, with the ramus of the os pubis, a large hole, of an oval shape, the *foramen magnum ischii*, which affords, through its whole circumference, attachment to muscles. This foramen is more particularly noticed in describing the os pubis.

The *os pubis*, or share-bone, which is the smallest of the three portions of the os innominatum, is placed at the upper and fore-part of the pelvis, where the two ossa pubis meet, and are united to each other by means of a very strong cartilage, which constitutes what is called the *symphysis pubis*. Each os pubis may be divided into its body, angle, and ramus. The body, which is the outer part, is joined to the os ilium. The angle comes forward to form the symphisis, and the ramus is a thin apophysis, which, uniting with the ramus of the ischium, forms the *foramen magnum ischii*, or *thyroideum*, as it has been sometimes called, from its resemblance to a door or shield. This foramen is somewhat wider above than below, and its greatest diameter is from above downwards, and obliquely from within outwards. In the recent subject, it is almost completely closed by a strong fibrous membrane called the *obturator* ligament. Upwards and outwards, where we observe a niche in the bone, the fibres of this ligament are separated, to allow a passage to the posterior crural nerve, an artery and vein. The great uses of this foramen seem to be to lighten the bones of the pelvis, and to afford a convenient lodgement to the obturator muscles. The three bones now described as constituting the os innominatum on each side, all concur to form the great *acetabulum*, or cotyloid cavity, which receives the head of the thigh-bone; the os ilium and os ischium making each about two-fifths, and the os pubis one-fifth, of the cavity. This acetabulum which is of considerable depth, is of a spherical shape. Its brims are high, and in the recent subject, it is tipped with cartilage. These brims, however, are higher above and externally than they are internally and below, where we observe a niche in the bone (namely the ischium,) across which is stretched a ligament, forming a hole for the transmission of blood-vessels and nerves to the cavity of the joint. The cartilage which lines the acetabulum, is thickest at its circumference, and thinner within, where a little hole is to be observed, in which is placed the apparatus that serves to lubricate the joint, and facilitate its motions. We are likewise able to discover the impression made by the internal ligament of the os femoris, which, by being attached both to this cavity and to the head of the os femoris, helps to secure the latter in the acetabulum. The bones of the pelvis serve to support the spine and upper parts of the body, to lodge the intestines, urinary bladder, and other viscera; and likewise to unite the trunk to the lower extremities. But, besides these uses, they are destined, in the female subject, for other important purposes; and the accoucheur finds, in the study of these bones, the foundation of all midwifery knowledge. Several eminent writers are of opinion, that in difficult parturition, all the bones of the pelvis undergo a certain degree of separation. It has been observed likewise, that the cartilage uniting the ossa pubis is thicker, and of a more spongy texture, in women than in men, and therefore more likely to swell and enlarge during pregnancy. That many instances of a partial separation of these bones during labour, have happened, there can be no doubt; such a separation, however, ought by no means to be considered as an uniform and salutary work of nature, as some writers seem to think, but as the effect of disease. But there is another circumstance in regard to this part of osteology, which is well worthy of attention; and this is, the different capacities of the pelvis in the male and female subject. It has been observed that the os sacrum is shorter and broader in women than in men; the ossa ilia are also found more expanded; whence it happens, that in women the centre of gravity does not fall so directly on the upper part of the thigh as in men, and this seems to be the reason why, in general, they step with less firmness, and move their hips forward in walking. From these circumstances also, the brim of the female pelvis is nearly of an oval shape, being considerably wider from side to side, than from the symphysis pubis to the os sacrum; whereas, in men, it is rounder, and every where of less diameter. The inferior opening of the pelvis is likewise proportionably larger in the female subject, the ossa ischia being more separated from each other, and the foramen ischii larger, so that, where the os ischium and os pubis are united together, they form a greater circle; the os sacrum is also more hollowed, though shorter, and the os coccygis more loosely connected, and, therefore, capable of a greater degree of motion than in men.

INOCULATION. *Inoculatio.* The insertion of a poison into any part of the body. It was mostly practised with that of the small-pox, because we had learnt, from experience, that by so doing, we generally procured fewer pustules, and a much milder disease, than when the small-pox was taken in a natural way. Although the advantages were evident, yet objections were raised against inoculation, on the notion that it exposed the person to some risk, when he might have passed through life, without ever taking the disease naturally; but it is obvious that he was exposed to much greater danger, from the intercourse which he must have with his fellow-creatures, by taking the disorder in a natural way. It has also been adduced, that a person is liable to take the small-pox a second time, when produced at first by artificial means; but such instances are very rare, besides not being sufficently authentic. We may conjecture that, in most of those cases, the matter used was not variolous, but that of some other eruptive disorder, such as the chicken-pox, which has often been mistaken for the small-pox. However, since the discovery of the preventive power of the cow-pock, small-pox inoculation has been rapidly falling into disuse. See *Variola vaccina.*

To illustrate the benefits arising from inoculation, it has been calculated that a third of the adults die who take the disease in a natural way, and about one-seventh of the children; whereas of those who are inoculated, and are properly treated afterwards, the proportion is probably not greater than one in five or six hundred.

Inoculation is generally thought to have been introduced into Britain from Turkey, by Lady Mary Wortley Montague, about the year 1721, whose son had been inoculated at Constantinople, during her residence there, and whose infant daughter was the first that underwent the operation in this country. It appears, however, to have been well known before this period, both in the south of Wales and Highlands of Scotland. Mungo Park, in his travels into the interior of Africa found that inoculation had been long practised by the Negroes on the Guinea coast; and nearly in the same manner, and at the same time of life, as in Europe. It is not clearly ascertained where inoculation really originated. It has been ascribed to the Circassians, who employed it as the means of preserving the beauty of their women. It appears more probable that accident first suggested the expedient among different nations, to whom the small-pox had long been known, independently of any intercourse with each other; and what adds to the probability of this conjecture is, that in most places where inoculation can be traced back, for a considerable length of time, it seems to have been practised chiefly by old women, before it was adopted by regular practitioners.

Many physicians held inoculation in the greatest contempt at first, from its supposed origin, others again discredited the fact of its utility: while others, on the testimony of the success in distant countries, believed in the advantages it afforded, but still did not think themselves warranted to recommend it to the families they attended; and it was not until the experiment of it had been made on six criminals (all of whom recovered from the disease and regained their liberty,) that it was practised, in the year 1726, on the royal family, and afterwards adopted as a general thing.

To insure success from inoculation, the following precautions should strictly be attended to.

1. That the person should be of a good habit of body, and free from any disease, apparent or latent, in order that he may not have the disease and a bad constitution, or perhaps another disorder, to struggle with at the same time.

2. To enjoin a temperate diet and proper regimen; and, where the body is plethoric, or gross, to make use of gentle purges, together with mercurial and antimonial medicines.

3. That the age of the person be as little advanced as possible, but not younger if it can be avoided, than four months.

4. To choose a cool season of the year, and to avoid external heat, either by exposure to the sun, sitting by fires, or in warm chambers, or by going too warmly clothed, or being too much in bed.

5. To take the matter from a young subject, who has the small-pox in a favourable way, and who is otherwise healthy, and free from disease; and, when fresh matter can be procured, to give it the preference.

Where matter of a benign kind cannot be procured, and the patient is evidently in danger of the casual small-pox, we should not however, hesitate a moment to inoculate from any kind of matter that can be procured; as what has been taken in malignant kinds of small-pox has been found to produce a very mild disease. The mildness or malignity of the disease appears, therefore, to depend little or not at all on the inoculating matter. Variolous matter, as well as the vaccine, by being kept for a length of time, particularly in a warm place, is apt, however, to undergo decomposition, by putrefaction; and then another kind of contagious material has been produced.

In inoculating, the operator is to make the slightest puncture or scratch imaginable in the arm of the person, rubbing that part of the lancet which is besmeared with matter repeatedly over it, by way of insuring the absorption; and in order to prevent its being wiped off, the shirt sleeve ought not to be pulled down until the part is dry.

A singular circumstance attending inoculation is, that when this fails in producing the disease, the inoculated part nevertheless sometimes inflames and suppurates, as in cases where the complaint is about to follow; and the matter produced in those cases, is as fit for inoculation as that taken from a person actually labouring under the disease. The same happens very frequently in inoculation for the cow-pox.

If, on the fourth or fifth day after the operation, no redness or inflammation is apparent on the edge of the wound, we ought then to inoculate in the other arm, in the same manner as before; or, for greater certainty, we may do it in both.

Some constitutions are incapable of having the disease in any form. Others do not receive the disease at one time, however freely exposed to its contagion, even though repeatedly inoculated, and yet receive it afterwards by merely approaching those labouring under it.

On the coming on of the febrile symptoms, which is generally on the seventh day in the inoculated small-pox, the patient is not to be suffered to lie a-bed, but should be kept cool, and partake freely of antiseptic cooling drinks. See *Variola.*

INOSCULA'TION. (*Inosculatio;* from *in,* and *osculum,* a little mouth.) The running of the veins and arteries into one another, or the interunion of the extremities of the arteries and veins.

INSA'NIA. (From *in,* not, and *sanus,* sound.) Insanity, or deranged intellect. A genus of disease in the class *Neuroses,* and order *Vesaniæ,* characterised by erroneous judgment, from imaginary perceptions or recollections, attended with agreeable emotions in persons of a sanguine temperament. See *Mania.*

Inse'ssus. (From *insideo,* to sit upon.) A hot-bath, simple or medicated, over which the patient sits.

Insipie'ntia. (From *in,* and *sapientia,* wisdom.) A delirium without fever.

Insola'tio. (From *in,* upon, and *sol,* the sun.) A disease which arises from a too great influence of the sun's heat upon the head, a coup de soleil.

INSPIRA'TION. (*Inspiratio;* from *in,* and *spiro,* to breathe.) The act of drawing the air into the lungs. See *Respiration.*

INSTINCT. (*Instinctus ûs.* m.) Animals are not abandoned by nature to themselves: they are all employed in a series of actions; whence results that marvellous whole that is seen among organized beings. To incline animals to the punctual execution of those actions which are necessary for them, nature has provided them with *instinct:* that is, propensities, inclinations, wants, by which they are constantly excited, and forced to fulfil the intentions of nature.

Instinct may excite in two different modes, with or without knowledge of the end. The first is enlightened instinct, the second is blind instinct; the one is particularly the gift of man, the other belongs to animals.

In examining carefully the numerous phenomena which depend on instinct, we see that there is a double design in every animal:—1. The preservation of the individual. 2. The preservation of the species. Every animal fulfils this end in its own way, and according to its organisation; there are therefore as many different instincts as there are different species; and as the organisation varies in individuals, instinct presents individual differences sometimes strongly marked.

We recognise two sorts of instinct in man: the one depends more evidently on his organisation, or his animal state; he presents it in whatever state he is found. This sort of instinct is nearly the same as that of animals. The other kind of instinct springs from the social state; and, without doubt, depends on organisation: what vital phenomenon does not depend on it? But it does not display itself except when man lives in civilised society, and when he enjoys all the advantages of that state.

To the first, that may be called animal instinct, belong hunger, thirst, the necessity of clothing, of a covering from the weather, the desire of agreeable sensations; the fear of pain and of death; the desire to injure others, if there is any danger to be feared from them, or any advantage to arise from hurting them; the venereal inclinations; the interest inspired by children; inclination to imitation; to live in society, which leads man to pass through the different degrees of civilisation, &c. These different instinctive feelings incline him to concur in the established order of organised beings. Man is, of all the animals, the one whose natural wants are most numerous, and of the greatest variety; which is in proportion to the extent of his intelligence; if he had only these wants, he would have always a marked superiority over the animals.

When man, living in society, can easily provide for all the wants which we have mentioned, he has then time, and powers of action more than his original wants require; then new wants arise, that may be called social wants: such is that of a lively perception of existence; a want which, the more it is satisfied, the more difficult it becomes, because the sensations become blunted by habit.

This want of a vivid existence, added to the continually increasing feebleness of the sensations, causes a mechanical restlessness, vague desires, excited by the remembrance of vivid sensations formerly felt: in order to escape from this state, man is continually forced to change his object, or to overstrain sensations of the same kind. Thence arises an inconstancy which never permits our desires to rest, and a progression of desires, which always annihilated by enjoyment, and irritated by remembrance, proceed forward without end; thence arises *ennui,* by which the civilised idler is incessantly tormented.

The want of vivid sensations is balanced by the love of repose and idleness in the opulent classes of society. These contradictory feelings modify each other, and from their reciprocal re-action results the love of power, of consideration, of fortune, &c. which give us the means of satisfying both.

These two instinctive sensations are not the only ones which spring from the social state; a crowd of others arise from it, equally real, though less important; besides, the natural wants become so changed as no longer to be known; hunger is often replaced by a capricious taste; the venereal desires by a feeling of quite another nature, &c.

The natural wants have a considerable influence upon those which arise from society; these, in their turn, modify the former; and if we add age, temperament, sex, &c. which tend to change every sort of want, we will have an idea of the difficulty which the study of the instinct of man presents. This part of physiology is also scarcely begun. We remark, however, that the social wants necessarily carry along with them the enlargement of the understanding; there is no comparison in regard to the capacity of the mind, between a man in the higher class of society, and a man whose physical powers are scarcely sufficient to provide for his natural wants.

INTEGER. When applied to leaves, perianths, petals, &c. *folia integra,* means undivided; and is said of the simple leaves, as those of the orchises and grasses. The female flower of the oak affords an example of the *perianthium integrum,* and the petals of the *Nigella arvensis* and *Silene quinquevulnera* are described as *petala integra.*

INTEGERRIMUS. Most perfect or entire. Applied to leaves, the margin of which has no teeth, notches, or incisions. It regards solely the margin; whereas the *folium integrum* respects the whole shape, and has nothing to do with the margin.

INTERCO′STAL. (*Intercostalis*; from *inter*, between, and *costa*, a rib.) A name given to muscles, vessels, &c. which are between the ribs.

INTERCOSTAL ARTERIES. *Arteriæ intercostales.* The arteries which run between the ribs. The superior intercostal artery is a branch of the subclavian. The other intercostal arteries are given off from the aorta.

INTERCOSTAL MUSCLES. *Intercostales externi et interni.* Between the ribs on each side are eleven double rows of muscles. These are the *intercostales externi*, and *interni*. Galen has very properly observed, that they decussate each other like the strokes of the letter X. The *intercostales externi* arise from the lower edge of each superior rib, and, running obliquely downwards and forwards, are inserted into the upper edge of each inferior rib, so as to occupy the intervals of the ribs, from as far back as the spine to their cartilages; but from their cartilages to the sternum, there is only a thin aponeurosis covering the internal intercostales. The *intercostales interni* arise and are inserted in the same manner as the external. They begin at the sternum, and extend as far as the angles of the ribs, their fibres running obliquely backwards. These fibres are spread over a considerable part of the inner surface of the ribs, so as to be longer than those of the external intercostals. Some of the posterior portions of the internal intercostals pass over one rib, and are inserted into the rib below. Verheyen first described these portions as separate muscles, under the name of *infra costales*. Winslow has adopted the same name. Cowper, and after him Douglas, call them *costarum depressores proprii.* These distinctions, however, are altogether superfluous, as they are evidently nothing more than appendages of the intercostals. The number of these portions varies in different subjects. Most commonly there are only four, the first of which runs from the second rib to the fourth, the second from the third rib to the fifth, the third from the fourth rib to the sixth, and the fourth from the fifth rib to the seventh. The internal intercostals of the two inferior false ribs are frequently so thin, as to be with difficulty separated from the external; and, in some subjects, one or both of them seem to be altogether wanting. It was the opinion of the ancients, that the external intercostals serve to elevate, and the internal to depress the ribs. They were probably led to this opinion, by observing the different direction of their fibres; but it is now well known, that both have the same use, which is that of raising the ribs equally during inspiration. Fallopius was one of the first who ventured to call in question the opinion of Galen on this subject, by contending that both layers of the intercostals serve to elevate the ribs. In this opinion he was followed by Hieronymus Fabricius, our countryman Mayow, and Borelli. But, towards the close of the last century, Bayle, a writer of some eminence, and professor at Toulouse, revived the opinion of the ancients by the following arguments:—He observed, that the oblique direction of the fibres of the internal intercostals is such, that in each inferior rib, these fibres are nearer to the vertebræ than they are at their superior extremities, or in the rib immediately above; and that, of course, they must serve to draw the rib downwards, as towards the most fixed point. This plausible doctrine was adopted by several eminent writers, and among others, by Nicholls, Hoadley, and Schreiber; but above all, by Hamberger, who went so far as to assert, that not only the ribs, but even the sternum are pulled downwards by these muscles, and constructed a particular instrument to illustrate this doctrine. He pretended likewise that the intervals of the ribs are increased by their elevation, and diminished by their depression; but he allowed that, while those parts of the internal intercostals that are placed between the bony part of the ribs pull them downwards, the anterior portions of the muscle, which are situated between the cartilages, concur with the external intercostals in raising them upwards. These opinions gave rise to a warm and interesting controversy, in which Hamberger and Haller were the principal disputants. The former argued chiefly from theory, and the latter from experiments on living animals, which demonstrate the fallacy of Hamberger's arguments, and prove beyond a doubt, that the internal intercostals perform the same functions as the external.

INTERCOSTAL NERVE. *Nervus intercostalis.* Great intercostal nerve. Sympathetic nerve. The great intercostal nerve arises in the cavity of the cranium, from a branch of the sixth and one of the fifth pair, uniting into one trunk, which passes out of the cranium through the carotid canal, and descends by the sides of the bodies of the vertebræ of the neck, thorax, loins, and os sacrum: in its course, it receives the small accessory branches from all the thirty pair of spinal nerves. In the neck, it gives off three cervical ganglions, the upper, middle, and lower; from which the cardiac and pulmonary nerves arise. In the thorax, it gives off the splanchnic or anterior intercostal, which perforates the diaphragm, and forms the semilunar ganglions, from which nerves pass to all the abdominal viscera. They also form in the abdomen ten peculiar plexuses, distinguished by the name of the viscus, to which they belong, as the cœliac, splenic, hepatic, superior, middle, and lower, mesenteric, two renal, and two spermatic plexuses. The posterior intercostal nerve gives accessory branches about the pelvis and ischiatic nerve, and at length terminates.

INTERCOSTAL VEINS. The intercostal veins empty their blood into the vena azygos.

INTERCU′RRENT. Those fevers which happen in certain seasons only, are called stationary: others are called, by Sydenham intercurrents.

INTE′RCUS. (From *inter*, between, and *cutis*, the skin.) A dropsy between the skin and the flesh. See *Anasarca.*

INTERDE′NTIUM. (From *inter*, between, and *dens*, a tooth.) The intervals between teeth of the same order.

INTERDI′GITUM. (From *inter*, between, and *digitus*, a toe, or finger.) A corn betwixt the toes, or wart betwixt the fingers.

INTERFÆMI′NEUM. (From *inter*, between, and *fæmen*, the thigh.) The perinæum, or space between the anus and pudendum.

INTERLU′NIUS. (From *inter*, between, and *luna*, the moon; because it was supposed to affect those who were born in the wane of the moon.) The epilepsy.

Intermediate affinity. See *Affinity intermediate.*

INTERMITTENT. (*Intermittens*; from *inter*, between, and *mitto*, to send away.) A disease is so called which does not continue until it finishes one way or the other, as most diseases do, but ceases and returns again at regular or uncertain periods; as agues, &c.

Intermittent fever. See *Febris intermittens.*

INTERNODIS. Applied to a flower-stalk or pedunculus, when it proceeds from the intermediate part of a branch between two leaves; as in *Ehretia internodis.*

INTERNU'NTII DIES. (From *internuncio*, to go between.) Applied to critical days, or such as stand between the increase of a disorder and its decrease.

INTERO'SSEI MANUS. (*Interosseus;* from *inter*, between, and *os*, the bone.) These are small muscles situated between the metacarpal bones, and extending from the bones of the carpus to the fingers. They are divided into *internal* and *external;* the former are to be seen only on the palm of the hand, but the latter are conspicuous both on the palm and back of the hand. The *interossei interni* are three in number. The first, which Albinus names *posterior indicis*, arises tendinous and fleshy from the basis and inner part of the metacarpal bone of the fore-finger, and likewise from the upper part of that which supports the middle finger. Its tendon passes over the articulation of this part of these bones with the fore-finger, and, uniting with the tendinous expansion that is sent off from the extensor digitorum communis, is inserted into the posterior convex surface of the first phalanx of that finger. The second and third, to which Albinus gives the names of *prior annularis*, and *interrosseus auricularis*, arise, in the same manner, from the basis of the outsides of the metacarpal bones that sustain the ring-finger and the little finger, and are inserted into the outside of the tendinous expansion of the extensor digitorum communis that covers each of those fingers. These three muscles draw the fingers into which they are inserted, towards the thumb. The *interossei externi* are four in number; for among these is included the small muscle that is situated on the outside of the metacarpal bone that supports the fore-finger. Douglas calls it *extensor tertii internodii indicis*, and Winslow *semi interosseus indicis.* Albinus, who describes it among the interossei, gives it the name of *prior indicis.* This first interosseus externus arises by two tendinous and fleshy portions. One of these springs from the upper half of the inner side of the first bone of the thumb, and the other from the ligaments that unite the os trapezoides to the metacarpal bone of the fore-finger, and likewise from all the outside of this latter bone. These two portions unite as they descend, and terminate in a tendon, which is inserted into the outside of that part of the tendinous expansion from the extensor digitorum communis that is spread over the posterior convex surface of the fore-finger. The second, to which Albinus gives the name of *prior medii*, is not quite so thick as the last-described muscle. It arises by two heads, one of which springs from the inner side of the metacarpal bone of the fore-finger, chiefly towards its convex surface, and the other arises from the adjacent ligaments, and from the whole outer side of the metacarpal bone that sustains the middle finger. These two portions unite as they descend, and terminate in a tendon, which is inserted, in the same manner, as the preceding muscle, into the outside of the tendinous expansion that covers the posterior part of the middle finger. The third belongs likewise to the middle-finger, and is therefore named *posterior medii* by Albinus. It arises, like the last-described muscle, by two origins, which spring from the roots of the metacarpal bones of the ring and middle-fingers, and from the adjacent ligaments, and is inserted into the inside of the same tendinous expansion as the preceding muscle. The fourth, to which Albinus gives the name of *posterior annularis*, differs from the two last only in its situation, which is between the metacarpal bones of the ring and little fingers. It is inserted into the inside of the tendinous expansion of the extensor digitorum communis, that covers the posterior part of the ring-finger. All these four muscles serve to extend the fingers into which they are inserted, and likewise to draw them inwards, towards the thumb, except the third, or *posterii medii*, which, from its situation and insertion, is calculated to pull the middle finger outwards.

INTEROSSEI PEDIS. These small muscles, in their situation between the metatarsal bones, resemble the interossei of the hand, and like them, are divided into *internal* and *external.* The *interossei pedis interni* are three in number. They arise tendinous and fleshy, from the basis and inside of the metatarsal bones of the middle, the third, and the little toes, in the same manner as those of the hand, and they each terminate in a tendon that runs to the inside of the first joint of these toes, and from thence to their upper surface, where it loses itself in the tendinous expansion that is sent off from the extensors. Each of these three muscles serves to draw the toe into which it is inserted towards the great toe. The *interossei externi* are four in number. The first arises tendinous and fleshy from the outside of the root of the metatarsal bone of the great toe, from the os cuneiforme internum, and from the root of the inside of the metatarsal bone of the fore-toe. Its tendon is inserted into the inside of the tendinous expansion that covers the back part of the toes. The second is placed in a similar manner between the metatarsal bones of the fore and middle toes, and is inserted into the outside of the tendinous expansion on the back part of the fore-toe. The third and fourth are placed between the two next metatarsal bones, and are inserted into the outside of the middle and third toes. The first of these muscles draws the fore-toe inwards towards the great toe. The three others pull the toes, into which they are inserted, outwards. They all assist in extending the toes.

INTEROSSEOUS. (*Interosseus;* from *inter*, between, and *os*, a bone.) A name given to muscles, ligaments, &c. which are between bones.

INTERPELLA'TUS. (From *interpello*, to interrupt.) A name given by Paracelsus to a disease attended with irregular or uncertain paroxysms.

INTERPOLA'TUS DIES. (From *interpolo*, to renew.) In Paracelsus, these are the days interpolated betwixt two paroxysms.

INTERSCAPU'LIUM. (From *inter*, between, and *scapula*, the shoulder-blade.) That part of the spine which lies between the shoulders.

INTERSE'PTUM. (From *inter*, between, and *septum*, an inclosure.) The uvula and the septum narium.

INTERSPINA'LIS. (From *inter*, between, and *spina*, the spine.) Muscles, nerves, &c. are so named which are between the processes of the spine.

INTERSPINALES. The fleshy portions between the spinous processes of the neck, back, and loins, distinguished by the names of *interspinales colli, dorsi et lumborum.* Those which connect processes of the back and loins, are rather small tendons than muscles: they draw these processes nearer to each other.

INTERTRANSVERSA'LES. Four distinct small bundles of flesh, which fill up the spaces between the transverse processes of the vertebræ of the loins, and serve to draw them towards each other.

INTERTRI′GO. (From *inter*, between, and *tero*, to rub.) An excoriation about the anus, groins, axilla, or other parts of the body, attended with inflammation and moisture. It is most commonly produced by the irritation of the urine, from riding, or some acrimony in children.

INTE′STINE. (*Intestinum*; from *intus*, within.) The convoluted membraneous tube that extends from the stomach to the anus, receives the ingested food, retains it a certain time, mixes with it the bile and pancreatic juice, propels the chyle into the lacteals, and covers the fæces with mucus, is so called. The intestines are situated in the cavity of the abdomen, and are divided into the small and large, which have, besides their size, other circumstances of distinction.

The *small* intestines are supplied internally with folds, called *valvulæ conniventes*, and have no bands on their external surface. The *large* intestines have no folds internally; are supplied externally with three strong muscular bands, which run parallel upon the surface, and give the intestines a saccated appearance; they have also small fatty appendages, called *appendiculæ epiploicæ*.

The first portion of the intestinal tube, for about the extent of twelve fingers' breadth, is called the *duodenum*; it lies in the epigastric region; makes three turnings, and between the first and second flexure receives, by a common opening, the pancreatic duct, and the ductus communis choledochus. It is in this portion of the intestines that chylification is chiefly performed. The remaining portion of the small intestines is distinguished by an imaginary division into the jejunum and ileum.

The *jejunum*, which commences where the duodenum ends, is situated in the umbilical region, and is mostly found empty; hence its name: it is every where covered with red vessels, and, about an hour and a half after a meal, with distended lacteals.

The *ileum* occupies the hypogastric region and the pelvis; is of a more pallid colour than the former, and terminates by a transverse opening into the large intestines, which is called the *valve of the ileum, valve of the cæcum, or the valve of Tulpius.*

The beginning of the large intestines is firmly tied down in the right iliac region, and for the extent of about four fingers' breadth is called the *cæcum*, having adhering to it a worm-like process, called the *processus cæci, vermiformis*, or *appendicula cæci vermiformis*. The great intestine then commences *colon*, ascends towards the liver, passes across the abdomen, under the stomach, to the left side, where it is contorted like the letter *S*, and descends to the pelvis: hence it is divided in this course into the *ascending portion*, *the transverse arch*, and the *sigmoid flexure*. When it has reached the pelvis, it is called the *rectum*, from whence it proceeds in a straight line to the anus.

The intestinal canal is composed of three membranes, or coats; a *common* one from the peritoneum, a *muscular coat*, and a *villous coat*, the villi being formed of the fine terminations of arteries and nerves, and the origins of lacteals and lymphatics. The intestines are connected to the body by the mysentery; the duodenum has also a peculiar connecting cellular substance, as have likewise the colon and rectum, by whose means the former is firmly accreted to the back, the colon to the kidneys, and the latter to the os coccygis, and, in women, to the vagina. The remaining portion of the tube is loose in the cavity of the abdomen. The arteries of this canal are branches of the *superior* and *inferior mesenteric*, and the *duodenal*. The veins evacuate their blood into the vena portæ. The nerves are branches of the eight pair and intercostals. The *lacteal vessels*, which originate principally from the jejunum, proceed to the glands in the mesentery.

INTRAFOLIACEUS. Applied to stipulæ, which are above the footstalk, and internal with respect to the leaf; as in *Ficus carica*, and *Morus nigra.*

Intrica′tus. (From *intrico*, to entangle; so called from its intricate folds.) A muscle of the ear.

Intri′nsecus. (From *intra*, within, and *secus*, towards.) A painful disorder of an internal part.

Introce′ssio. (From *introcedo*, to go in.) *Depressio.* A depression or sinking of any part inwards.

INTUS-SUSCE′PTION. (*Intus-susceptio* and *intro-susceptio*; from *intus*, within, and *suscipio*, to receive.) A disease of the intestinal tube, and most frequently of the small intestines; it consists in a portion of gut passing for some length within another portion.

I′NTYBUS. (From *in*, and *tuba*, a hollow instrument: so named from the hollowness of its stalk.) See *Cichorium endivia.*

I′NULA. (Contracted or corrupted from *helenium*, ηλενιον, fabled to have sprung from the tears of Helen.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia superflua.*

2. The herb *inula*, or elecampane. See *Inula helenium.*

Inula, common. See *Inula helenium.*

Inula crithmoides. *Caaponga* of the Brazilians. *Trifolia spica*; *Crithmum marinum non spinosum.* The leaves and young stalks of this plant are pickled for the use of the table; they are gently diuretic.

Inula dysenterica. The systematic name of the lesser inula, *Conyza media. Arnica Suedensis, Arnica spurio, Conyza: Inula—amplexicaulibus, cordato oblongis; caule villoso, paniculato; squamis calycinis, setaceis* of Linnæus. This indigienous plant was once considered as possessing great antidysenteric virtues. The whole herb is to the taste acrid, and at the same time rather aromatic. It is now fallen into disuse.

Inula helenium. The systematic name of the common inula or elecampane. *Enula campana; Helenium. Inula—foliis amplexicaulibus ovatis rugosis subtus tomentosis, calycum squamis ovatis*, of Linnæus. This plant, though a native of Britain, is seldom met with in its wild state, but mostly cultivated. The root which is the part employed medicinally, in its recent state, has a weaker and less grateful smell than when thoroughly dried; and kept for a length of time, by which it is greatly improved, its odour then approaching to that of Florentine orris root. It was formerly in high estimation in dyspepsia, pulmonary affections, and uterine obstructions, but is now fallen into disuse. From the root of this plant, Rose first extracted the peculiar vegetable principle called *inulin*. Funke has since given the following as the analysis of elecampane root:—A crystallisable volatile oil; inulin; extractive; acetic acid; a crystallisable resin; gluten; a fibrous matter. See *Inulin.*

INULIN. In examining the *Inula helenium*, by *Elecampane*, Rose imagined he discovered a new vegetable product, to which the name of *Inulin* has been given. It is white and pulverulent like starch. When thrown on red-hot coals, it melts, diffusing a white smoke, with the smell of burning sugar. It yields, on distillation in a retort, all the products furnished by gum. It dissolves readily in hot water; and precipitates almost entirely on cooling, in the form of a white powder; but before falling down, it gives the liquid a mucilaginous consistence. It precipitates quickly on the addition of alkohol.

The above substance is obtained by boiling the root of this plant in four times its weight of water, and leaving the liquid in repose. Pelletier and Caventou have found the same starch-like matter in abundance in the root of colchicum; and Gautier in the root of pellitory.

INUSTION. (From *in*, and *uro*, to burn.) It is sometimes used for hot and dry seasons; and formerly by surgeons for the operation of the cautery.

INVERECU'NDUM OS. (From *in*, not, and *verecundus*, modest.) An obsolete name of the frontal bones, from its being regarded as the seat of impudence.

INVERSION. *Inversio.* Turned inside outward.

INVOLUCELLUM. A partial involucrum. See *Involucrum*.

INVOLU'CRUM. (From *in*, and *volvo*, to wrap up; because parts are enclosed by it.) In anatomy. 1. A name of the pericardium.

2. A membrane which covers any part.

In botany. A leafy calyx, remote from the flower, applied particularly to umbelliferous plants.

From the part of the umbel in which it is placed, it is called,

1. *Involucrum universale*, being at the base of the whole umbel; as in *Coriandrum sativum*, *Scandix cerefolium*, and *Cornus mascula*.
2. I. *partiale*, called *involucellum;* at the bottom of each umbellula, or partial stalk of the umbel; as in *Daucus carota*.
3. I. *dimidiatum*, surrounding the middle of the stalk at the base of the umbel; as in *Æthusa cynapium*.

From the number of the involucre leaves,

4. *Monophyllous;* as in *Coriander* and *Hermas*.
5. *Triphyllous;* as in *Bupleurum junceum*.
6. *Polyphyllous;* as in *Bunium bulbocastanum*, and *Sium*.
7. *Pinnatifid;* as in *Daucus carota*, and *Sium angustifolium*.
8. *Reflex*, turned back; as in *Selinum monnieri*.

Solitary flowers rarely have an involucrum; yet it is found in the anemones.

INVOLUTUS. Involute. Rolled inwards. Applied to leaves, petals, &c. when their margins are turned inward; as in the leaves of *Pinguicula*, and petals of *Anethum*, *Pastinaca*, and *Bupleurum*.

IODATE. A compound of iodine with oxygen, and a metallic basis. The *oxiodes* of Davy.

IODES. (From ιος, verdigris.) Green matter thrown off by vomiting.

IODIC ACID. *Acidum iodicum.* Oxiodic acid. "When barytes water is made to act on iodine, a soluble hydriodate, and an insoluble iodate of barytes, are formed. On the latter, well washed, pour sulphuric acid equivalent to the barytes present, diluted with twice its weight of water, and heat the mixture. The iodic acid quickly abandons a portion of its base, and combines with the water; but though even less than the equivalent proportion of sulphuric acid has been used, a little of it will be found mixed with the liquid acid. If we endeavour to separate this portion, by adding barytes water, the two acids precipitate together.

The above economical process is that of Gay Lussac; but Sir H. Davy, who is the first discoverer of this acid, invented one more elegant, and which yields a purer acid. Into a long glass tube, bent like the letter L inverted (ᒣ), shut at one end, put 100 grains of chlorate of potassa, and pour over it 400 grains of muriatic acid, specific gravity 1.105. Put 40 grains of iodine into a thin long-necked receiver. Into the open end of the bent tube put some muriate of lime, and then connect it with the receiver. Apply a gentle heat to the sealed end of the former. Protoxide of chlorine is evolved, which, as it comes in contact with the iodine, produces combustion, and two new compounds, a compound of iodine and oxygen, and one of iodine and chlorine. The latter is easily separated by heat, while the former remains in a state of purity.

The iodic acid of Sir H. Davy is a white semitransparent solid. It has a strong acido-astringent taste, but no smell. Its density is considerably greater than that of sulphuric acid, in which it rapidly sinks. It melts, and is decomposed into iodine and oxygen, at a temperature of about 620°. A grain of iodic acid gives out 176.1 grain measure of oxygen gas. It would appear from this, that iodic acid consists of 15.5 iodine, to 5 oxygen.

Iodic acid deliquesces in the air, and is, of course, very soluble in water. It first reddens and then destroys the blues of vegetable infusions. It blanches other vegetable colours. Between the acid prepared by Gay Lussac, and that of Sir H. Davy, there is one important difference. The latter being dissolved, may, by evaporation of the water, pass not only to the inspissated syrup state, but can be made to assume a pasty consistence; and, finally, by a stronger heat, yields the solid substance unaltered. When a mixture of it, with charcoal, sulphur, resin, sugar, or the combustible metals, in a finely divided state, is heated, detonations are produced; and its solution rapidly corrodes all the metals to which Sir H. Davy exposed it, both gold and platinum, but much more intensely the first of these metals.

It appears to form combinations with all the fluid or solid acids which it does not decompose. When sulphuric acid is dropped into a concentrated solution of it in hot water, a solid substance is precipitated, which consists of the acid and the compound; for, on evaporating the solution by a gentle heat, nothing rises but water. On increasing the heat in an experiment of this kind, the solid substance formed fused; and on cooling the mixture, rhomboidal crystals formed of a pale yellow colour, which were very fusible, and which did not change at the heat at which the compound of oxygen and iodine decomposes, but sublimed unaltered. When urged by a much stronger heat, it partially sublimed, and partially decomposed, affording oxygen, iodine, and sulphuric acid.

With hydro-phosphoric, the compound presents phenomena precisely similar, and they form together a solid, yellow, crystalline combination.

With hydro-nitric acid, it yields white crystals in rhomboidal plates, which, at a lower heat than the preceding acid compounds, are resolved into hydro-nitric acid, oxygen, and iodine. By liquid muriatic acid, the substance is immediately decomposed, and the compound of chlorine and iodine is formed. All these acid compounds redden vegetable blues, taste sour, and dissolve gold and platinum. From these curious researches Sir H. Davy infers, that Gay Lussac's iodic acid, is a sulpho-iodic acid, and probably a definite compound. However minute the quantity of sulphuric acid made to act on the iodide of barium may be, a part of it is always employed to form the compound acid; and the residual fluid contains both the compound acid and a certain quantity of the original salt."—*Ure.*

IODIDE. *Iode; Iodure.* A compound of iodine with a metal; as *Iodide of potassium.*

IODINE. (*Iodina;* from ιώδης, a violet colour, so termed from its beautiful colour.) A peculiar or undecompounded principle.

"Iodine was accidentally discovered, in 1812, by De Courtois, a manufacturer of saltpetre at Paris. In his processes for procuring soda from the ashes of sea-weeds, he found the metallic vessels much corroded; and in searching for the cause of the corrosion, he made this important discovery. But for this circumstance, nearly accidental, one of the most curious of substances might have remained for ages unknown, since nature has not distributed it, in either a simple or compound state, through her different kingdoms, but has confined it to what the Roman satirist considers as the most worthless of things, the vile sea-weed.

Iodine derived its first illustration from Clement and Desormes. In their memoir, read at a meeting of the Institute, these able chemists described its principal properties. They stated its sp. gr. to be about 4; that it becomes a violet-coloured gas at a temperature below that of boiling water,—whence its name; that it combines with the metals, and with phosphorus and sulphur, and likewise with the alkalies and metallic oxides; that it forms a detonating compound with ammonia; that it is soluble in alkohol, and still more soluble in æther; and that by its action upon phosphorus, and upon hydrogen, a substance having the characters of muriatic acid is formed. In this communication they offered no decided opinion respecting its nature.

In 1813 Sir H. Davy happened to be on a visit to Paris, receiving, amid the political convulsions of France, the tranquil homage due to his genius. 'When Clement showed iodine to me,' says Sir H. Davy, 'he believed that the hydriodic acid was muriatic acid; and Gay Lussac, after his early experiments, made originally with Clement, formed the same opinion, and *maintained* it, when I *first* stated to him my belief, that it was a new and peculiar acid, and that iodine was a substance analogous in its chemical relations to chlorine.'

Iodine has been found in the following sea-weeds, the *Algæ aquaticæ* of Linnæus:—

Fucus cartilagineus,
membranaceus,
filamentosus,
rubens,
nodosus,
serratus,
siliquosus,

Fucus palmatus,
filum,
digitatus,
saccharinus,
Ulva umbilicalis,
pavonia,
linza, and in sponge.

It is from the incinerated sea-weed, or kelp, that iodine in quantities is to be obtained. Dr. Wollaston first communicated a precise formula for extracting it. Dissolve the soluble part of kelp in water. Concentrate the liquid by evaporation, and separate all the crystals that can be obtained. Pour the remaining liquid into a clean vessel, and mix with it an excess of sulphuric acid. Boil this liquid for some time. Sulphur is precipitated, and muriatic acid driven off. Decant off the clear liquid, and strain it through wool. Put it into a small flask, and mix it with as much black oxide of manganese as we used before of sulphuric acid. Apply to the top of the flask a glass tube, shut at one end. Then heat the mixture in the flask. The iodine sublimes in the glass tube. None can be obtained from sea-water.

Iodine is a solid, of a greyish-black colour and metallic lustre. It is often in scales similar to those of micaceous iron ore, sometimes in rhomboidal plates, very large and very brilliant. It has been obtained in elongated octohedrons, nearly half an inch in length; the axes of which were shown by Dr. Wollaston to be to each other, as the numbers 2, 3, and 4, at least so nearly, that in a body so volatile, it is scarcely possible to detect an error in this estimate, by the reflective goniometer. Its fracture is lamellated, and it is soft and friable to the touch. Its taste is very acrid, though it be very sparingly soluble in water. It is a deadly poison. It gives a deep brown stain to the skin, which soon vanishes by evaporation. In odour, and power of destroying vegetable colours, it resembles very dilute aqueous chlorine. The sp. gr. of iodine at 62½° is 4.948. It dissolves in 7000 parts of water. The solution is of an orange-yellow colour, and in small quantity tinges raw starch of a purple hue.

It melts, according to Gay Lussac, at 227° F., and is volatilised under the common pressure of the atmosphere, at the temperature of 350°. It evaporates pretty quickly at ordinary temperatures. Boiling water aids its sublimation, as is shown in the above process of extraction. The sp. gr. of its violet vapour is 8.678. It is a nonconductor of electricity. When the voltaic chain is interrupted by a small fragment of it, the decomposition of water instantly ceases.

Iodine is incombustible, but with azote it forms a curious detonating compound; and in combining with several bodies, the intensity of mutual action is such as to produce the phenomena of combustion. Its combinations with oxygen and chlorine are described, under iodic and chloriodic acids.

With a view of determining whether it was a simple or compound form of matter, Sir H. Davy exposed it to the action of the highly inflammable metals. When its vapour is passed over potassium heated in a glass tube, inflammation takes place, and the potassium burns slowly with a pale blue light. There was no gas disengaged when the experiment was repeated in a mercurial apparatus. The iodide of potassium is white, fusible at a red heat, and soluble in water. It has a peculiar acrid taste. When acted on by sulphuric acid, it effervesces, and iodine appears. It is evident that in this experiment there had been no decomposition; the result depending merely on the combination of iodine with potassium. By passing the vapour of iodide over dry red-hot potassa, formed from potassium, oxygen is expelled, and the above iodine results. Hence we see, that at the temperature of ignition, the affinity between iodine and potassium is superior to that of the latter for oxygen. But iodine in its turn is displaced by clorine, at a moderate heat, and if the latter be in excess, chloriodic acid is formed. Gay Lussac passed vapour of iodine in a red heat over melted subcarbonate of potassa; and he obtained carbonic acid and oxygen gases, in the proportions of two in volume of the first, and one of the second, precisely those which exist in the salt.

The oxide of sodium, and the subcarbonate of soda, are also completely decomposed by iodine.

From these experiments it would seem, that this substance ought to disengage oxygen from most of the oxides; but this happens only in a small number of cases. The protoxides of lead and bismuth are the only oxides, not reducible by mere heat, with which it exhibited that power. Barytes, strontian, and lime, combine with iodine, without giving out oxygen gas, and the oxides of zinc and iron undergo no alteration in this respect. From these facts we must conclude, that the decomposition of the oxides by iodine depends less on the condensed state of the oxygen, than upon the affinity of the metal for iodine. Except barytes, strontian, and lime, no oxide can remain in combination with iodine at a red heat. For a more particular account of some iodides, see *Hydriodic acid;* the compounds of which, in the liquid or moist state, are *hydriodates*, but change, on drying, into *iodides*, in the same way as the muriates become chlorides.

From the proportion of the constituents in hydriodic acid, 15.5 has been deduced as the prime equivalent of iodine.

Iodine forms with sulphur a feeble compound, of a greyish-black colour, radiated like sulphuret of antimony. When it is distilled with water, iodine separates.

Iodine and phosphorus combine with great rapidity at common temperatures, producing heat without light. From the presence of a little moisture, small quantities of hydriodic acid gas are exhaled.

Oxygen expels iodine from both sulphur and phosphorus.

Hydrogen, whether dry or moist, did not seem to have any action on iodine at the ordinary temperature; but if we expose a mixture of hydrogen and iodine to a red heat in a tube, they unite together, and hydriodic acid is produced, which gives a reddish brown colour to water. Sir H. Davy threw the violet-coloured gas upon the flame of hydrogen, when it seemed to support its combustion. He also formed a compound of iodine with hydrogen, by heating to redness the two bodies in a glass tube.

Charcoal has no action upon iodine, either at a high or low temperature. Several of the common metals, on the contrary, as zinc, iron, tin, mercury, attack it readily, even at a low temperature, provided they be in a divided state. Though these combinations take place rapidly, they produce but little heat, and but rarely any light.

The compound of iodine and zinc, or iodide of zinc, is white. It melts readily, and is sublimed in the state of fine acicular four-sided prisms. It is very soluble in water, and rapidly deliquesces in the air. It dissolves in water, without the evolution of any gas. The solution is slightly acid, and does not crystallise. The alkalies precipitate from it white oxide of zinc; while concentrated sulphuric acid disengages hydriodic acid and iodine, because sulphurous acid is produced. The solution is a hydriodate of oxide of zinc. When iodine and zinc are made to act on each other under water in vessels hermetically sealed, on the application of a slight heat, the water assumes a deep reddish-brown colour, because, as soon as hydriodic acid is produced, it dissolves iodine in abundance. But by degrees the zinc, supposed to be in excess, combines with the whole iodine, and the solution becomes colourless like water.

Iron is acted on by iodine in the same way as zinc; and a brown iodide results, which is fusible at a red heat. It dissolves in water, forming a light green solution, like that of muriate of iron. When the dry iodide was heated, by Sir H. Davy, in a small retort containing pure ammoniacal gas, it combined with the ammonia, and formed a compound which volatilised without leaving any oxide.

The iodide of tin is very fusible. When in powder, its colour is a dirty orange-yellow, not unlike that of glass of antimony. When put into a considerable quantity of water, it is completely decomposed. Hydriodic acid is formed, which remains in solution in the water, and the oxide of tin precipitates in white flocculi. If the quantity of water be small, the acid, being more concentrated, retains a portion of oxide of tin, and forms a silky orange-coloured salt, which may be almost entirely decomposed by water. Iodine and tin act very well on each other, in water of the temperature of 212°. By employing an excess of tin, we may obtain pure hydriodic acid, or at least an acid containing only traces of the metal. The tin must be in considerable quantity, because the oxide which precipitates on its surface, diminishes very much its action on iodine.

Antimony presents, with iodine, the same phenomena as tin; so that we might employ either for the preparation of hydriodic acid, if we were not acquainted with preferable methods.

The iodides of lead, copper, bismuth, silver, and mercury, are insoluble in water, while the iodides of the very oxidisable metals are soluble in that liquid. If we mix a hydriodate with the metallic solutions, all the metals which do not decompose water will give precipitates, while those which decompose that liquid will give none. This is at least the case with the above mentioned metals.

There are two iodides of mercury; the one yellow, the other red; both are fusible and volatile. The yellow or pro-tiodide, contains one-half less iodine than the deut-iodide. The latter, when crystallised, is a bright crimson. In general, there ought to be for each metal as many iodides as there are oxides and chlorides. All the iodides are decomposed by concentrated sulphuric and nitric acids. The metal is converted into an oxide, and iodine is disengaged. They are likewise decomposed by oxygen at a red heat, if we except the iodides of potassium, sodium, lead, and bismuth. Chlorine likewise separates iodine from all the iodides; but iodine, on the other hand, decomposes most of the sulphurets and phosphurets.

When iodine and oxides act upon each other in contact with water, very different results take place from those above described. The water is decomposed; its hydrogen unites with iodine, to form hydriodic acid; while its oxygen, on the other hand, produces with iodine, iodic acid. All the oxides, however, do not give the same results. We obtain them only with potassa, soda, barytes, strontian, lime, and magnesia. The oxide of zinc, precipitated by ammonia from its solution in sulphuric acid, and well washed, gives no trace of iodate and hydriodate.

From all the above recited facts, we are warranted in concluding iodine to be *an undecompounded body*. In its specific gravity, lustre, and magnitude of its prime equivalent, it resembles the metals; but in all its chemical agencies, it is analogous to oxygen and chlorine. It is a non-conductor of electricity, and possesses, like these two bodies, the negative electrical energy with regard to metals, inflammable and alkaline substances; and hence when combined with these substances in aqueous solution, and electrised in the voltaic circuit, it separates at the positive surface. But it has a positive energy with respect to chlorine: for when united to chlorine, in the chloriodic acid, it separates at the negative surface. This likewise corresponds with their relative attractive energy, since chlorine expels iodine from all its combinations. Iodine dissolves in carburet of sulphur, giving, in very minute quantities, a fine amethystine tint to the liquid.

Iodide of mercury has been proposed for a pigment. Orfila swallowed 6 grains of iodine; and was immediately affected with heat, constriction of the throat, nausea, eructation, salivation, and cardialgia. In ten minutes he had copious bilious vomitings, and slight colic pains. His pulse rose from 70 to about 90 beats in the minute. By swallowing large quantities of mucilage, and emollient clysters, he recovered, and felt nothing next day but slight fatigue. About 70 or 80 grains proved a fatal dose to dogs. They usually died on the fourth or fifth day.

Dr. Coindet of Geneva has recommended the use of iodine in the form of tincture, and also hydriodate of potassa or soda, as an efficacious remedy for the cure of glandular swellings, of the goitrous and scrophulous kind. I have found an ointment composed of 1 oz. hog's lard, and 1 drachm of iodide of zinc, a powerful external application in such cases. About a drachm of this ointment should be used in friction on the swelling once or twice a day."—*Ure's Chem. Dict.*

IODO-SULPHURIC ACID. "When sulphuric acid is poured, drop by drop, into a concentrated and hot aqueous solution of iodic acid, there immediately results a precipitate of iodo-sulphuric acid, possessed of peculiar properties. Exposed gradually to the action of a gentle heat, the iodo-sulphuric acid melts, and crystallises on cooling into rhomboids of a pale yellow colour. When strongly heated, it sublimes, and is partially decomposed; the latter portion being converted into oxygen, iodine, and sulphuric acid.

Phosphoric and nitric acids exhibit similar phenomena. These compound acids act with great energy on the metals. They dissolve gold and platinum."

IOLITE. Dichroite. Prismato-rhomboidal quartz of Mohs. This is of a colour intermediate between black, blue, and violet blue. When viewed in the direction of the axis of the crystals, the colour is dark indigo blue; but perpendicular to the axis of the crystals, pale brownish yellow. It comes from Finland.

I'ONIS. (From ιον, a violet.) A carbuncle of a violet colour.

IO'NTHUS. (From ιον, a violet, and ανθος, a flower.) A pimple in the face, of a violet colour.

IOTACI'SMUS. (From ιωτα, the Greek letter ι.) A defect in the tongue, or organs of speech, which renders a person incapable of pronouncing his letters.

IPECACUA'NHA. (An Indian word.) See *Callicocca ipecacuanha.*

IPOMŒA. (So called by Linnæus from ιψ, which he unaccountably mistakes for the convolvulus plant, whereas it means a creeping sort of worm that infests and corrodes vines, and ομοιὸς, like. By this appellation he evidently intended to express the close resemblance of *Ipomœa* to the genus *Convolvulus*, with which it agrees in habit altogether.) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia.*

IPOMŒA QUAMOCLIT. *Batata peregrina.* The cathartic potatoe. If about two ounces are eaten at bed time, they gently open the bowels by morning.

IQUETAIA. The inhabitants of the Brazils give this name to the *Scrophularia aquatica*, which is there celebrated as a corrector of the ill flavour of senna.

IRACU'NDUS. (From *ira*, anger: so called because it forms the angry look.) A muscle of the eye.

IRIDIUM. A metal found with another called osmium, in the black powder left after dissolving platinum. See *Platinum.*

I'RIS. (A rainbow: so called because of the variety of its colours.) 1. The anterior portion of the continuation of the choroid membrane of the eye, which is perforated in the middle by the pupil. It is of various colours. The posterior surface of the iris is termed the *uvea.* See *Choroid membrane.*

2. The *flower-de-luce*, from the resemblance of its flowers to the rainbow.

3. The name of a genus of plants in the Linnæan system. Class, *Triandria;* Order, *Monogynia.*

IRIS FLORENTINA. Florentine orris, or iris. The root of this plant, *Iris—corollis barbatis, caule foliis altiore subbifloro, floribus sessilibus*, of Linnæus, which is indigenous to Italy, in its recent state is extremely acrid, and, when chewed, excites a pungent heat in the mouth, that continues several hours: on being dried, this acrimony is almost wholly dissipated; the taste is slighly bitter, and the smell agreeable, and approaching to that of violets. The fresh root is cathartic, and for this purpose has been employed in dropsies. It is now chiefly used in its dried state, and ranked as a pectoral and expectorant, and hence has a place in the *trochisci amyli* of the pharmacopœias.

Iris, florentine. See *Iris florentina.*

IRIS GERMANICA. The systematic name of the common iris, or orris, or flower-de-luce. *Iris nostra.* The fresh roots of this plant, *Iris—corollis barbatis, caule foliis altiori multifloro, floribus inferioribus pedunculatis*, of Linnæus, have a strong disagreeable smell, and an acrid nauseous taste. They are powerfully cathartic, and are given in dropsical diseases, where such remedies are indicated.

IRIS NOSTRAS. See *Iris germanica.*

IRIS PALUSTRIS. See *Iris pseudacorus.*

IRIS PSEUDACORUS. The systematic name of the yellow water-flag. *Iris palustris; Gladiolus luteus; Acorus vulgaris.* This indigenous plant, *Iris—imberbis, foliis ensiformibus, petalis alternis, stigmatibus minoribus*, is common in marshes, and on the banks of rivers. It formerly had a place in the London Pharmacopœia, under the name of *Gladiolus luteus.* The root is without smell, but has an acrid styptic taste, and its juice, on being snuffed up the nostrils, produces a burning heat in the nose and mouth, accompanied by a copious discharge from these organs: hence it is recommended both as an errhine and sialagogue. Given internally, when perfectly dry, its adstringent qualities are such as to cure diarrhœas. The expressed juice is likewise said to be an useful application to serpiginous eruptions and scrophulous tumours.

Irish slate. See *Lapis Hybernicus.*

IRI'TIS. (*Iritis, idis.* f.; from *iris*, the name of the membrane.) Inflammation of the iris: it produces the symptoms of deep-seated or internal inflammation of the eye. See *Ophthalmia.*

IRON. *Ferrum.* Of all the metals, there is none which is so copiously and so variously dispersed through nature as iron. In animals, in vegetables, and in all parts of the mineral kingdom, we detect its presence. Mineralogists are not agreed with respect to the existence of native iron, though immense masses of it have been discovered, which could not have been the products of art; but there is much in favour of the notion that these specimens have been extracted by subterraneous fire. A mass of native iron, of 1600 pounds weight, was found by Pallas, on the river Denisei, in Siberia; and another mass of 300 pounds was found in Paraguay, of which specimens have been distributed every where. A piece of native iron, of two pounds weight, has been also met with at Kamsdorf, in the territories of Neustadt, which is still preserved there. These masses evidently did not originate in the places where they were found.

There are a vast variety of iron ores: they may, however, be all arranged under the following genera; namely, sulphurets, carburets, oxides, and salts of iron. The sulphurets of iron form the ores called *Pyrites*, of which there are many varieties. Their colour is, in general, a straw-yellow, with a metallic lustre; sometimes brownish, which sort is attracted by the magnet. They are often amorphous, and often also crystallised. Iron, in the state of a carburet, forms the *graphite* of Werner (*plumbago.*) This mineral occurs in kidney-form lumps of various sizes. Its colour is a dark iron-grey, or brownish black; when cut, bluish-grey. It has a metallic lustre. Its texture is fine-grained. It is very brittle. The combination of iron with oxygen is very abundant. The common *magnetic iron-stone*, or *load-stone*, belongs to this class: as does *specular iron ore*, and all the different ores called *hæmatites*, or *blood-stone*. Iron united to carbonic acid, exists in the *sparry iron ore*. Joined to arsenic acid, it exists in the ores called *arseniate of iron*, and *arseniate of iron and copper*.

Properties of iron.—Iron is distinguished from every other metal by its magnetical properties. It is attracted by the magnet, and acquires, under various conditions, the property of attracting other iron. Pure iron is of a whitish grey, or rather bluish colour, very slightly livid; but when polished, it has a great deal of brilliancy. Its texture is either fibrous, fine-grained, or in dense plates. Its specific gravity varies from 7.6 to 7.8. It is the hardest and most elastic of all the metals. It is extremely ductile, and may therefore be drawn into wire as fine as a human hair; it is also more tenacious than any other metal, and yields with facility to pressure. It is extremely infusible, and when not in contact with the fuel, it cannot be melted by the heat which any furnace can excite; it is, however, softened by heat, still preserving its ductility; and when thus softened, different pieces may be united; this constitutes the valuable property of *welding*. It is very dilatable by heat. It is the only metal which takes fire by the collision of flint. Heated in contact with air it becomes oxidised. If intensely and briskly heated, it takes fire with scintillation, and becomes a black oxide. It combines with carbon, and forms what is called steel. It combines with phosphorus in a direct and an indirect manner, and unites with sulphur readily by fusion. It decomposes water in the cold slowly, but rapidly when ignited. It decomposes most of the metallic oxides. All acids act upon iron. Very concentrated sulphuric acid has little or no effect upon it, but when diluted it oxidises it rapidly. The nitric acid oxidises it with great vehemence. Muriate of ammonia is decomposed by it. Nitrate of potassa detonates very vigorously with it. Iron is likewise dissolved by alkaline sulphurets. It is capable of combining with a number of metals. It does not unite with lead or bismuth, and very feebly with mercury. It detonates by percussion with the oxygenated muriates.

Method of obtaining iron.—The general process by which iron is extracted from its ores, is first to roast them by a strong heat, to expel the sulphur, carbonic acid, and other mineralizers which can be separated by heat. The remaining ore, being reduced to small pieces, is mixed with charcoal, or coke; and is then exposed to an intense heat, in a close furnace, excited by bellows; the oxygen then combines with the carbon, forming carbonic acid gas during the process, and the oxide is reduced to its metallic state. There are likewise some fluxes necessary in order to facilitate the separation of the melted metal. The matrix of the iron ore is generally either argillaceous or calcareous, or sometimes a portion of silicious earth; but whichever of these earths is present, the addition of one or both of the others makes a proper flux. These are therefore added in due proportion, according to the nature of the ores; and this mixture, *in contact with the fuel*, is exposed to a heat sufficient to reduce the oxide to its metallic state.

The metal thus obtained, and called smelted, pig, or cast iron, is far from being pure, always retaining a considerable quantity of carbon and oxygen, as well as several heterogeneous ingredients. According as one or other of these predominates, the property of the metal differs. Where the oxygen is present in a large proportion, the colour of the iron is whitish grey; it is extremely brittle, and its fracture exhibits an appearance of crystallisation: where the carbon exceeds, it is of a dark grey, inclining to blue or black, and is less brittle. The former is the *white*, the latter the *black crude iron of commerce*. The *grey* is intermediate to both. In many of these states, the iron is much more fusible than when pure: hence it can be fused and cast into any form; and when suffered to cool slowly, it crystallizes in octahedra: it is also much more brittle, and cannot therefore be either flattened under the hammer, or by the laminating rollers.

To obtain the iron more pure, or to free it from the carbon with which it is combined in this state, it must be refined by subjecting it to the operations of melting and forging. By the former, in which the metal is kept in fusion for some time, and constantly kneaded and stirred, the carbon and oxygen it contains are partly combined, and the produced carbonic acid gas is expelled: the metal at length becomes viscid and stiff; it is then subjected to the action of a very large hammer, or to the more equal, but less forcible pressure of large rollers, by which the remaining oxide of iron, and other impurities, not consumed by the fusion, are pressed out. The iron is now no longer granular nor crystallised in its texture; it is fibrous, soft, ductile, malleable, and totally infusible. It is termed forged, wrought, or bar iron, and is the metal in a purer state, though far from being absolutely pure.

The compounds of iron are the following:

1. *Oxides;* of which there are two, or perhaps, three.

1*st*, The oxide, obtained either by digesting an excess of iron filings in water, by the combustion of iron wire in oxygen, or by adding pure ammonia to solution of green copperas, and drying the precipitate out of contact of air, is of a black colour, becoming white by its union with water, in the hydrate, attractible by the magnet, but more feebly than iron. By a mean of the experiments of several chemists, its composition seems to be,

Iron,	100	77.82	3.5
Oxygen,	28.5	22.18	1.0

2*d*., Deutoxide of Gay Lussac. He forms it by exposing a coil of fine iron wire, placed in an ignited porcelain tube, to a current of steam, as long as any hydrogen comes over. There is no danger, he says, of generating peroxide in this experiment, because iron once in the state of deutoxide, has no such affinity for oxygen as to enable it to decompose water. It may also, he states, be procured by calcining strongly a mixture of 1 part of iron and 3 parts of the red oxyde in a stone ware crucible, to the neck of which a tube is adapted to cut off the contact of air. But this process is less certain than the first, because a portion of peroxide may escape the reaction of the iron. But we may dispense with the trouble of making it, adds Thenard, because it is found abundantly in nature. He refers to this oxide, the crystallised specular iron ore of Elba, Corsica, Dalecarlia, and Sweden. He also classes under this oxide all the magnetic iron ores; and says, that the above described protoxide does not exist in nature. From the synthesis of this oxide by steam, Gay Lussac has determined its composition to be,

Iron,	100	72.72
Oxygen,	37.5	27.28

3*d*, The red oxide. It may be obtained by igniting the nitrate, or carbonate; by calcining iron in open vessels; or simply by treating the metal with strong nitric acid, then washing and drying the residuum. Colcothar of vitriol, or thorough calcined copperas, may be considered as peroxide of iron. It exists abundantly native in the red iron ores. It seems to be a compound of,

Iron,	100	70=4 primes,
Oxygen,	43	30=3 primes.

2. *Chlorides* of iron; of which there are two, first examined in detail by Dr. John Davy.

The protochloride may be procured by heating to redness, in a glass tube with a very small orifice, the residue which is obtained by evaporating to dryness the green muriate of iron. It is a fixed substance, requiring a red heat for its fusion. It has a greyish variegated colour, a metallic splendour, and a lamellar texture.

The deutochloride may be formed by the combustion of iron wire in chlorine gas, or by gently heating the green muriate in a glass tube. It is the volatile compound described by Sir H. Davy in his celebrated Bakerian lecture on oxymuriatic acid. It condenses after sublimation, in the form of small brilliant iridescent plates.

3. For the *iodide* of iron, see *Iodine.*

4. *Sulphurets* of iron; of which, according to Porrett, there are four, though only two are usually described, his protosulphuret and persulphuret.

5. *Carburets* of iron. These compounds form steel, and probably cast-iron; though the latter contains also some other ingredients. The latest practical researches on the constitution of these carburets, are those of Daniel.

6. *Salts of iron.*

1. *Protacetate of iron* forms small prismatic crystals, of a green colour, a sweetish styptic taste.

2. *Peracetate of iron* forms a reddish-brown uncrystallisable solution, much used by the calico-printers, and prepared by keeping iron turnings, or pieces of old iron, for six months immersed in redistilled pyrolignous acid.

3. *Protarseniate of iron* exists native in crystals, and may be formed in a pulverulent state, by pouring arseniate of ammonia into sulphate of iron.

4. *Perarseniate of iron* may be formed by pouring arseniate of ammonia into peracetate of iron; or by boiling nitric acid on the protarseniate. It is insoluble.

5. *Antimoniate of iron* is white, becoming yellow, insoluble.

6. *Borate*, pale yellow, insoluble.
7. *Benzoate*, yellow, insoluble.
8. *Protocarbonate*, greenish, soluble.
9. *Percarbonate*, brown, insoluble.
10. *Chromate*, blackish, do.
11. *Protocitrate*, brown-crystals, soluble.
12. *Protoferroprussiate*, white, insoluble.
13. *Perferroprussiate*, white, do.

This constitutes the beautiful pigment called prussian blue.

14. *Protogallate*, colourless, soluble.
15. *Pergallate*, purple, insoluble.
16. *Protomuriate*, green crystals, very soluble.
17. *Permuriate*, brown, uncrystallizable, very soluble.
18. *Protonitrate*, pale green, soluble.
19. *Pernitrate*, brown, do.
20. *Protoxalate*, green prisms, do.
21. *Peroxalate*, yellow, scarcely soluble.
22. *Protophosphate*, blue, insoluble.
23. *Perphosphate*, white, do.
24. *Protosuccinate*, brown crystals, soluble.
25. *Persuccinate*, brownish-red, insoluble.
26. *Protosulphate*, green vitriol, or copperas. It is generally formed by exposing native pyrites to air and moisture, when the sulphur and iron both absorb oxygen, and form the salt.
27. *Persulphate.* Of this salt there seems to be four or more varieties, having a ferreous base, which consists by Porrett, of 4 primes iron + 3 oxygen = 10 in weight, from which their constitution may be learned.

The tartrate and pertartrate of iron may also be formed; or by digesting cream of tartar with water or iron filings, a triple salt may be obtained, formerly called tartarized tincture of Mars.

These salts have the following general characters:—

1. Most of them are soluble in water; those with the protoxide for a base, are generally crystallisable; those with the peroxide, are generally not; the former are insoluble, the latter soluble in alkohol.

2. Ferroprussiate of potassa throws down a blue precipitate, or one becoming blue in the air.

3. Infusion of galls gives a dark purple precipitate, or one becoming so in the air.

4. Hydrosulphuret of potassæ or ammonia gives a black precipitate; but sulphuretted hydrogen merely deprives the solutions of iron of their yellow-brown colour.

5. Phosphate of soda gives a whitish precipitate.

6. Benzoate of ammonia, yellow.

7. Succinate of ammonia, flesh-coloured with the peroxide.

The general medicinal virtues of iron, and the several preparations of it, are to constringe the fibres, to quicken the circulation, to promote the different secretions in the remoter parts, and at the same time to repress inordinate discharges into the intestinal tube. By the use of chalybeates, the pulse is very sensibly raised, the colour of the face, though before pale, changes to a florid red; the alvine, urinary, and cuticular excretions, are increased.

When given improperly, or to excess, iron produces headache, anxiety, heats the body, and often causes hæmorrhages, or even vomiting, pains in the stomach, spasms, and pains of the bowels.

Iron is given in most cases of debility and relaxation; in passive hæmorrhages; in dyspepsia, hysteria, and chlorosis; in most of the cachexiæ; and it has lately been recommended as a specific in cancer. Where either a preternatural discharge, or suppression of natural secretions, proceeds from a languor, or sluggishness of the fluids, and weakness of the solids, this metal, by increasing the motion of the former and the strength of the latter, will suppress the flux, or remove the suppression; but where the circulation is already too quick, the solids too tense and rigid, where there is any stricture, or spasmodic contraction of the vessels, iron, and all the preparations of it, will aggravate both diseases. Iron probably has no action on the body when taken into the stomach, unless it be oxidised. But during its oxidisement, hydrogen gas is evolved, and accordingly we find that fœtid eructations and black fæces are considered as proofs of the medicine having taken effect. It can only be exhibited internally in the state of filings, which may be given in doses from five to twenty grains. Iron wire is to be preferred for pharmaceutical preparations, both because it is the most convenient form, and because it is the purest iron.

The medicinal preparations of iron now in use are:—

1. Subcarbonas ferri. See *Ferri subcarbonas.*
2. Sulphas ferri. See *Ferri sulphas.*
3. Ferrum tartarizatum. See *Ferrum tartarizatum.*
4. Liquor ferri alkalini. See *Ferri alkalini liquor.*
5. Tinctura acetatis ferri. See *Tinctura ferri acetatis.*
6. Tinctura muriatis ferri. See *Tinctura ferri muriatis.*
7. Tinctura ferri ammoniati. See *Tinctura ferri ammoniati.*
8. Vinum ferri. See *Vinum ferri.*
9. Ferrum ammoniatum. See *Ferrum ammoniatum.*
10. Oxydum ferri rubrum. See *Oxydum ferri rubrum.*
11. Oxydum ferri nigrum. See *Oxydum ferri nigrum.*

IRON-FLINT. This occurs in veins of ironstone, and in trap-rocks, near Bristol, and in many parts of Germany.

IRRITABILITY. (*Irritabilitas;* from *irrito,* to provoke.) *Vis insita* of Haller. *Vis vitalis* of Goerter. Oscillation of Boerhaave. Tonic power of Stahl. Muscular power of Bell. Inherent power of Cullen. The contractility of muscular fibres, or a property *peculiar* to muscles, by which they contract upon the application of certain stimuli, without a consciousness of action. This power may be seen in the tremulous contraction of muscles when lacerated, or when entirely separated from the body in operations. Even when the body is dead to all appearance, and the nervous power is gone, this contractile power remains till the organisation yields, and begins to be dissolved. It is by this inherent power that a cut muscle contracts, and leaves a gap, that a cut artery shrinks and grows stiff after death This irritability of muscles is so far independent of nerves, and so little connected with feeling, which is the province of the nerves, that, upon stimulating any muscle by touching it with caustic, or irritating it with a sharp point, or driving the electric spark through it, or exciting with the metallic conductors, as those of silver, or zinc, the muscle instantly contracts, although the nerve of that muscle be tied; although the nerve be cut so as to separate the muscle entirely from all connection with the system; although the muscle be separated from the body; although the creature upon which the experiment is performed may have lost all sense of feeling, and have been long apparently dead. Thus a muscle, cut from the limb, trembles and palpitates a long time after; the heart, separated from the body, contracts when irritated; the bowels, when torn from the body, continue their peristaltic motion, so as to roll upon the table, ceasing to answer to stimuli only when they become stiff and cold; and too often, in the human body, the vis insita loses the exciting power of the nerves, and then palsy ensues; or, losing all governance of the nerves, the vis insita, acting without the regulating power, falls into partial or general convulsions. Even in vegetables, as in the sensitive plant, this contractile power lives. Thence comes the distinction between the irritability of muscles and the sensibility of nerves: for the *irritability* of muscles survives the animals, as when it is active after death: survives the life of the part, or the feelings of the whole system, as in universal palsy, where the vital motions continue entire and perfect, and where the muscles, though not obedient to the will, are subject to irregular and violent actions; and it survives the connection with the rest of the system, as when animals very tenacious of life, are cut into parts; but *sensibility*, the property of the nerves, gives the various modifications of sense, as vision, hearing, and the rest; gives also the general sense of pleasure or pain, and makes the system, according to its various conditions, feel vigorous and healthy, or weary and low. And thus the eye feels and the skin feels: but their appointed stimuli produce no emotions in these parts; they are sensible, but not irritable. The heart, the intestines, the urinary bladder, and all the muscles of voluntary motion, answer to stimuli with a quick and forcible contraction; and yet they hardly feel the stimuli by which these contractions are produced, or at least, they do not convey that feeling to the brain. There is no consciousness of present stimulus in those parts which are called into action by the impulse of the nerves, and at the command of the will; so that muscular parts have all the irritability of the system, with but little feeling, and that little owing to the nerves which enter into their substance; while nerves have all the sensibility of the system, but no motion.

The discovery of this singular property belongs to our countryman Glisson; but Baron Haller must be considered as the first who clearly pointed out its existence, and proved it to be the cause of muscular motion.

The laws of irritability, according to Dr. Crichton, are, 1. After every action in an irritable part, a state of rest, or cessation from motion, must take place before the irritable part can be again incited to action. If, by an act of volition, we throw any of our muscles into action, that action can only be continued for a certain space of time; the muscle becomes relaxed, notwithstanding all our endeavours to the contrary, and remains a certain time in that relaxed state, before it can be again thrown into action. 2. Each irritable part has a certain portion or quantity of the principle of irritability which is natural to it, part of which it loses during action, or from the application of stimuli. 3. By a process wholly unknown to us, it regains this lost quantity during its repose or state of rest. In order to express the different quantities of irritability in any part, we say that it is either more or less redundant, or more or less defective. It becomes redundant in a part when the stimuli which are calculated to act on that part are withdrawn, or withheld for a certain length of time, because then no action can take place; while, on the other hand, the application of stimuli causes it to be exhausted, or to be deficient, not only by exciting action, but by some secret influence, the nature of which has not yet been detected; for it is a circumstance extremely deserving of attention, that an irritable part, or body, may be suddenly deprived of its irritability by powerful stimuli, and yet no apparent muscular or vascular action takes place at the time. A certain quantity of spirits, taken at once into the stomach, kills almost as instantaneously as lightning does: the same thing may be observed of some poisons, as opium, distilled laurel-water, the juice of the cerbera ahovai, &c. 4. Each irritable part has stimuli which are peculiar to it, and which are intended to support its natural action: thus, blood, which is the stimulus proper to the heart and arteries, if, by any accident it gets into the stomach, produces sickness, or vomiting. If the gall, which is the natural stimulus to the ducts of the liver, the gall-bladder, and the intestines, is by any accident effused into the cavity of the peritonæum, it excites too great action of the vessels of that part, and induces inflammation. The urine does not irritate the tender fabric of the kidneys, ureters, or bladder, except in such a degree as to preserve their healthy action; but if it be effused into the cellular membrane, it brings on such a violent action of the vessels of these parts, as to produce gangrene. Such stimuli are called *habitual* stimuli of parts. 5. Each irritable part differs from the rest in regard to the quantity of irritability which it possesses. This law explains to us the reason of the great diversity which we observe in the action of various irritable parts: thus the muscles of voluntary motion can remain a long time in a state of action, and if it be continued as long as possible, another considerable portion of time is required before they regain the irritability they lost; but the heart and arteries have a more short and sudden action, and their state of rest is equally so. The circular muscles of the intestines have also a quick action and short rest. The urinary bladder does not fully regain the irritability it loses during its contraction for a considerable space of time; the vessels which separate and throw out the menstrual discharge, act, in general, for three or four days, and do not regain the irritability they lose for a lunar month. 6. All stimuli produce action in proportion to their irritating powers. As a person approaches his hand to the fire, the action of all the vessels in the skin is increased, and it glows with heat; if the hand be approached still nearer, the action is increased to such an unusual degree as to occasion redness and pain; and if it be continued too long, real inflammation takes place; but if this heat be continued, the part at last loses its irritability, and a sphacelus or gangrene ensues.

7. The action of every stimulus is in an inverse ratio to the frequency of its application. A small quantity of spirits taken into the stomach, increases the action of its muscular coat, and also of its various vessels, so that digestion is thereby facilitated. If the same quantity, however, be taken frequently, it loses its effect. In order to produce the same effect as at first, a larger quantity is necessary; and hence the origin of dram-drinking. 8. The more the irritability of a part is accumulated, the more that part is disposed to be acted upon. It is on this account that the activity of all animals, while in perfect health, is much livelier in the morning than at any other part of the day; for, during the night, the irritability of the whole frame, and especially that of the muscles destined for labour, viz the muscles for voluntary action, is re-accumulated. The same law explains why digestion goes on more rapidly the first hour after food is swallowed than at any other time; and it also accounts for the great danger that accrues to a famished person upon first taking in food. 9. If the stimuli which keep up the action of any irritable body be withdrawn for too great a length of time, that process on which the formation of the principle depends is gradually diminished, and at last entirely destroyed. When the irritability of the system is too quickly exhausted by heat, as is the case in certain warm climates, the application of cold invigorates the frame, because cold is a mere diminution of the overplus of that stimulus which was causing the rapid consumption of the principle. Under such or similar circumstances, therefore, cold is a tonic remedy; but if, in a climate naturally cold, a person were to go into a cold bath, and not soon return into a warmer atmosphere, it would destroy life just in the same manner as many poor people who have no comfortable dwellings are often destroyed from being too long exposed to the cold in winter. Upon the first application of cold the irritability is accumulated, and the vascular system therefore is exposed to great action; but, after a certain time, all action is so much diminished, that the process, whatever it be, on which the formation of the irritable principle depends, is entirely lost. For further information on this interesting subject, see Dr. Crichton on Mental Derangement.

IRRITATION. *Irritatio.* The action produced by any stimulus.

ISATIS. (Ιϛατις of Dioscorides, and *Isatis* of Pliny, the derivation of which is unknown.) The name of a genus of plants in the Linnæan system. Class, *Tetradynamia*; Order, *Siliquosa.*

ISATIS TINCTORIA. *Glastum.* The systematic name of the plant used for dyeing, called woad. It is said to be adstringent.

I'SCA. A sort of fungous excrescence of the oak, or of the hazel, &c. The ancients used it as the moderns used moxa.

ISCHÆ'MON. (From *ισχω*, to restrain, and *αιμα*, blood.) A name for any medicine which restrains or stops bleeding.

ISCHÆ'MUM. A species of *Andropogon.*

I'SCHIAS. (Ισχιας; from *ισχιον*, the hip.) A rheumatic affection of the hip-joint. See *Rheumatismus.*

ISCHIATOCE'LE. (From *ισχιον*, the hip, and *κηλη*, a rupture.) *Ischiocele.* An intestinal rupture, through the sciatic ligaments.

ISCHIO-CAVERNOSUS. See *Erector penis.*

ISCHIOCE'LE. See *Ischiatocele.*

I'SCHIUM. (From *ισχις*, the loin: so named because it is near the loin.) A bone of the pelvis of the fœtus, and a part of the os innominatum of the adult. See *Innominatum os.*

ISCHNOPHO'NIA. (From *ισχνος*, slender, and *φωνη*, the voice.) 1. A shrillness of the voice.

2. A hesitation of speech, or a stammering.

ISCHURE'TICA. (From *ισχουρια*, a suppression of the urine.) Medicines which relieve a suppression of the urine.

ISCHU'RIA. (From *ισχω*, to restrain, and ουρον, the urine.) A suppression of urine. A genus of disease in the class *Locales*, and order *Epischeses*, of Cullen. There are four species of ischuria:

1. *Ischuria renalis*, coming after a disease of the kidneys, with a troublesome sense of weight or pain in that part.

2. *Ischuria ureterica*, after a disease of the kidneys, with a sense of pain or uneasiness in the course of the ureters.

3. *Ischuria vesicalis*, marked by a frequent desire to make water, with a swelling of the hypogastrium, and pain at the neck of the bladder.

4. *Ischuria urethralis*, marked by a frequent desire to make water, with a swelling of the hypogastrium, and pain of some part of the urethra.

When there is a frequent desire of making water, attended with much difficulty in voiding it, the complaint is called a dysury, or strangury; and when there is a total suppression of urine, it is known by the name of an ischury. Both ischuria and dysuria are distinguished into acute, when arising in consequence of inflammation: and chronic, when proceeding from any other cause, such as calculus, &c.

The causes which give rise to these diseases are an inflammation of the urethra, occasioned either by venereal sores or by a use of acrid injections, tumour or ulcer of the prostate gland, inflammation of the bladder or kidneys, considerable enlargements of the hæmorrhoidal veins, a lodgement of indurated fæces in the rectum, spasm at the neck of the bladder, the absorption of cantharides applied externally, or taken internally, and excess in drinking either spirituous or vinous liquors; but particles of gravel sticking at the neck of the bladder, or lodging in the urethra, and thereby producing irritation, prove the most frequent cause. Gouty matter falling on the neck of the bladder, will sometimes occasion these complaints.

In dysury there is a frequent inclination to make water, attended with a smarting pain, heat, and difficulty in voiding it, together with a sense of fulness in the region of the bladder. The symptoms often vary, however, according to the cause which has given rise to it. If it proceeds from a calculus in the kidney, or ureter, besides the affections mentioned, it will be accompanied with nausea, vomiting, and acute pains in the loins and regions of the ureter and kidney of the side affected. When a stone in the bladder, or gravel in the urethra, is the cause, an acute pain will be felt at the end of the penis, particularly on voiding the last drops of urine, and the stream of water will either be divided into two, or be discharged in a twisted manner, not unlike a corkscrew. If a scirrhus of the prostate gland has occasioned the suppression or difficulty of urine, a hard indolent tumour, unattended with any acute pain, may readily be felt in the perinæum, or by introducing the finger in ano.

Dysury is seldom attended with much danger, unless, by neglect, it should terminate in a total obstruction. Ischury may always be regarded as a dangerous complaint, when it continues for any length of time, from the great distention and often consequent inflammation which ensue. In those cases where neither a bougie nor a catheter can be introduced, the event, in all probability, will be fatal, as few patients will submit to the only other means of drawing off the urine before a considerable degree of inflammation and tendency to gangrene have taken place.

ISERINE. (So called from the river Iser, near the origin of which it is found.) An iron black-coloured ore.

ISINGLASS. See *Ichthyocolla.*

ISO′CHRONOS. (From ισος, equal, and χρονος, time.) Preserving an equal distance of time between the beats; applied to the pulse.

ISO′CRATES. (From ισος, equal, and κεραννυμι, to mix.) Wine mixed with an equal quantity of water.

ISO′DROMUS. (From ισος, equal, and δρόμος, a course.) The same as *Isochronos.*

ISOPY′RUM. (From ισος, equal, and πυρ, fire: so named from its flame-coloured flower.) The *Aquilegia vulgaris.*

ISO′TONUS. (From ισος, equal, and τόνος, extension.) Applied to fevers which are of equal strength during the whole of the paroxysm.

I′SSUE. *Fonticulus.* An artificial ulcer made by cutting a portion of the skin, and burying a pea or some other substance in it, so as to produce a discharge of purulent matter.

I′STHMION. (From ισθμος, a narrow piece of land between two seas.) The fauces narrow passage between the mouth and gullet.

ISTHMUS VIEUSSENII. The ridge surrounding the remains of the foramen ovale, in the right auricle of the human heart.

ITHMOI′DES. See *Ethmoïdes.*

ITINERA′RIUM. (From *iter*, a way.) The catheter; also a staff used in cutting for the stone.

ITIS. From the time of Boerhaave, visceral inflammations have been generally distinguished by anatomical terms derived from the organ affected, with the Greek term *itis*, added as a suffix; as *cephalitis*, &c. *Itis* is sufficiently significant of its purpose; it is immediately derived from ιεμαι, which is itself a ramification from εω, and imports, not merely action, "putting or going forth," which is the strict and simple meaning of εω, but action in its fullest urgency, "violent or impetuous action." When this term then is added to the genitive case of the Greek name of an organ, it means inflammation of that viscus: hence *hepatitis*, *nephritis*, *gastritis*, *carditis*, mean inflammation of the liver, kidney, stomach, heart.—*Good.*

I′VA PECANGA. See *Smilax sarsaparilla.*

IVORY. The tusk, or tooth of defence of the male elephant. It is an intermediate substance between bone and horn. The dust is occasionally boiled to form jelly, instead of isinglass, for which it is a bad substitute. In 100 parts there are 24 gelatin, 64 phosphate of lime, and 0.1 carbonate of lime.

IVY. See *Hedera helix.*

Ivy, ground. See *Glecoma hederacea.*

Ivy-gum. See *Hedera helix.*

I′XIA. (From ιξος, glue.) 1. A name of the *Carlina gummifera*, from its viscous juice.

2. (From ιξομαι, to proceed from.) A preternatural distention of the veins.

IXINE. See *Carlina gummifera.*

J.

JA'CEA. (*Quia prodest hominibus tristitia jacentibus*; because it resists sorrow; or from ιαομαι, to heal.) The herb pansey, or heart's-ease. See *Viola tricolor.*

JACERANTA TINGA. See *Acorus calamus.*

JACI'NTHUS. See *Hyacinthus.*

Jack-by-the-hedge. See *Erysimum alliaria.*

JACOBÆ'A. (Named because it was dedicated to St. James, or because it was directed to be gathered about the feast of that saint.) See *Senecio Jacobæa.*

JADE. See *Nephrite.*

Jagged leaf. See *Erosus.*

JALAP. See *Convolvulus jalapa.*

JALA'PA. See *Convolvulus jalapa.*

JALA'PIUM. (From *Chalapa*, or *Xalapa*, in New Spain, whence it is brought.) See *Convolvulus jalapa.*

JALAPPA ALBA. White jalap. See *Convolvulus mecoacan.*

JAMAICA BARK. See *Cinchona caribæa.*

JAMAICA PEPPER. See *Myrtus pimenta.*

JA'MBLICHI SALES. A preparation with sal-ammoniac, some aromatic ingredients, &c. so called from Jamblichus, the inventor.

JA'NITOR. (From *janua*, a gate.) The pylorus, so called from its being, as it were, the door or entrance of the intestines.

Japan earth. See *Acacia catechu.*

JAPO'NICA TERRA. (So called from the place it came from.) See *Acacia catechu.*

JARGON. See *Zircon.*

JA'SMINUM. (*Jasminum*; from *jasmen*, Arab.; or from ιον, a violet, and οσμη, odour, on account of the fine odour of the flowers.) 1. The name of a genus of plants in the Linnæan system. Class, *Diandria*; Order, *Monogynia.*

2. The pharmacopœial name of the jessamine. See *Jasminum officinale.*

JASMINUM OFFICINALE. The systematic name of the jessamine-tree. The flowers of this beautiful plant have a very fragrant smell, and a bitter taste. They afford, by distillation, an essential oil, which is much esteemed in Italy to rub paralytic limbs, and in the cure of rheumatic pains.

JASPER. A subspecies of rhomboidal quartz, according to Jameson, who enumerates five kinds: Egyptian, striped, porcelain, common, agate jasper.

JA'TROPHA. (Most probably from ιατρος, a physician.) The name of a genus of plants in the Linnæan system. Class, *Monœcia*; Order, *Monadelphia.*

JATROPHA CURCAS. The systematic name of a plant the seeds of which resemble the castor-oil seeds. *Ricinus major; Ricinoides; Pineus purgans; Pinhones indici; Faba cathartica; Nux cathartica; Americana; Nux barbadensis.* The seed or nut so called in the pharmacopœias is oblong and black, the produce of the *Jatropha—foliis cordatis angulatis* of Linnæus. It affords a quantity of oil, which is given, in many places, as the castor-oil is in this country, to which it is very nearly allied. The seeds of the *Jatropha multifida* are of an oval and triangular shape, of a pale brown colour, are called purging-nuts, and give out a similar oil.

JATROPHA ELASTICA. The juice of this plant affords an elastic gum. See *Caoutchouc.*

JATROPHA MANIHOT. This is the plant which affords the Cassada root. *Cassada; Cacavi; Cassave; Cassava; Pain de Madagascar; Ricinus minor; Maniot; Yucca; Manibar; Aipi; Aipima coxera; Aipipoca; Janipha.* The leaves are boiled, and eaten as we do spinach. The root abounds with a milky juice, and every part, when raw, is a fatal poison. It is remarkable that the poisonous quality is destroyed by heat: hence the juice is boiled with meat, pepper, &c. into a wholesome soup, and what remains after expressing the juice, is formed into cakes or meal, the principal food of the inhabitants. This plant, which is a native of three quarters of the world, is one of the most advantageous gifts of Providence, entering into the composition of innumerable preparations of an economical nature.

Cassada roots yield a great quantity of starch, called tapioca, exported in little lumps by the Brazilians, and now well known to us as a diet for sick and weakly persons.

JEBB, JOHN, was born at London in 1736. He was originally devoted to the church, and, after studying at Cambridge, entered into orders, and obtained a living in Norfolk in 1764. The year following, he published, in conjunction with two friends, a selection from Newton's Principia, with notes, which was highly esteemed. He soon after returned to Cambridge, and engaged warmly as an advocate for a reform in church and state, as well as in the discipline of that university. At length, in 1775, he resigned all his offices in the church, the established doctrines of which he did not approve; and determined upon entering into the medical profession. He soon qualified himself for this, obtained a diploma from St. Andrews, and was admitted a licentiate of the London College of Physicians; and in the same year, 1778, he was elected a fellow of the Royal Society. In 1782, he published "Select Cases of Paralysis of the Lower Extremities;" which tend to support the practice of Pott, of applying caustics near the spine. To this work is added, an interesting description of a very rare disease, catalepsy. The warmth of his political sentiments, however, obstructed his professional career; and the various fatigues, and anxieties, to which he exposed himself, in order to further his benevolent designs, exhausted his constitution so much, that he sunk a premature victim in 1786.

JECORA'RIA. (From *jecur*, the liver: so named from its supposed efficacy in diseases of the liver.) 1. The name of a plant. See *Marchantia polymorpha.*

2. A name given to a vein in the right hand because it was usually opened in diseases of the liver.

JE'CUR. (*Jecur, oris.* or *jecinoris*, neut.) The liver. See *Liver.*

JECUR UTERINUM. The placenta is, by some, thus called, from the supposed similitude of its office with that of the liver.

JEJU'NUM. (From *jejunus*, empty.) *Jejunum intestinum.* The second portion of the small intestines, so called because it is mostly found empty. See *Intestine.*

JELLY. See *Gelatin.*

JENITE. See *Lievrite.*

Jerusalem cowslips. See *Pulmonaria officinalis.*

Jerusalem oak. See *Chenopodium botrys.*

Jerusalem sage. See *Pulmonaria officinalis.*

JESSAMINE. See *Jasminum.*

Jesuita'nus cortex. (From *jesuita*, a jesuit.) A name of the Peruvian bark, because it was first introduced into Europe by Father de Lugo, a jesuit. See *Cinchona.*

Jesui'ticus cortex. See *Cinchona.*

Jesuit's bark. See *Cinchona.*

JET. (So called from the river *Gaza*, in Lesser Asia, from whence it came.) A black bituminous coal, hard and compact, found in great abundance in various parts of France, Sweden, Germany, and Ireland. It is brilliant and vitreous in its fracture, and capable of taking a good polish by friction; it attracts light substances, and appears to be electric, like amber; hence it has been called *black amber.* It has no smell, but when heated, it acquires one like bitumen judaicum.

Jew's pitch. See *Bitumen judaicum.*

JOHN'S WORT. See *Hypericum.*

Jointed leaf. See *Articulatus.*

JUDGMENT. The judgment is the most important of the intellectual faculties. We acquire all our knowledge by this faculty; without it our life would be merely vegetative; we would have no idea either of the existence of other bodies, or of our own: for these two sorts of notions, like our knowledge, are the consequence of our faculty of judging.

To judge is to establish a relation between two ideas, or between two groups of ideas. When I judge of the goodness of a work, I feel that the idea of goodness belongs to the book which I have read; I establish a relation, I form to myself an idea of a different kind from that which arises from sensibility and memory.

A continuation of judgments linked together form an inference, or process of reasoning.

We see how important it is to judge justly, that is, to establish only those relations which really exist. If I judge that a poisonous substance is salutary, I am in danger of losing my life; my false judgment is therefore hurtful. It is the same with all those of the same kind. Almost all the misfortunes which oppress man in a moral sense, arise from errors of judgment; crimes, vices, bad conduct, spring from false judgment.

The science of logic has for its end the teaching of just reasoning: but pure judgment, or good sense, and false judgment, or *wrong-headedness*, depend on organisation. We cannot change in this respect: we must remain as nature has made us. There are men endowed with the precious gift of finding relations of things which had never been perceived before. If these relations are very important, and beneficial to humanity, the authors are men of genius: if the relations are of less importance, they are considered men of wit, imagination. Men differ principally by their manner of feeling different relations, or of judging. The judgment seems to be injured by an extreme vivacity of sensations; hence we see that faculty become more perfect with age.—*Magendie's Physiology.*

Judicato'rius. (From *judico*, to discern.) An obsolete term applied to a synocha of four days, because its termination may certainly be foreseen.

JUGA'LE OS. (*Jugalis;* from *jugum*, a yoke: from its resemblance, or because it is articulated to the bone of the upper jaw, like a yoke.) *Os malæ; Os zygomaticum.* The ossa malarum are the prominent square bones which form the upper part of the cheeks. They are situated close under the eyes, and make part of the orbit. Each of these bones has three surfaces to be considered. One of these is exterior and somewhat convex. The second is superior and concave, serving to form the lower and lateral parts of the orbit. The third, which is posterior, is very unequal and concave, for the lodgement of the lower part of the temporal muscle. Each of these bones may be described as having four processes formed by their four angles. Two of these may be called *orbitar* processes. The superior one is connected with the orbitar process, of the os frontis; and the inferior one with the malar process of the maxillary bone. The third is connected with the temporal process of the sphenoid bone; and the fourth forms a bony arch, by its connection with the zygomatic process of the temporal bone. In infants, these bones are entire and completely ossified.

JU'GLANS. (*Quasi Jovis glans*, the royal fruit, from its magnitude.) 1. The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Polyandria.* The walnut tree.

2. The pharmacopœial name of the walnut. See *Juglans regia.*

Juglans regia. The systematic name of the walnut tree. The tree which bears the walnut is the *Juglans—foliolis ovalibus glabris subserratis subæqualibus* of Linnæus. It is a native of Persia, but cultivated in this country. The unripe fruit, which has an astringent bitterish taste, and has been long employed as a pickle, is the part which was directed for medicinal use by the London College, on account of its anthelmintic virtues. An extract of the green fruit is the most convenient preparation, as it may be kept for a sufficient length of time, and made agreeable to the stomach of the patient, by mixing it with cinnamon water.

The *putamen*, or green rind of the walnut, has been celebrated as a powerful anti-venereal remedy, for more than a century and a half; and Petrus Borellus has given directions for a decoction not unlike that which is commonly called the Lisbon diet-drink, in which the walnut, with its green bark, forms a principal ingredient. Ramazzini, whose works were published early in the present century, has likewise informed us, that in his time, the green rind of the walnut was esteemed a good anti-venereal remedy in England. This part of the walnut has been much used in decoctions, during the last fifty years, both in the green and dried state; it has been greatly recommended by writers on the continent, as well as by those of our own country; and is, without doubt, a very useful addition to the decoction of the woods. Pearson has employed it during many years, in those cases where pains in the limbs and indurations of the membranes have remained, after the venereal disease has been cured by mercury; and he informs us, that he has seldom directed it without manifest advantage.

Brambilla and Girtanner also contend for the anti-venereal virtues of the green bark of the walnut: but the result of Pearson's experience will not permit him to add his testimony to theirs. I have given it, says he, in as large doses as the stomach could retain, and for as long a time as the strength of the patients, and the nature of their complaints would permit; but I have uniformly observed, that if they who take it be not previously cured of *lues venerea*, the peculiar symptoms will appear, and proceed in their usual course, in defiance of the powers of this medicine. The *Decoctum Lusitanicum* may be given with great advantage in many of those cutaneous diseases, which are attended with aridity of the skin; and I have had some opportunities of observing, that when the putamen of the walnut has been omitted, either intentionally or by accident, the same good effects have not followed the taking of the decoction, as when it contained this ingredient. See *Juglans.*

JUGULAR. (*Jugularis; from jugulum,* the throat.) Belonging to the throat.

JUGULAR VEINS. The veins so called run from the head down the sides of the neck, and are divided, from their situation, into external and internal. The *external, or superficial jugular vein,* receives the blood from the frontal, angular, temporal, auricular, sublingual, or ranine, and occipital veins. The *internal,* or *deep-seated jugular vein,* receives the blood from the lateral sinuses of the dura mater, the laryngeal and pharyngeal veins. Both jugulars unite, and form with the subclavian vein, the superior vena cava, which terminates in the superior part of the right auricle of the heart.

JU′GULUM. (From *jugum,* a yoke; because the yoke is fastened to this part.) The throat, or anterior part of the neck.

JUJUBA. (An Arabian word.) Jujube. See *Rhamnus zizyphus.*

JU′JUBE. See *Rhamnus zizyphus.*

JULY-FLOWER. See *Dianthus Caryophyllus.*

JUNCKER, GOTTLOB, JOHN, was born in 1680 at Londorff, in Hesse. After the proper studies, he graduated at Halle in 1718; and became afterwards a distinguished professor there, as well as physician to the public hospital. His works, which are chiefly compilations, have been much esteemed, and are still occasionally referred to; especially as giving a compendious view of the doctrines of Stahl, which he espoused and taught. He has given a "Conspectus" of medicine, of surgery, of chemistry, and of several other departments of professional knowledge; also many academical theses on medical, chirurgical and philosophical subjects. He died in 1752.

JU′NCUS. (An old Latin word, a *jungendo,* say the etymologists, from the use of the plants which bear this name in joining or binding things together.) The name of a genus of plants in the Linnæan system. Class, *Hexandria;* Order, *Monogynia.*

JUNGUS ODORATUS. See *Andropogon schænanthus.*

JUNIPER. See *Juniperus communis.*

Juniper gum. See *Juniperus communis.*

JUNI′PERUS. (From *juvenis,* young, and *pario,* to bring forth: so called because it produces its young berries while the old ones are ripening.) 1. The name of a genus of plants. Class, *Dioecia;* Order, *Monodelphia.*

2. The pharmacopœial name of the common juniper. See *Juniperus communis.*

JUNIPERUS COMMUNIS. The systematic name of the juniper-tree. *Juniperus—foliis ternis patentibus mucronatis, baccis longioribus,* of Linnæus. Both the tops and berries of this indigenous plant are directed in our pharmacopœias, but the latter are usually preferred, and are brought chiefly from Holland and Italy. Of their efficacy as a stomachic, carminative, diaphoretic, and diuretic, there are several relations by physicians of great authority: and medical writers have also spoken of the utility of the juniper in nephritic cases, uterine obstructions, scorbutic affections, and some cutaneous diseases. Our pharmacopœias direct the essential oil, and a spirituous distillation of the berries, to be kept in the shops. From this tree is also obtained a concrete resin, which has been called sandarach, or gum juniper. It exudes in white tears, more transparent than mastich. It is almost totally soluble in alkohol, with which it forms a white varnish, that dries speedily. Reduced to powder it is called *pounce,* which prevents ink from sinking into paper from which the exterior coating of size has been scraped away.

JUNIPERUS LYCIA. The systematic name of the plant which affords the true frankincense. *Olibanum; Thus.* Frankincense, has received different appellations, according to its different appearances; the single tears are called simply *olibanum,* or *thus;* when two are joined together, *thus masculum;* and when two are very large, *thus femininum;* if several adhere to the bark, *thus corticosum;* the fine powder which rubs off from the tears, *mica thuris;* and the coarser *manna thuris.* The gum-resin that is so called, is the juice of the *Juniperus—foliis ternis undique imbricatis ovatis obtusis,* and is brought from Turkey and the East Indies; but that which comes from India is less esteemed. It is said to ooze spontaneously from the bark of the tree, appearing in drops, or tears, of a pale yellowish, and sometimes of a reddish colour. Olibanum has a moderately strong and not very agreeable smell, and a bitterish, somewhat pungent taste: in chewing, it sticks to the teeth, becomes white, and renders the saliva milky. Laid on a red-hot iron, it readily catches flame, and burns with a strong diffusive and not unpleasant smell. On trituration with water, the greatest part dissolves into a milky liquor, which, on standing, deposits a portion of resinous matter. The gummy and resinous parts are nearly in equal proportions; and though rectified spirit dissolves less of the olibanum than water, it extracts nearly all its active matter. In ancient times, olibanum seems to have been in great repute in affections of the head and breast, coughs, hæmoptysis, and in various fluxes, both uterine and intestinal; it was also much employed externally. Recourse is now seldom had to this medicine, which is superseded by myrrh, and other articles of the resinous kind. It is, however, esteemed by many as an adstringent, and though not in general use, is considered as a valuable medicine in fluor albus, and debilities of the stomach and intestines: applied externally in the form of plaster, it is said to be corroborant, &c. and with this intention it forms the basis of the *emplastrum thuris.*

JUNIPERUS SABINA. The systematic name of the common or barren savin-tree. *Sabina; Savina; Sabina sterilis; Brathu. Juniperus—foliis oppositis erectis decurrentibus, oppositionibus pyxidatis,* of Linnæus. Savin is a native of the south of Europe and the Levant; it has long been cultivated in our gardens, and from producing male and female flowers on separate plants, it was formerly distinguished into the barren and berry-bearing savin. The leaves and tops of this plant have a moderately strong smell of the disagreeable kind, and a hot, bitterish, acrid taste. They give out great part of their active matter to watery liquors, and the whole to rectified spirit. Distilled with water they yield a large quantity of essential oil. Decoctions of the leaves, freed from the volatile principle by inspissation to the consistence of an extract, retain a considerable share of their pungency and warmth along with their bitterness, and have some degree of smell, but not resembling that of the plant itself. On inspissating the spirituous tincture, there remains an extract consisting of two distinct substances, of which one is yellow, unctuous, or oily, bitterish, and very pungent; the other black, resinous, less pungent, and sub astringent. Savin is a powerful and active medicine, and has been long reputed the most efficacious in the materia medica, for producing a determination to the uterus, and thereby proving emmenagogue; it heats and stimulates the whole system very considerably, and is said to promote the fluid secretions. The power which this plant possesses (observes Dr. Woodville) in opening uterine obstructions, is considered to be so great, that we are told it has been frequently employed, and with too much success, for purposes the most infamous and unnatural. It seems probable, however, that its effects in this way have been somewhat over-rated, as it is found very frequently, to fail as an emmenagogue, though this, in some measure, may be ascribed to the smallness of the dose in which it has been usually prescribed by physicians; for Dr. Cullen observes, "that savin is a very acrid and heating substance, and I have been often, on account of these qualities, prevented from employing it in the quantity necessary to render it emmenagogue. I must own, however, that it shows a more powerful determination to the uterus than any other plant I have employed; but I have been frequently disappointed in this, and its heating qualities always require a great deal of caution." Dr. Home appears to have had very great success with this medicine, for in five cases of amenorrhœa, which occurred at the Royal Infirmary at Edinburgh, four were cured by the sabina, which he gave in powder from a scruple to a drachm twice a day. He says it is well suited to the debile, but improper in plethoric habits, and therefore orders repeated bleedings before its exhibition. Country people give the juice from the leaves and young tops of savin mixed with milk to their children, in order to destroy the worms; it generally operates by stool, and brings them away with it. The leaves cut small, and given to horses, mixed with their corn, destroy the bots. Externally savin is recommended as an escharotic to foul ulcers, syphilitic warts, &c. A strong decoction of the plant in lard and wax forms an useful ointment to keep up a constant discharge from blisters, &c. See *Ceratum sabinæ.*

JU'PITER. The ancient chemical name of tin, because supposed under the government of that planet.

JURIN, JAMES, was, during several years, an active member and Secretary of the Royal Society, and at his death in 1750, President of the College of Physicians. He distinguished himself by a series of seventeen dissertations, printed in the Philosophical Transactions, and afterwards as a separate work, in which mathematical science was applied with considerable acuteness to physiological subjects. These papers, however, involved him in several philosophical controversies concerning the force of the heart, &c. He was a warm advocate for the practice of inoculation, which he proved greatly to lessen the violence of the small-pox: but he did not anticipate that it would increase the mortality upon the whole, by keeping up the infection, while many retained their prejudices against adopting it.

JUSTICIA. (So named in honour of Mr. Justice, who published the British Gardener's Director.) The name of a genus of plants, Class, *Diandria;* Order, *Monogynia.*

JUVA'NTIA. (From *juvo*, to assist.) Whatever assists in relieving a disease.

JUVENTUS. See *Age.*

JUXTANGI'NA. (From *juxta*, near, and *angina*, a quinsy.) A disease resembling a quinsy.

K.

KAATH. See *Acacia catechu.*

KÆMPFER, ENGLEBERT, was born in 1651 at Lippe, in Westphalia. He was educated in Sweden, and being eager to travel, accompanied the Swedish Ambassador, Fabricius, to Persia, as secretary: on whose departure from Ispahan, after two years, he obtained the appointment of chief surgeon to the Dutch East India Company; and was thus enabled to penetrate as far as Siam and Japan, and cleared up the geography of these countries, which was very imperfectly known before. On his return to Europe, in 1694, he graduated at Leyden, and settled in his own country; he was afterwards appointed physician to his sovereign, and continued engaged in practice, and in composing several works, till his death, in 1716. In his Inaugural Dissertation, among other subjects relating to medicine, he notices a method of curing colic among the Japanese by puncture with a needle. But his great work, entitled "Amænitates Exoticæ," is more especially esteemed for its botanical information, and authentic details, relating to the history and manners of Persia, &c. His History of Japan, of which there is an English translation in folio, is highly valued for its accuracy and fidelity.

KÆMPFE'RIA. (Named after Kæmpfer, the Westphalian naturalist.) The name of a genus of plants. Class, *Monandria;* Order, *Monogynia.*

KÆMPFERIA GALANGA. The plant which affords the greater galangal root.

KÆMPFERIA ROTUNDA. The systematic name of the plant which affords the officinal zedoary. *Zedoaria. Kæmpferia—foliis lanceolatis petiolatis,* of Linnæus. The roots of this plant are brought to us in long pieces, *zedoaria longa,* about the thickness of the little finger, two or three inches in length, bent, rough, and angular; or in roundish pieces, *zedoaria rotunda,* about an inch in diameter, of an ash colour on the outside, and white within. They have an agreeable camphoraceous smell, and a bitterish aromatic taste. Though formerly much esteemed against rheumatic affections, they are at present thought to possess very little medicinal powers, although they had a place in the confectio aromatica of the London Pharmacopœia.

KA'JEPUT OLEUM. See *Melaleuca.*

KA'LI. (An Arabian word.) The vegetable alkali. See *Potassa.*

KALI ACETATUM. See *Potassæ acetas.*

KALI AERATUM. See *Potassæ carbonas.*

KALI ARSENICATUM. A preparation of arsenic, composed of the vegetable alkali and the acid of arsenic.

Kali citratum. See *Potassæ citras.*

Kali præparatum. See *Potassæ subcarbonas.*

Kali purum. See *Potassa fusa.*

Kali sulphuratum. See *Sulphuretum potassæ.*

Kali tartarizatum. See *Potassæ tartras.*

Kali vitriolatum. See *Potassæ sulphas.*

KARPHOLITE. A yellow mineral which occurs in thin prismatic concretions.

KEEL. See *Carina.*

Keeled leaf. See *Carinatus.*

KEILL, James, was born in Scotland, 1673. After going through the proper studies abroad, and especially attending to anatomy, he was enabled to lecture on that subject with great reputation in both the English universities, and received an honorary degree at Cambridge. During this period, he published a Compendium of Anatomy, chiefly from Cowper. In 1703, he settled in practice at Northampton; and three years after sent to the Royal Society an account of the dissection of a man, reputed to have been 130 years of age; which agreed very much with what Harvey found in old Parr. He was well skilled in mathematics, which he applied to the explanation of the laws of the animal economy. In 1708, he published "An Account of Animal Secretion, the Quantity of Blood in the Human Body, and Muscular Motion." To which, in a second edition, he added an Essay on the Force of the Heart. This engaged him in a controversy with Dr. Jurin, which was carried on in the Philosophical Transactions (Dr. Keill being then a member of the Royal Society) till the period of his premature death in 1719, occasioned by a cancer in the mouth, to which he had applied the cautery, but without any relief.

Kei'ri. See *Cheiranthus cheiri.*

KELP. Incinerated sea-weed.

KENEANGIA. (From κενος, empty, and αγγειον, a vessel.) 1. A state of inaction of the blood or other vessels.

2. A deficiency of blood in the vessels.

KERATE. The third mineral order of Mohs.

Kerato-pharyngæus. (From κερας, a horn, and φαρυγξ, the pharynx.) A muscle so named from its shape, and insertion in the pharynx.

KE'RMES. (*Chermah*, Arabian.) *Granum tinctorium; Coccus baphica.* Round reddish grains, about the size of peas, found in Spain, Italy, and the south of France, adhering to the branches of the scarlet oak. They are the nidus of a minute red animalcule, called *Coccus quercus ilicis.* The *confectio alkermes*, now obsolete, was prepared with these, which possess corroborant and adstringent virtues.

Kermes mineralis. A preparation of antimony, so termed from its resemblance in colour to the insect of that name. It is now disused in medicine, and gives place to the other preparations of antimony. See *Hydrosulphuretum stibii rubrum.*

KERNEL WORT. See *Scrophularia nodosa.*

Ke'rva. (*Kervah*, Arabian.) The *Ricinus communis.*

KETCHUP. The prepared liquor of the mushroom, made by sprinkling salt on that vegetable, and collecting the fluid which escapes.

Keyser's pills. A once celebrated mercurial medicine, the method of preparing which was purchased by the French government, and has since been published by Richard. The hydrargyrus acetatus is considered as an adequate substitute for the more elaborate form of Keyser. Richard concludes his account of Keyser's pills with observing, that he considers it to be, without exception, the most effectual remedy for the venereal disease hitherto discovered. But further trials of this remedy do not justify the sanguine accounts of its properties; though it may sometimes succeed when some of the other mercurial preparations have failed.

Kibes. A name for chilblains.

Kidria terrestris. Barbadoes tar.

KIDNEY. (*Ren, nis,* m.) An abdominal viscus, shaped like a kidney-bean, that secretes the urine. There are two kidneys. One is situated in each lumbar region, near the first lumbar vertebra, behind the peritonæum. This organ is composed of three substances; a cortical, which is external, and very vascular; a tubulous, which consists of small tubes; and a papillous substance, which is the innermost. The kidneys are generally surrounded with more or less adipose membrane, and they have also a proper membrane, *membrana propria*, which is closely accreted to the cortical substance. The renal arteries, called also emulgents, proceed from the aorta. The veins evacuate their blood into the ascending cava. The absorbents accompany the blood-vessels, and terminate in the thoracic duct. The nerves of the kidneys are branches of the eighth pair and great intercostal. The excretory duct of this viscus is called the *ureter.* At the middle of the kidney, where the blood-vessels enter it, is a large membraneous bag, called the pelvis, which diminishes like a funnel, and forms a long canal, the ureter, that conveys the urine from the kidney to the bladder, which it perforates obliquely.

Kidney-shaped leaf. See *Reniformis.*

KIFFEKILL. See *Meerschaum.*

Kikekunemalo. A pure resin, very similar to copal, but of a more beautiful whiteness and transparency. It is brought from America, where it is said to be used medicinally, in the cure of hysteria, tetanus, &c. It forms the most beautiful of all varnishes.

Ki'ki. (*Kike*, Arabian.) See *Ricinus.*

Ki'na kina. See *Cinchona.*

KINATE. *Kinas.* A compound of the Kinic acid, with a salifiable base.

KINIC ACID. (*Acidum kinicum;* from *kinia*, the French name of *cinchona*, from which it is obtained.) "A peculiar acid extracted from cinchona. Let a watery extract from hot infusions of the bark in powder be made. Alkohol removes the resinous part of this extract, and leaves a viscid residue, of a brown colour, which has hardly any bitter taste, and which consists of kinate of lime and a mucilaginous matter. This residue is dissolved in water, the liquor is filtered and left to spontaneous evaporation in a warm place. It becomes thick like syrup, and then deposits by degrees crystalline plates, sometimes hexaëdral, sometimes rhomboidal, sometimes square, and always coloured slightly of a reddish-brown. These plates of kinate of lime must be purified by a second crystallisation. They are then dissolved in ten or twelve times their weight of water, and very dilute aqueous oxalic acid is poured into the solution, till no more precipitate is formed. By filtration, the oxalate of lime is separated, and the kinic acid being concentrated by spontaneous evaporation, yields regular crystals. It is decomposed by heat. While it forms a soluble salt with lime, it does not precipitate lead or silver from their solutions. These are characters sufficiently distinctive. The kinates are scarcely known; that of lime constitutes seven per cent. of *cinchona.*"

Kinki'na. See *Cinchona.*

KINO. (An Indian word.) *Gummi gambiense; Gummi rubrum adstringens gambiense.* The tree from which this resin is obtained, though not botanically ascertained, is known to grow on the banks of the river Gambia, in Africa. On wounding its bark, the fluid kino immediately issues drop by drop, and, by the heat of the sun, is formed into hard masses. It is in appearance very like the resin called *Sanguis draconis;* much redder, more firm, resinous, and adstringent than catechu. It is now in common use, and is one of the most efficacious vegetable adstringents, or styptics, in the materia medica. Its dose is from twenty to thirty grains.

KNEE-HOLLY. See *Ruscus.*

KNEE-PAN. See *Patella.*

KOLLYRITE. A light greasy mineral of a white colour, which adheres to the tongue.

Kolto. (A Polonese word.) The plica polonica, or plaited hair.

KOUMIS. A vinous liquid which the Tartars make by fermenting mares' milk. Something similar is prepared in the Orkneys and Shetland.

KRAMERIA. (So named in commemoration of two German botanists, who flourished about the middle of the last century.) The name of a genus of plants in the Linnæan system. Class, *Tetrandria;* Order, *Monogynia.*

Krameria triandria. The systematic name of the tree, the root of which is called *rhatania,* a substance which has been long known to the manufacturers of port wine; it is the production of Peru, and was long thought to be the root of the cinchona cordifolia. It is described as externally resembling the root of the rubia tinctorum to the taste, being aromatic, bitter, and very astringent: its infusion or decoction turns black with sulphate of iron, and precipitates tannin. The principal virtues appear to reside in the cortical part of the root, which is thick and resinous. An opinion prevails that the substance sold in the shops under the name of foreign extract of bark is made from this root.

It is well known that the medical virtues of this root are powerfully tonic. In debility of the digestive organs, in chronic rheumatism, fluor albus, and in intermittent fevers, it has been employed with good effect. While given in doses similar to cinchona, it has the advantage of being only one-third the price of that substance.

KRAMERIC ACID. (*Acidum kramericum;* from *krameria,* the name of the plant from which it is obtained.) An acid obtained by Peschier from the root of the *Krameria triandria.*

Kyanite. See *Cyanite.*

Kyna'nche. See *Cynanche.*

L.

LA'BDANUM. See *Cistus creticus.*

LABELLUM. A little lip. Applied in botany to the barba, or inferior lip of ringent and personate plants. See *Corolla.*

LABIUM. (*Labium, i.* n.; *απο του λαβειν.*)

1. The lip of animals.

2. Applied in botany to corolls of plants, which are termed *unilabiate, bilabiate,* &c. and from their position in certain flowers, *superior, inferior,* &c.

La'bium leporinum. See *Hare-lip.*

LABORATO'RIUM. (From *laboro,* to labour.) A place properly fitted up for the performance of chemical operations.

LABRADOR STONE. See *Felspar.*

LA'BYRINTH. *Labyrinthus.* That part of the internal ear which is behind the cavity of the tympanum; it is constituted by the cochlea, vestibulum, and semicircular canals. See *Ear.*

LAC. (*Lac, tis.* n.) 1. Milk. See *Milk.*

2. The name of a vegetable substance. See *Lacca.*

Lac ammoniaci. See *Mistura ammoniaci.*

Lac amygdalæ. See *Mistura amygdalæ.*

Lac assafœtidæ. See *Mistura assafœtidæ.*

Lac sulphuris. See *Sulphur præcipitatum.*

LA'CCA. (From *lakah,* Arabian.) *Gummi laccæ.* Stic-lac; Gum-lac; Seed-lac; Shell-lac. The improper name of gum-lac is given to a concrete brittle substance, of a dark red colour, brought from the East Indies, incrustated on the twigs of the *Croton lacciferum; foliis ovatis tomentosis serrulatis petiolatis, calycibus tomentosis,* of Linnæus, where it is deposited by a small insect, at present not scientifically known. It is found in very great quantities on the uncultivated mountains on both sides the Ganges: and is of great use to the natives in various works of art, as varnish, painting, dyeing, &c. When the resinous matter is broken off the wood into small pieces or grains, it is termed *seed-lac,* and when melted and formed into flat plates, *shell-lac.* This substance is chiefly employed for making sealing-wax. A tincture of it is recommended as an antiscorbutic to wash the gums.

LA'CHRYMA. A tear. A limpid fluid secreted by the lachrymal gland, and flowing on the surface of the eye. See *Tear.*

Lachryma abiegna. See *Terebinthina argentoratensis.*

LACHRYMAL. *Lachrymalis.* Of or belonging to tears or parts near where they are secreted.

Lachrymal bone. See *Unguis os.*

Lachrymal duct. *Ductus lachrymalis.* The excretory duct of the lachrymal gland, which opens upon the internal surface of the upper eyelid.

Lachrymal gland. *Glandula lachrymalis.* A glomerate gland, situated above the external angle of the orbit, in a peculiar depression of the frontal bone. It secretes the tears, and conveys them to the eye by its excretory ducts, which are six or eight in number.

Lachrymal nerve. The fifth pair of nerves from the head is divided into several branches, the first of which is called the orbitary branch; this is divided into three more, the third of which is called the *lachrymal branch;* it goes off chiefly to the lachrymal gland.

LACCIC ACID. (*Acidum laccicum;* from *lacca,* the substance in which it exists.) "Dr. John made a watery extract of powdered stick lac, and evaporated it to dryness. He digested alkohol on this extract, and evaporated the alkoholic extract to dryness. He then digested this mass in æther, and evaporated the ethereal solution; when he obtained a syrupy mass of a light yellow colour, which was again dissolved in alkohol. On adding water to this solution, a little resin fell. A peculiar acid united to potassa and lime remains in the solution, which is obtained free, by forming with acetate of lead an insoluble laccate, and decomposing this with the equivalent quantity of sulphuric acid. Laccic acid crystallises; it has a wine-yellow colour, a sour taste, and is soluble, as we have seen, in water, akohol, and æther. It precipitates lead and mercury white; but it does not affect lime, barytes, or silver, in their solutions. It throws down the salts of iron white. With lime, soda, and potassa, it forms deliquescent salts, soluble in alkohol."

LACINIATUS. Laciniate, fringe-like; cut into numerous irregular portions: applied to leaves, petals, &c; as the leaves of the *Ranunculus parviflorus*, and *Geranium columbinum*, the petals of the *Reseda*.

LACO'NICUM. (Because they were much used by the people of Laconia.) A stove or sweating-room.

LACQUER. A solution of lac in alkohol.

LACTATE. *Lactas.* A definite compound formed by the union of the acid of sour whey, or lactic acid, with salifiable bases; thus lactate of potassa, &c.

LACTATION. (*Lactatio;* from *lacteo,* to suckle.) The giving suck.

LACTEAL. (*Lacteus;* from *lac,* milk; because the fluid they absorb looks like milk.)

1. Milky.

2. In anatomy this term is applied to the *vasa lactea.* The absorbents of the mysentery, which originate in the small intestines, and convey the chyle from thence to the thoracic duct. They are very tender and transparent vessels, possessed of an infinite number of valves, which, when distended with chyle, a milky or lacteal fluid, give them a knotty appearance. They arise from the internal surface of the villous coat of the small intestine, perforate the other coats, and form a kind of net-work, whilst the greater number unite one with another between the muscular and external coats. From thence they proceed between the laminæ of the mesentery to the conglobate glands. In their course they constitute the greater part of the gland through which they pass, being distributed through them several times, and curled in various directions. The lacteals having passed these glands, go to others, and at length seek those nearest the mesentery. From these glands, which are only four or five, or perhaps more, the lacteals pass out and ascend with the mesenteric artery, and unite with the lymphatics of the lower extremities, and those of the abdominal viscera, and then form a common trunk, the *thoracic duct,* which, in some subjects, is dilated at its origin, forming the *receptaculum chyli.* See *Nutrition.*

LACTESCENS. (From *lac,* milk.) Lactescent or milky.

LACTIC ACID. (*Acidum lacticum;* from *lac,* milk.) "By evaporating sour whey to one-eighth, filtering, precipitating with lime water, and separating the lime by oxalic acid, Scheele obtained an aqueous solution of what he supposed to be a peculiar acid, which has accordingly been termed the *lactic.* To procure it separate, he evaporated the solution to the consistence of honey, poured on it alkohol, filtered this solution, and evaporated the alkohol. The residuum was an acid of a yellow colour, incapable of being crystallised, attracting the humidity of the air, and forming deliquescent salts with the earths and alkalies.

Bouillon Lagrange since examined it more narrowly; and from a series of experiments concluded, that it consists of acetic acid, muriate of potassa, a small portion of iron probably dissolved in the acetic acid, and an animal matter.

This judgment of Lagrange was afterwards supported by the opinions of Fourcroy and Vauquelin. But since then Berzelius has investigated its nature very fully, and has obtained, by means of a long and often repeated series of different experiments, a complete conviction that Scheele was in the right, and that the lactic acid is a peculiar acid, very distinct from all others.

The lactic acid, purified, has a brown-yellow colour, and a sharp sour taste, which is much weakened by diluting it with water. It is without smell in the cold, but emits, when heated, a sharp sour smell, not unlike that of sublimed oxalic acid. It cannot be made to crystallise, and does not exhibit the slightest appearance of a saline substance, but dries into a thick and smooth varnish, which slowly attracts moisture from the air. It is very easily soluble in alkohol. Heated in a gold spoon over the flame of a candle, it first boils, and then its pungent acid smell becomes very manifest, but extremely distinct from that of the acetic acid; afterwards it is charred, and has an empyreumatic, but by no means an animal smell. A porous charcoal is left behind, which does not readily burn to ashes. When distilled, it gives an empyreumatic oil, water, empyreumatic vinegar, carbonic acid, and inflammable gases. With alkalies, earths, and metallic oxides, it affords peculiar salts; and these are distinguished by being soluble in alkohol, and in general by not having the least disposition to crystallise, but drying into a mass like gum, which slowly becomes moist in the air."

LA'CTICA. The Arabian name for the fever which the Greeks call *Typhos.*

LACTI'FUGA. (From *lac,* milk, and *fugo,* to drive away.) A medicine or other means which dispel milk.

LACTU'CA. (From *lac,* milk: named from the milky juice which exudes upon its being wounded.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Polygamia æqualis.* The lettuce.

2. The pharmacopœial name of the garden-lettuce, the *Lactuca sativa.*

LACTUCA GRAVEOLENS. See *Lactuca virosa.*

LACTUCA SATIVA. The systematic name of the lettuce. It is esteemed as a wholesome aperient bitter anodyne, easy of digestion, but affording no nutriment. Lettuces appear to agree better with hot, bilious melancholic temperaments, than the phlegmatic. The seeds possess a quantity of oily substance, which, triturated with water, forms an emulsion esteemed by some in ardor urinæ, and some diseases of the urinary passages. Lettuce was famous for the cure of the Emperor Augustus, and formed the opiate of Galen, in his old age; a proof that, in the warmer climates, it must acquire an exaltation of its virtues above what is met with in this country.

LACTUCA SCARIOLA. *Lactuca sylvestris: Scariola; Scariola gallorum.* This species possesses a stronger degree of bitterness than the *Lactuca sativa,* and is said to be more aperient and laxative. It is nearly similar, in virtue as in taste, to endive unblanched.

LACTUCA SYLVESTRIS. See *Lactuca scariola.*

LACTUCA VIROSA. The systematic name of the opium, or strong-scented lettuce. *Lactuca graveolens. Lactuca—foliis horizontalibus carino aculeatis dentatis*, of Linnæus. A common plant in our hedges and ditches. It has a strong ungrateful smell, resembling that of opium, and a bitterish acrid taste: it abounds with a milky juice, in which its sensible qualities seem to reside, and which appears to have been noticed by Dioscorides, who describes the odour and taste of the juice as nearly agreeing with that of the white poppy. Its effects are also said, according to Haller, to be powerfully narcotic. Dr. Collin, at Vienna, first brought the lactuca virosa into medical repute, and its character has lately induced the College of Physicians at Edinburgh, to insert it in the catalogue of the materia medica. More than twenty-four cases of dropsy are said, by Collin, to have been successfully treated by employing an extract prepared from the expressed juice of this plant, which is stated not only to be powerfully diuretic, but, by attenuating the viscid humours to promote all the secretions, and to remove visceral obstructions. In the more simple cases, proceeding from debility, the extract, in doses of eighteen to thirty grains a day, proved sufficient to accomplish a cure; but when the disease was inveterate, and accompanied with visceral obstructions, the quantity of extract was increased to three drachms; nor did larger doses, though they excited nausea, ever produce any other bad effect; and the patients continued so strong under the use of this remedy, that it was seldom necessary to employ any tonic medicines. Though Dr. Collin began his experiments with the lactuca at the Pazman hospital, at the time he was trying the arnica, 1771, yet very few physicians, even at Vienna, have since adopted the use of this plant. Plenciz, indeed, has published a solitary instance of its efficacy, while Quarin informs us that he never experienced any good effect from its use; alleging, that those who were desirous of supporting its character, mixed it with a quantity of extractum scillæ. Under these circumstances we shall only say, that the recommendation of this medicine by Dr. Collin, will be scarcely thought sufficient to establish its use in England.

LACTUCE'LLA. (Diminutive of *lactuca*, the lettuce: so named from its milky juice.) The sow-thistle. The *Sonchus arvensis*.

LACTUCI'MINA. (From *lacteo*, to suckle: so called because they happen chiefly to children while at the breast.) The thrush, and little ulcers, or crusty scabs on the skin, which happen during the time the child is at the breast.

LACTU'MEN. (From *lac*, milk; so named because it is covered with a white crust.) The achor, or scald-head; also a little crusty scab on the skin, affecting children at the breast.

LACU'NA. (From *lacus*, a channel.) The mouth or opening of the excretory duct of a muciparous gland, as those of the urethra, and other parts.

LA'DANUM. (From *ladon*, Arab.) See *Cistus creticus*.

Ladies' bedstraw. See *Galium*.

Ladies' mantle. See *Alchemilla*.

Ladies' smock. See *Cardamine*.

LÆTIFICA'NTIA. (From *lætifico*, to make glad.) This term hath been applied to many compositions under the intention of cordials; but both the medicines and distinction are now quite disused.

LÆVIS. Smooth and even. Applied to stems of plants, and is opposed to all roughness and inequality whatever.

LÆVITAS INTESTINORUM. A name of the lientery. See *Diarrhœa*.

LA'GAROS. (Λαγαρος, lax: so named from its comparative laxity.) The right ventricle of the heart.

LAGENÆFORMIS. Bottle-shaped. Applied to the gourd; as in *Cucurbita lagenaria*.

LAGNESIS. (From λαγνης, libidinous.) The name of a genus of diseases. Class, *Genetica*; Order, *Orgastica*; in Good's Nosology: lust. It embraces two species, viz. *Lagnesis salacitas* and *L. furor*.

LAGOPHTHA'LMIA. (From λαγωος, a hare, and οφθαλμος, an eye; because it is believed that hares sleep with their eyes open.) *Lagophthalmos*. The hare's eye. A disease in which the eye cannot be shut. The following complaints may arise from it: a constant weeping of the organ, in consequence of the interruption of the alternate closure and opening of the eye-lids, which motions so materially contribute to propelling the tears into the nose; blindness in a strong light, in consequence of the inability to moderate the rays which fall on the eye; on the same account, the sight becomes gradually very much weakened; incapacity to sleep where there is any light; irritation, pain, and redness of the eye, from this organ being exposed to the extraneous substances in the atmosphere, without the eye-lids having the power of washing them away in the natural manner.

An enlargement or protrusion of the whole eye, or a staphyloma, may obviously produce lagophthalmos. But affections of the upper eye-lids are the common causes. Heister says he has seen the complaint originate from a disease of the lower one. Now and then lagophthalmos depends on paralysis of the orbicularis muscle. A cicatrix after a wound, ulcer, or burn, is the most frequent cause.

LAGOPO'DIUM. (From λαγωος, a hare, and πους, a foot: so called because it has narrow hairy leaves, like the foot of a hare.) The herb hare's-foot trefoil.

LAGO'STOMA. (From λαγωος, a hare, and ϛομα, the mouth: so called because the upper lip is divided in the middle like that of a hare.) See *hare-lip*.

LAKEWEED. See *Polygonum hydropiper*.

LALLANS. See *Lallatio*.

LALLATIO. That species of vicious pronunciation in which the letter *l* is rendered unduly liquid, or substituted for an *r*. The Greeks denominated it *lambdacismus*, from the letter λ, *lambda*.

LA'MAC. Gum-arabic.

LAMBDACI'SMUS. A defect in speech, which consists in an inability to pronounce certain consonants; or that stammering or difficulty of speech when the letter *l* is pronounced too liquid, and often in the place of *r*. See *Psellismus lallans*.

LAMBDOIDAL. (*Lambdoidalis*; from Λ, and ειοδος, resemblance, because it is shaped like the letter Λ.) Belonging to the suture so called.

LAMBDOIDAL SUTURE. (*Sutura lambdoidalis*; because it is shaped like the letter Λ.) Occipital suture. The suture that unites the occipital bone to the two parietal bones.

LAMBITIVUM. (From *lambo*, to lick up.) A linctus or medicine to be licked up.)

LAME'LLA. (Dim. of *lamina*, a plate of metal.) 1. A thin plate of metal.

2. The parallel gills or plates in the inferior surface of the agaric family only.

LA'MINA. (From ελαω, to beat off.) A bone, or membrane, or any substance resembling a thin plate of metal.

2. The lap of the ear.

3. The parts of the corolla of a polypetalous flower, are named the *unguis*, or claw, and *lamina*, or border.

LAMINABILITY. A property possessed by some bodies of being extended in dimensions by a gradually applied pressure. See *Ductility*.

LA'MIUM. (From *Lamium*, a mountain of Ionia, where it grew; or from *lama*, a ditch, because it usually grows about ditches and neglected places.) The name of a genus of plants in the Linnæan system. Class, *Didynamia;* Order, *Gymnospermia.* The nettle.

LAMIUM ALBUM. *Urtica mortua; Archangelica; Galeobdolon; Stachys fœtida; Urtica iners magna fœtidissima.* Dead nettle; White archangel nettle. Uterine hæmorrhages and fluor albus are said to be relieved by infusions of this plant, from whose sensible qualities very little benefit can be expected.

LAMPIC ACID. (*Acidum lampsicum;* from λαμπω, to shine.) "Sir H. Davy, during his admirable researches on the nature and properties of flame, announced the singular fact, that combustible bodies might be made to combine rapidly with oxygen, at temperatures below what were necessary to their *visible* inflammation. Among the phenomena resulting from these new combinations, he remarked the production of a peculiar acid and pungent vapour from the slow combustion of æther; and from its obvious qualities he was led to suspect, that it might be a product yet new to the chemical catalogue. Faraday, in the 3d volume of the Journal of Science and the Arts, has given some account of the properties of this new acid; but from the very small quantities in which he was able to collect it, was prevented from performing any decisive experiments upon it.

In the 6th volume of the same Journal, we have a pretty copious investigation of the properties and compounds of this new acid, by Daniell. From the slow combustion of æther during six weeks, by means of a coil of platina wire sitting on the cotton wick of the lamp, he condensed with the head of an alembic, whose beak was inserted in a receiver, a pint and a half of the lampic acid liquor.

When first collected it is a colourless fluid of an intensely sour taste, and pungent odour. Its vapour, when heated, is extremely irritating and disagreeable, and when received into the lungs, produces an oppression at the chest, very much resembling the effect of chlorine. Its specific gravity varies according to the care with which it has been prepared, from less than 1.000 to 1.008. It may be purified, by careful evaporation; and it is worthy of remark, that the vapour which rises from it is that of alkohol, with which it is slightly contaminated, and not of æther. Thus rectified, its specific gravity is 1.015. It reddens vegetable blues, and decomposes all the earthy and alkaline carbonates, forming neutral salts with their bases, which are more or less deliquescent."—*Ure's Chem. Dict.*

LA'MPSANA. See *Lapsana.*

LANA. Wool. In botany applied to a species of hairy pubescence, consisting of white, long, somewhat crisp hair, like wool. It is applied to stems, leaves, seeds, &c.

LANA PHILOSOPHICA. The snowy flakes of white oxide which rise and float in the air from the combustion of zinc.

LANATUS. Woolly. Applied to the stems, leaves, seeds, &c. of plants. The Verbascum thapsus is a good example of the *Caulis lanatus;* the Stachys lanata of the leaves; and the Gossypium of the seed.

LANCEOLATUS. Lanceolate, lance-shaped. Applied to leaves, petals, seeds, &c. of a narrow oblong form, tapering towards each end; as the *leaves* in Plantago lanceolata, and *petals* of Narcissus minor, and *seeds* of the Fraxinus.

LANCE'TTA. (Dim. of *lancea*, a spear.) A lancet. An instrument used for bleeding and other purposes.

LANCISI, JOHN MARIA, was born at Rome in 1654. He was intended for the church, but a taste for natural history led him to the study of medicine, which he pursued with great ardour, and took his degree at the age of 18. After some minor appointments, which enabled him to display his talents and acquirements, he was appointed professor of anatomy in 1684; and continued his duties for 13 years with great reputation. He was made physician to three succeeding popes, and attained the age of 65. He had great knowledge of mankind, with very engaging manners; and his zeal for the advancement of medicine was extreme and unceasing. He collected a library of above 20,000 volumes, which he devoted to the use of the public, and particularly of medical students: it was opened four years before his death. He left a considerable number of works, several of which were printed, others remain in manuscript in that library. His more important publications are, a treatise "De Subitaneis Mortibus;" "The Anatomical plates of Eustachius, with a preface and notes, in folio;" and a dissertation, "De Noxiis Paludum Effluviis," referring intermittents to the Marsh Miasmata, printed in 1717. After his death, a treatise "De Motu Cordis et Aneurysmatibus," and a collection of cases from his manuscript, were given to the public.

LANGRISH, BROWNE, a physician of the last century, distinguished himself as an advocate for the mechanical theories of physiology and medicine, which he supported by numerous experiments. He had the merit of ascertaining several interesting facts in respect to the nature of the circulating powers. He died in London in 1759. His publications are, "A New Essay on Muscular Motion, &c." "Modern Theory of Physic;" "Physical Experiments upon Brutes;" and "Croonian Lectures on Muscular Motion."

LAO'NICA CURATIO. A method of curing the gout, by evaporating the morbid matter by topical applications.

LAPA'CTICA. (From λαπαζω, to evacuate.) Purgative medicines.

LA'PARA. (From λαπαζω, to empty; so named from its concave and empty appearance.) The flank.

LAPAROCE'LE. (From λαπαρα, the flank, and κηλη, a rupture.) A rupture through the side of the belly.

LA'PATHUM. (From λαπαζω, to evacuate: so named because it purges gently.) The dock. See *Rumex.*

LAPATHUM ACETOSUM. See *Rumex acetosa.*

LAPATHUM ACUTUM. See *Rumex acutus.*

LAPATHUM AQUATICUM. See *Rumex hydrolapathum.*

LAPIDE'LLUM. (From *lapis*, a stone.) *Lapidellus.* The name of a kind of spoon, formerly used to take out small stones and fragments from the bladder.

LAPIDEUS. Stony. Applied to seeds of plants; as those of the *Lithospermum* and *Osteosperma.*

La'pides cancrorum. See *Cancer.*

Lapi'lli cancrorum. See *Cancer.*

LA'PIS. (*Lapis, idis.* m.; of uncertain derivation.) A stone.

Lapis ageratus. See *Ageratus.*

Lapis bezoar. See *Bezoar.*

Lapis cæruleus. See *Lapis lazuli.*

Lapis calaminaris. See *Calamine.*

Lapis calcareus. A carbonate of lime.

Lapis cyanus. See *Lapis lazuli.*

Lapis hæmatites. See *Hæmatites.*

Lapis hibernicus. *Tegula hibernica. Ardesia hibernica. Hardesia.* Irish slate. A kind of slate, or very hard stone, found in different parts of Ireland, in a mass of a bluish black colour, which stains the hands. When dried and powdered, it is pale, or of a whitish blue, and, by keeping, grows black. In the fire it yields a sulphureous gas, and acquires a pale red colour, with additional hardness. It is occasionally powdered by the common people, and taken in spruce beer, against inward bruises.

Lapis hystricis. See *Bezoar hystricis.*

Lapis infernalis. An old name for the caustic potassa. See *Potassa fusa.*

Lapis lazuli. *Lapis cyanus.* Azure stone. A combination of 46 silica, 28 lime, 14.5 alumina, 3 oxide of iron, 6.5 sulphate of lime, and 2 water, according to Klaproth. This singular mixture forms a stone, of a beautiful azure blue, which it preserves in a strong heat, and does not suffer any alteration by the contact of air. The finest specimens come from China, Persia, and Great Bucharia. It was formely exhibited as a purgative and vomit, and given in epilepsy.

Lapis malacensis. See *Bezoar hystricis.*

Lapis ollaris. Potstone.

Lapis porcinus. See *Bezoar hystricis.*

Lapis simiæ. See *Bezoar simiæ.*

LAPPA. (*Lappa* απο τȣ λαβειν, from its seizing the garments of passengers.) See *Arctium lappa.*

Lappa major. See *Arctium lappa.*

LA'PSANA. (Λαψανη, from *Lampsacus*, the town near which it flourished: or from λαπαζω, to evacuate; because it was said to relax the bowels.) The name of a genus of plants. Class, *Syngenesia*; Order, *Polygamia æquales.*

Lapsana communis. *Lampsana; Napium; Papillaris herba.* Dock-cresses. Nipple-wort. This plant is a lactescent bitter, and nearly similar in virtues to the cichory, dandelion, and endive. It has been employed chiefly for external purposes, against wounds and ulcerations, whence the name of nipple-wort and papillaris.

La'queus gutturis. A malignant inflammation of the tonsils, in which the patient appears as if he were suffocated with a noose.

La'rbason. Antimony.

LARCH. See *Pinus larix.*

LARD. The English name of hog's fat, when melted down. See *Adeps suilla.*

LARYNGISMUS. The name of a genus of diseases. Class, *Pneumatica*; Order, *Pneumonica*, in Good's Nosology. Laryngic suffocation. It has only one species, *stridulus*, the spasmodic croup.

LARYNGOTOMY. (*Laryngotomia*; from λαρυγξ, the larynx, and τεμνω, to cut.) See *Bronchotomy.*

LARYNX. (*Larynx, gis.* f.; a Greek primitive.) A cartilaginous cavity, situated behind the tongue, in the anterior part of the fauces, and lined with an exquisitely sensible membrane. It is composed of the annular or cricoid cartilage, the scutiform or thyroid, the epiglottis and two arytænoid cartilages. The superior opening of the larynx is called the *glottis.* The *laryngeal arteries* are branches of the external carotids. The *laryngeal veins*, evacuate their blood into the external jugulars. The nerves of the larynx are from the eighth pair. The use of the larynx is to constitute the organ of voice, and to serve also for respiration.

LASCI'VUS. (From *lacio*, to ensnare; upon account of its irregular motions.)

1. Lascivious.

2. An epithet used by Paracelsus for the chorea sancti viti.

LA'SER. (A term used by the Cyrenians.) The herb laser-wort, or assafœtida.

LASERPI'TIUM. (*Lac serpitium*, alluding to its milky juice.) The name of a genus of plants in the Linnæan system: Class, *Pentandria*; Order, *Digynia.*

Laserpitium chironium. *Panax.* Hercules' allheal, or wound-wort. The seeds and roots of this plant are warm, and similar in flavour and quality to those of the parsnep. The roots and stalks have a much stronger smell, which resembles that of opoponax; and Boerhaave relates, that on wounding the plant in the summer, he obtained a yellow juice, which, being inspissated a little in the sun, agreed perfectly in both respects with that exotic gum resin.

Laserpitium latifolium. The systematic name of the white gentian. *Gentiana alba.* The root of this plant, *Laserpitium foliis cordatis, inciso-serratis*, of Linnæus, possesses stomachic, corroborant, and deobstruent virtues. It is seldom used.

Laserpitium siler. The systematic name of the heart-wort. *Seseli*; *Siler montanum.* Sermountain. The seeds and roots of this plant, which grows in the southern parts of Europe, are directed as officinals. They have an agreeable smell, and a warm, glowing, aromatic taste; and though neglected in this country, do not appear to be deservedly so.

LATERAL. (*Lateralis*; from *latus*, the side.) On the side. A term in general use, applied to parts of the body, operations, and to flower-stalks when situated on the side of a stem or stalk; as in *Erica vagans.*

Lateral operation. A name given to an operation. One mode of cutting for the stone, because it is performed on the side of the pelvis. See *Lithotomy.*

Lateral sinus. See *Sinus.*

LATERITIOUS. (*Lateritius*; from *later*, a brick.) A term applied to the brick-like sediment occasionally deposited in the urine of people afflicted with fever.

LA'TEX. (*Latex, quod in venis terræ lateat.*) Water, or juice. A term sometimes applied to the blood, as being the spring or source of all the humours.

La'thyris. (From λαθω, to forget; because it was thought to affect the memory.) A term given by some author, to a species of tithymal or spurge, commonly known by the name of *Tithymalus latifolius*, the broad-leaved spurge, and called by some also *Cataputia.*

LA'THYRUS. (A name adopted from Theophrastus, whose λαθυμος, appears evidently to be like ours, something of the pea or vetch kind, though it is impossible precisely to determine what.) The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria.* The vetch.

Lati'bulum. (From *lateo*, to lie hid.) The fomes, or hidden matter of infectious diseases.

LATI'SSIMUS. A term applied to a muscle from its great breadth.

LATISSIMUS COLLI. See *Platysma myoides*.

LATISSIMUS DORSI. *Aniscalptor*, of Cowper. *Dorsi-lumbo sacro humeral*, of Dumas. A muscle of the humerus, situated on the posterior part of the trunk. It is a very broad, thin, and, for the most part, fleshy muscle, which is placed immediately under the skin, except where it is covered by the lower extremity of the trapezius. It arises tendinous from the posterior half of the upper edge of the spine of the os ilium, from the spinous processes of the os sacrum and lumbar vertebræ, and from five or six, and sometimes from seven, and even eight, of the lowermost ones of the back; also tendinous and fleshy from the upper edges and external surface of the four inferior false ribs, near their cartilages, by as many distinct slips. From these different origins the fibres of the muscle run in different directions; those from the ilium and false ribs run almost perpendicularly upwards; those from the sacrum and lumbar vertebræ, obliquely upwards and forwards; and those from the vertebræ of the back, transversely outwards and forwards, over the inferior angle of the scapula, where they receive a small thin bundle of fleshy fibres, which arise tendinous from that angle, and are inserted with the rest of the muscle, by a strong, flat, and thin tendon, of about two inches in length, into the fore-part of the posterior edge of the groove observed between the two tuberosities of the os humeri, for lodging the tendon of the long head of the biceps. In dissection, therefore, this muscle ought not to be followed to its insertion, till some of the other muscles of the os humeri have been first raised. Its use is to pull the os humeri downwards and backwards, and to turn it upon its axis. Riolanus, from its use on certain occasions, gave it the name of *ani tersor*. When we raise ourselves upon our hands, as in rising from off an arm-chair, we may easily perceive the contraction of this muscle. A *bursa mucosa* is found between the tendon of this muscle and the os humeri, into which it is inserted.

LAUCA'NIA. (From λαυω, to receive: so called because it receives and conveys food.) The œsophagus.

LAU'DANUM. (From *laus*, praise; so named from its valuable properties.) See *Tinctura opii*.

LAUMONITE. Diprismatic zeolite.

LAUREL. See *Laurus*.

Laurel, cherry. See *Prunus laurocerasus*.

Laurel, spurge. See *Daphne laureola*.

LAURE'OLA. (Dim. of *laurus*, the laurel; named from its resemblance to the laurel.) See *Daphne laureola*.

LAURO-CERASUS. (From *laurus*, the laurel, and *cerasus*, the cherry-tree; so called because it has leaves like the laurel.) See *Prunus laurocerasus*.

LAURO'SIS. (So called from Mount Laurus, where there were silver mines.) The spodium of silver.

LAU'RUS. (From *laus*, praise; because it was usual to crown the heads of eminent men with branches of it.) 1. The name of a genus of plants in the Linnæan system. Class, *Enneandria*; Order, *Monogynia*. The laurel.

2 The pharmacopœial name of the sweet-bay. See *Laurus nobilis*.

LAURUS CAMPHORA. The systematic name of the camphire-tree. *Laurus—foliis triplinerviis lanceolato-ovatis*. It affords the substance called *Camphora*; *Camphura*; *Caf*; *Cafar*; *Ligatura veneris*; *Caphora*, *Capur*; *Alkosor*; *Altesor*. Camphire, or camphor is a peculiar concrete substance prepared by distillation. The tree is indigenous and grows abundantly. The camphire is found to lodge every where in the interstices of the fibres of the wood, pith, and knots of the tree. The crude camphire, exported from Japan, appears in small greyish pieces, and is intermixed with various extraneous matters; in this state it is received by the Dutch, and purified by a second sublimation; it is then formed into loaves, in which state it is sent to England.

"Purified camphor is a white concrete crystalline substance, not brittle, but easily crumbled, having a peculiar consistence resembling that of spermaceti, but harder. It has a strong lively smell, and an acrid taste; is so volatile as totally to exhale when left exposed in a warm air; is light enough to swim on water; and is very inflammable, burning with a very white flame and smoke, without any residue.

The roots of zedoary, thyme, rosemary, sage, the inula hellenium, the anemone, the pasque flower or pulsatilla, and other vegetables, afford camphor by distillation. It is observable, that all these plants afford a much larger quantity of camphor, when the sap has been suffered to pass to the concrete state by several months' drying. Thyme and peppermint, slowly dried, afford much camphor; and Achard has observed that a smell of camphor is disengaged when volatile oil of fennel is treated with acids.

Kind, a German chemist, endeavouring to incorporate muriatic acid gas with oil of turpentine, by putting this oil into the vessels in which the gas was received when extricated, found the oil change first yellow, then brown, and lastly, to be almost wholly coagulated into a crystalline mass, which comported itself in every respect like camphor. Tromsdorf and Boullay confirm this. A small quantity of camphor may be obtained from oil of turpentine by simple distillation at a very gentle heat. Other essential oils, however, afford more. By evaporation in shallow vessels, at a heat not exceeding 57° F., Proust obtained from oil of lavender .25, of sage .21, of marjoram .1014, of rosemary .0625. He conducted the operation on a pretty large scale.

Camphor is not soluble in water in any perceptible degrees, though it communicates its smell to that fluid, and may be burned as it floats on its surface. It is said, however, that a surgeon at Madrid has effected its solution in water by means of the carbonic acid.

Camphor may be powdered by moistening it with alkohol, and triturating it till dry. It may be formed into an emulsion by previous grinding with near three times its weight of almonds, and afterwards gradually adding the water. Yolk of egg and mucilages are also effectual for this purpose; but sugar does not answer well.

It has been observed by Romieu, that small pieces of camphor floating on water have a rotatory motion.

Alkohol, æthers, and oils, dissolve camphor.

The addition of water to the spirituous or acid solutions of camphor, instantly separates it.

Hatchett has particularly examined the action of sulphuric acid on camphor A hundred grains of camphor were digested in an ounce of concentrated sulphuric acid for two days. A gentle heat was then applied, and the digestion continued for two days longer. Six ounces of water were then added, and the whole distilled to dryness. Three grains of an essential oil, having a mixed odour of lavender and peppermint, came over with the water. The residuum being treated twice with two ounces of alkohol each time, fifty-three grains of a compact coal in small fragments remained undissolved. The alkohol, being evaporated in a water bath, yielded forty-nine grains of a blackish-brown substance, which was bitter, astringent, had the smell of caromel, and formed a dark brown solution with water. This solution threw down very dark brown precipitates, with sulphate of iron, acetate of lead, muriate of tin, and nitrate of lime. It precipitated gold in the metallic state. Isinglass threw down the whole of what was dissolved in a nearly black precipitate.

When nitric acid is distilled repeatedly in large quantities from camphor, it converts it into a peculiar acid." See *Camphoric acid.*

The use of this important medicine, in different diseases, is very considerable. It has been much employed, with great advantage, in fevers of all kinds, particularly in nervous fevers attended with delirium and much watchfulness. The experienced Werlhoff has witnessed its utility in several inflammatory diseases, and speaks highly in favour of its refrigerent qualities. The benefit derived from it in putrid fevers, where bark and acids are contra-indicated, is remarkable. In spasmodic and convulsive affections it is also of much service, and even in epilepsy. In chronic diseases this medicine is likewise employed; and against rheumatism, arthritis, and mania, we have several accounts of its efficacy. Nor is it less efficaceous when applied externally in certain diseases: it dissipates inflammatory tumours in a short time; and its antiseptic quality, in resisting and curing gangrene, is very considerable. Another property peculiar to this medicine, must not, however, be omitted; the power it possesses of obviating the strangury that is produced by cantharides, when sprinkled over a blister. The preparations of camphor are, *spiritus camphoræ, linimentum camphoræ, tinctura camphoræ composita*, and the *mistura camphoræ.* Camphor, dissolved in acetic acid with some essential oils, forms the aromatic vinegar.

Laurus cassia. *Cassia lignea; Canella malabarica; Cassia lignea Malabarica; Xylocassia; Canella malabarica et Javensis; Karva; Canella cubana; Arbor judaica; Cassia canella; Canellifera malabarica; Cinnamomum malabaricum; Calihacha canela.* Wild cinnamon-tree; Malabar cinnamon-tree, or cassia lignea-tree. Cassia lignea is the bark of the *Laurus* tree, the *foliis triplinerviis lanceolatis*, of Linnæus. The leaves are called *folia malabathri* in the shops. The bark and leaves abound with the flavour of cinnamon, for which they may be substituted; but in much larger doses, as they are considerably weaker.

Laurus cinnamomum. The systematic name of the cinnamon-tree. *Cinnamomum.* This tree affords the true cinnamon, which is its inner bark. Jacquin describes the tree thus: *Laurus cinnamomum; foliis trinerviis ovato-oblongis; nervis versus apicem evanescentibus.* Cinnamon bark is one of the most grateful of the aromatics; of a fragrant smell, and a moderately pungent, glowing, but not fiery taste, accompanied with considerable sweetness, and some degree of adstringency. It is one of the best cordial carminative and restorative spices we are in possession of, and is generally mixed with the diet of the sick. The essential oil, on account of its high price, is seldom used: a tincture, simple and spirituous water, are directed to be kept in the shops. The watery infusion of cinnamon is given with advantage to relieve nausea and check vomiting.

Laurus culilawan. The systematic name of the plant, the bark of which is called *cortex culilawan* in the shops. *Cullitlawan; Cortex caryophylloides. Laurus—foliis triplinerviis oppositis*, of Linnæus. This bark very much resembles cinnamon in appearance and properties.

Laurus nobilis. The systematic name of the sweet bay tree. *Laurus—foliis venosis lanceolatis perennantibus, floribus quadrifidis*, of Linnæus. This tree is a native of Italy, but cultivated in our gardens and shrubberies as a handsome evergreen. The leaves and berries possess the same medicinal qualities, both having a sweet fragrant smell, and an aromatic adstringent taste. The laurus of honorary memory, the distinguished favourite of Apollo, may be naturally supposed to have had no inconsiderable fame as a medicine; but its pharmaceutical uses are so limited in the practice of the present day, that this dignified plant is now rarely employed, except in the way of enema, or as an external application; thus the leaves are directed in the *decoctum pro fomento*, and the berries in the *emplastrum cumini.*

Laurus persea. This species affords the *Avigato pear*, which, when ripe, melts in the mouth like marrow, which it greatly resembles in flavour. It is supposed to be the most nutritious of all the tropical fruits, and grows in vast abundance in the West Indies and New Spain. The unripe fruit have but little taste; yet being very salubrious, are often eaten with salt and pepper. The sailors, when they arrive at the Havannah, and those parts, purchase them in great quantities; and chopping them into small pieces, with green capsicums, and a little salt, regale themselves heartily with them. They are esteemed also for their antidysenteric qualities, and are prepared in a variety of ways for the tables of the rich.

Laurus sassafras. The systematic name of the sassafras-tree. *Sassafras; Cornus mas odorata; Lignum pavanum; Anhuiba.* The wood of this tree, *Laurus—foliis trilobis integrisque*, of Linnæus, is imported from North America, in long straight pieces, very light, and of a spongy texture, and covered with a rough, fungous bark. It has a fragrant smell, and a sweetish, aromatic, subacrid taste; the root, wood, and bark, agree in their medicinal qualities, and are all mentioned in the pharmacopœias; but the bark is the most fragrant, and thought to be more efficacious than the woody part; and the branches are preferred to the large pieces. The medical character of this drug was formerly held in great estimation, and publications were professedly written on this subject. It is now, however, thought to be of little importance, and seldom used but in conjunction with other medicines, as a corrector of the fluids. It is an ingredient in the *decoctum sarsaparillæ compositum*, or *decoctum lignorum;* but the only officinal preparation of it is the essential oil, which is carminative and stimulant, and which may be given in the dose of two drops to ten.

LAVA. The cinders or product of volcanoes.

Lava'ndula. See *Lavendula.*

LAVENDER. See *Lavendula.*

Lavender, French. See *Lavendula stæchas.*

LAVE'NDULA. (From *lavo*, to wash: so called, because, on account of its fragrancy, it was used in baths.) 1. The name of a genus of plants in the Linnæan system. Class, *Didynamia;* Order, *Gymnospermia.* Lavender.

2. The pharmacopœial name of the common lavender. See *Lavendula spica.*

Lavendula spica. The systematic name of the common lavender. *Nardus italica. Lavendula—foliis sessilibus lanceolato-linearibus margine revolutis, spica interrupta nuda*, of

Linnæus. A native of the southern parts of Europe, but cultivated in our gardens on account of the fragrance of its flowers. Their taste is bitter, warm, and somewhat pungent; the leaves are weaker and less grateful. The essential oil, obtained by distillation, is of a bright yellow colour; of a very pungent taste, and possesses, if carefully distilled, the fragrance of the lavender in perfection. Lavender has been long recommended in nervous debilities, and various affections proceeding from a want of energy in the animal functions. The College directs an essential oil, a simple spirit, and a compound tincture, to be kept in the shops.

LAVENDULA STŒCHAS. The systematic name of the French lavender. *Stœchas; Stœchas arabica; Spica hortulana; Stucadore.* This plant is much less grateful in smell and flavour than the common lavender, to which it is allied in its properties.

LA'VER. (From *lavo*, to wash: so named because it is found in brooks, where it is constantly washed by the stream.)

1. The brook-lime.

2. The English name of a species of fucus which is eaten as a delicacy.

LAVIPE'DIUM. (From *lavo*, to wash, and *pes*, the foot.) A bath for the feet.

LAWSONIA. (After Mr. Lawson, a Scotchman, who published an excellent account of his voyage to Carolina, containing much information concerning the plants of that country.) The name of a genus of plants in the Linnæan system. Class, *Octandria;* Order, *Monogynia.*

LAWSONIA INERMIS. The systematic name of the true alkanna. *Alkanna vera; Alkanna orientalis.* An Oriental plant; the *Lawsonia —ramis inermibus*, of Linnæus; principally employed, in its native place, as a dye. The root is the officinal part; which, however, is rarely met with in the shops. It possesses adstringent properties, and may be used as a substitute for the *anchusa.*

LAXATI'VA. (From *laxo*, to loosen.) Gentle purgatives.

LAXA'TOR. (From *laxo*, to loosen: so called from its office to relax.) A name applied to muscles, the office of which is to relax parts into which they are inserted.

LAXATOR TYMPANI. *Externus mallei*, of Albinus; *Anterior mallei*, of Winslow; *Obliquus auris*, of Douglas; *Externus auris vel laxator internus*, of Cowper; and *Spheni salpingo mallien*, of Dumas. A muscle of the internal ear, that draws the malleus obliquely forwards towards its origin; consequently the membrana tympani is made less concave, or is relaxed.

LAXUS. Lax or diffused. Applied by botanists in opposition to *rectus* and *strictus;* as in the stem of the *Bunias cakile*, or sea rocket, the stem of which is described as *caulis laxus.*

LAZULITE. See *Azurite.*

LA'ZULUS. (From *azul*, Arabian.) A precious stone, of a blue colour. See *Lapis lazuli.*

LEAD. *Plumbum.* A metal found in considerable quantity in many parts of the earth, in different states, seldom, if at all, in the metallic state. It is found in that of oxide, *red lead ore*, mixed with a portion of iron, clay, and other earths. The colour of this ore is aurora red, resembling red arsenic. It is found in small lumps, of an indeterminate figure, and also crystallised in four-sided rhomboidal prisms.

Combined with carbonic acid, it forms the *sparry lead ore*, so called because it has the texture and crystallisation of certain spars. There are a great many varieties of this kind. It is found also united with sulphuric phosphoric, arsenic, molybdic, and chromic acids. Lastly, lead is found mineralised by sulphur, forming what is called *galena* (*sulphuret of lead*,) which is by far its most abundant ore. This ore, which is very common, is found both in masses and crystals. The primitive form of its crystals is a cube. Its colour is of a bluish lead grey. It has a considerable metallic lustre, its texture is foliated. It stains the fingers, and often feels greasy. It contains in general a minute quantity of silver.

Properties of Lead.—Lead is of a bluish white colour, and very brilliant when fresh cut. It is malleable. It soon tarnishes in the atmosphere. It may easily be cut with a knife, and stains the fingers bluish-grey when rubbed. It fuses at 612° Fahr. and renders other more refractory metals fusible. It becomes vitrified in a strong and continued heat, and vitrifies various other metals. It is the least elastic of all the metals. It is very laminable, but it possesses very little ductility. Its specific gravity is 11.435. It crystallises by cooling in small octahedra. When fused in contact with air, its surface first becomes yellow, and then red. It unites by fusion with phosphorus and sulphur. The greater part of the acids act upon it. The sulphuric acid requires the assistance of a boiling heat. Nitric acid is decomposed by it. Muriatic acid acts very weakly on it. Acetic acid dissolves it. Fluoric acid attacks it by heat, and slightly in the cold. It combines with other metals, but few of its alloys are applied to any use. When combined with mercury, it forms a crystallisable alloy which becomes fluid when triturated with that of bismuth.

Method of obtaining Lead.—In order to obtain lead in a great way, the ore is picked from among the extraneous matter with which it was naturally mixed. It is then pulverised and washed. It is next roasted in a reverberatory furnace, in which it is to be agitated, in order to bring the whole in contact with the air. When the external parts begin to soften, or assume the form of a paste, it is covered with charcoal, the mixture is stirred, and the heat increased gradually . the lead then runs on all sides, and is collected at the bottom of the furnace, which is perforated so as to permit the metal to flow into a receptacle defended by a lining of charcoal.

The scoriæ remaining above in the furnace still retain a considerable proportion of lead; in order to extract it, the scoriæ must be fused in a blast furnace. The lead is by that means separated, and cast into iron moulds, each of which contains a portion called *a pig of lead.* These pigs are sold under the name of *ore lead.*

In order to obtain perfectly pure lead, the lead of commerce may be dissolved in pure nitric acid, and the solution be decomposed by adding to it, gradually, a solution of sulphate of soda, so long as a precipitate ensues. This precipitate, which is sulphate of lead, must then be collected on a filter, washed repeatedly in distilled water, and then dried. In order to reduce it to its metallic state, let it be mixed with two or three times its weight of black flux, introduce the mixture into a crucible, and expose it briskly to a red heat.

"There are certainly two, perhaps three oxides of lead:—

1. The powder precipitated by potassa from the solution of the nitrate of lead, being dried, forms the yellow protoxide. When somewhat vitrified, it constitutes litharge, and combined with carbonic acid, white-lead or ceruse.

2. When massicot has been exposed for about 48 hours to the flame of a reverberatory furnace, it becomes red-lead, or minium.

3. If upon 100 parts of red-lead we digest nitric acid of the sp. gr. 1.26, 92.5 parts will be dissolved, but 7.5 of a dark brown powder will remain insoluble. This is the peroxide of lead.

Chloride of lead is formed, either by placing lead in chlorine, or by exposing the muriate to a moderate heat. It is a semi-transparent greyish-white mass, somewhat like horn, whence the old name of *plumbum corneum*.

The iodide is easily formed, by heating the two constituents. It has a fine yellow colour. It precipitates when we pour hydriodate of potassa into a solution of nitrate of lead.

The salts of lead have the protoxide for their base, and are distinguishable by the following general characters :—

1. The salts which dissolve in water, usually give colourless solutions, which have an astringent sweetish taste.
2. Placed on charcoal they all yield, by the blowpipe, a button of lead.
3. Ferroprussiate of potassa occasions in their solutions a white precipitate.
4. Hydrosulphuret of potassa, a black precipitate.
5. Sulphuretted hydrogen, a black precipitate.
6. Gallic acid, and infusion of galls, a white precipitate.
7. A plate of zinc, a white precipitate, or metallic lead.

Most of the acids attack lead. The sulphuric does not act upon it, unless it be concentrated and boiling. Sulphurous acid gas escapes during this process, and the acid is decomposed. When the distillation is carried on to dryness, a saline white mass remains, a small portion of which is soluble in water, and is the sulphate of lead; it affords crystals. The residue of the white mass is an insoluble sulphate of lead.

Nitric acid acts strongly on lead.

The nitrate solution, by evaporation, yields tetrahedral crystals, which are white, opaque, and possess considerable lustre.

A *subnitrate* may be formed in pearl-coloured scales, by boiling in water equal weights of the nitrate and protoxide.

Muriatic acid acts directly on lead by heat, oxidising it, and dissolving part of its oxide.

The acetic acid dissolves lead and its oxides; though probably the access of air may be necessary to the solution of the metal itself in this acid. *White-lead*, or *ceruse*, is made by rolling leaden plates spirally up, so as to leave the space of about an inch between each coil, and placing them vertically in earthen pots, at the bottom of which is some good vinegar. The pots are to be covered, and exposed for a length of time to a gentle heat in a sand bath, or by bedding them in dung. The vapour of the vinegar, assisted by the tendency of the lead to combine with the oxygen which is present, corrodes the lead, and converts the external portion into a white substance which comes off in flakes, when the lead is uncoiled. The plates are thus treated repeatedly, until they are corroded through. Ceruse is the only white used in oil paintings. Commonly it is adulterated with a mixture of chalk in the shops. It may be dissolved without difficulty in the acetic acid, and affords a crystallisable salt, called *sugar of lead*, from its sweet taste. This, like all the preparations of lead, is a deadly poison. The common sugar of lead is an acetate; and Goulard's extract, made by boiling litharge in vinegar, a subacetate. The power of this salt, as a coagulator of mucus, is superior to the other. If a bit of zinc be suspended by brass or iron wire, or a thread, in a mixture of water and the acetate of lead, the lead will be revived, and form an arbor Saturni.

The acetate, or sugar of lead, is usually crystallised in needles, which have a silky appearance.

The subacetate crystallises in plates. The sulphuret, sulphate, carbonate, phosphate, arseniate, and chromate of lead, are found native.

When lead is alloyed with an equal weight of tin, or perhaps even less, it ceases to be acted on by vinegar. Acetate and subacetate of lead in solution, has been used as external applications to inflamed surfaces, and scrofulous sores, and as eye-washes. In some extreme cases of hæmorrhagy from the lungs and bowels, and uterus, the former salt has been prescribed, but rarely and in minute doses, as a corrugant or astringent. The colic of the painters, and that formerly prevalent in certain counties of England, from the lead used in the cyder presses, show the very deleterious operation of the oxide, or salts of this metal, when habitually introduced into the system in the minutest quantities at a time. Contraction of the thumbs, paralysis of the hand, or even of the extremities, have not unfrequently supervened. A course of sulphuretted hydrogen waters, laxatives, of which sulphur, castor oil, sulphate of magnesia, or calomel, should be preferred, a mercurial course, the hot sea-bath, and electricity, are the appropriate remedies.

Dealers in wines have occasionally sweetened them, when acescent, with litharge or its salts. This deleterious adulteration may be detected by sulphuretted hydrogen water, which will throw down the lead in the state of a dark brown sulphuret. Or, subcarbonate of ammonia, which is a very delicate test, may be employed to precipitate the lead in the state of a white carbonate; which, on being washed and digested with sulphuretted hydrogen water, will instantly become black. If the white precipitate be gently heated, it will become yellow, and, on charcoal before the blowpipe, it will yield a globule of lead. Chromate of potassa will throw down from saturnine solutions a beautiful orange-yellow powder. Burgundy wine, and all such as contain tartar, will not hold lead in solution, in consequence of the insolubility of the tartrate.

The proper counter-poison for a dangerous dose of sugar of lead, is a solution of Epsom or Glauber salt, liberally swallowed; either of which medicines instantly converts the poisonous acetate of lead into the inert and innoxious sulphate. The sulphuret of potassa, so much extolled by Navier, instead of being an antidote, acts itself as a poison on the stomach.

Oils dissolve the oxide of lead, and become thick and consistent; in which state they are used as the basis of plasters, cements for water-works, paints, &c.

Sulphur readily dissolves lead in the dry way, and produces a brittle compound, of a deep grey colour and brilliant appearance, which is much less fusible than lead itself; a property which is common to all the combinations of sulphur with the more fusible metals.

The phosphoric acid, exposed to heat together with charcoal and lead, becomes converted into phosphorus, which combines with the metal. This combination does not greatly differ from ordinary lead: it is malleable, and easily cut with a knife; but it loses its brilliancy more speedily than pure lead; and when fused upon charcoal with the blowpipe, the phosphorus burns, and leaves the lead behind.

Litharge fused with common salt decomposes it; the lead unites with the muriatic acid, and forms a yellow compound, used as a pigment. The same decomposition takes place in the humid way, if common salt be macerated with litharge; and the solution will contain caustic alkali.

Lead unites with most of the metals. Gold and silver are dissolved by it in a slight red heat. Both these metals are said to be rendered brittle by a small admixture of lead, though lead itself is rendered more ductile by a small quantity of them. Platina forms a brittle compound with lead; mercury amalgamates with it; but the lead is separated from the mercury by agitation, in the form of an impalpable black powder, oxygen being at the same time absorbed. Copper and lead do not unite but with a strong heat. If lead be heated so as to boil and smoke, it soon dissolves pieces of copper thrown into it; the mixture, when cold, is brittle. The union of these two metals is remarkably slight; for, upon exposing the mass to a heat no greater than that in which lead melts, the lead almost entirely runs off by itself. This process is called eliquation. The coarser sorts of lead, which owe their brittleness and granulated texture to an admixture of copper, throw it up to the surface on being melted by a small heat. Iron does not unite with lead, as long as both substances retain their metallic form. Tin unites very easily with this metal, and forms a compound, which is much more fusible than lead by itself, and is, for this reason, used as a solder for lead. Two parts of lead and one of tin, form an alloy more fusible than either metal alone: this is the solder of the plumbers. Bismuth combines readily with lead, and affords a metal of a fine close grain, but very brittle. A mixture of eight parts bismuth, five lead, and three tin, will melt in a heat which is not sufficient to cause water to boil. Antimony forms a brittle alloy with lead. Nickel, cobalt, manganese, and zinc, do not unite with lead by fusion."

The preparations of lead used in medicine are:—

1. Plumbi subcarbonas. See *Plumbi subcarbonas.*

2. Oxidum plumbi rubrum. See *Minium.*

3. Oxidum plumbi semivitreum. See *Lithargyrus.*

4. Acetas plumbi. See *Plumbi acetas.*

5. Liquor plumbi acetatis. See *Plumbi acetatis liquor.*

6. Liquor plumbi acetatis dilutus. See *Plumbi acetatis liquor dilutus.*

Lead, white. See *Plumbi subcarbonas.*

LEAF. *Folium.* A laminar expansion of a plant generally of a green colour.

It is difficult, however, to define this universal and important organ of vegetables.

They are considered as the respiratory organs of plants.

Leaves are, for the most part, remarkable for their expanded form; their colour is almost universally green, their internal substance pulpy and vascular, sometimes very succulent, and their upper and under surfaces differ commonly in hue, as well in kind or degree of roughness.

In discriminating the species of plants, a knowledge of the various forms of leaves is of the utmost importance. Botanists, therefore, have paid particular attention to their names, which are derived either from their origin, distribution, situation, direction, insertion, form, base, point, margin, surface, distribution of its vessels, nerves, expansion, substance, duration, composition, &c.

A leaf consists of a thin and expanded part, which in common language is named the leaf, and a stalk called the *petiole* or *petiolus.* The surface of a leaf, *superficies,* or *pagina,* is distinguished into the upper part, or face, and the under part, or back of the leaf. The *base,* or *origin* of a leaf, is that part next the stem or branch; the *apex* is the termination of the leaf; the *margin* or edge, the circumference; the disk, *discum,* is the middle part of the surfaces within the margin.

From their *origin,* we have the following terms:

1. *Seminal; folia seminalia,* which are the first leaves of the majority of plants, proceeding from seeds that have more than one seed-lobe; they are seen in Raphanus sativus, and Cannabis sativa.

2. *Radical,* which spring directly from the root: as in Leontodon taraxacum, and Viola odorata.

3. *Cauline,* or stem-leaf. The *Valeriana phu* has its radical leaves undivided, and the cauline leaves pinnate.

4. *Ramial,* or branch-leaf, which are only described when they differ from those of the stem. The *Sison ammi* has its radical leaves, linear; its cauline, setous; and its branch leaves, tripinnate.

5. *Axillary,* when seated on joints or axillæ; as in Parthenium integrifolium.

6. *Floral,* when next the flower, and like the other leaves; as in Lonicera caprifolium.

From their *distribution* on the stem and branches, leaves are named,

7. *Alternate,* when not in pairs, and are given off in various directions, one after another; as in Malva rotundifolia.

8. *Opposite,* when they appear directly on opposite sides of the stem, in pairs; as in Lamium album, and Urtica dioica.

9. *Two-ranked; folia disticha,* which implies that they spread in two directions, and yet are not regularly opposite at their insertion; as in Cupressus disticha, Taxus baccata, Pinus picea, and Lonicera symphori-carpos.

10. *Bifarial,* that is, two-ranked, but given off from the side only of the branch; as in Carpinus betulus, and Fagus sylvatica.

11. *Unilateral,* looking to one side only; as in Convallaria multiflora.

12. *Scattered,* irregular or without any order; as in Reseda luteola, and Sedum reflexum.

13. *Decussate,* crossing each other in pairs, cross-like; as in Euphorbia lathyris, and Crassula tetragona.

14. *Imbricate,* like tiles upon a house; as in Cupressus sempervirens, and Aloe spiralis.

15. *Fasciculate,* or tufted, when several spring from the same point; as in Pinus larix, and Berberis vulgaris.

16. *Stellate,* star-leaved, whirled; several leaves growing in a circle round the stem, without any reference to the precise number; as in Rubia tinctorum, Lilium martagon, Asperula odorata. In large natural genera it is necessary to mention the number; as in Galium.

17. *Remote,* when at an unusual distance from each other.

18. *Clustered;* crowded together; as in Antirrhinum linaria, and Trientalis europea.

19. *Binal,* when there is only two on a plant; as in Galanthus nivalis, Scilla bifolia, and Convallaria magalis.

20. *Ternal*, three together; as in Verbena triphylla.

21. *Quaternal Quinal*, &c., when four, five, or more are situated together; as in various species of Erica.

From their determinate *direction*, leaves are distinguished into,

22. *Close-pressed; adpressa;* when their upper surface is close to the stem; as in Thlaspi campestris, and Xeranthemum sesamoides.

23. *Erect*, when nearly perpendicular, or forming a very acute angle with the stem; as in Juncus articulatus, and Bryum unquiculatum.

24. *Spreading*, forming a moderately acute angle with the stem; as in Atriplex portulacoides, Nerium oleander, and Veronica beccabunga.

25. *Horizontal*, spreading in the greatest possible degree; as in Gentiana campestris, and Pelargonium patulum.

26. *Ascending*, rising gently, so as to be somewhat arched; as in Geranium nitifolium.

27. *Recurved*, reflexed, curved backward; as in Erica retorta, and Bryum pellucidum.

28. *Reclined*, depending, hanging downward towards the earth; as in Cichorium intybus, and Leonurus cardiaca.

29. *Oblique*, twisted, so that one part is vertical, the other horizontal; as Allium obliquum, and Fritallaria obliqua.

30. *Adverse*, the upper surface turned to the meridian, not the sky; as in Lactuca scariola.

31. *Resupinate*, or reversed, when the upper surface is turned downward; as in Alstromeria pelegrina, and Stœbe prostrata.

32. *Revolute*, having a spiral apex; as Dianthus carthusianorum, and barbatus.

33. *Rooting*, sending rootlets into the earth; as Asplenium rhizophylla.

34. *Floating* on the surface of the water; as in Potamogeton natans, and Nymphæa alba.

35. *Submersed*, demersed, immersed, under water; as Hottonia palustris, and Ranunculus aquatilis.

From their *insertion* into,

36. *Petiolate*, leaves on footstalks; as Prunus cerasus, and Verbascum nigrum.

37. *Sessile*, without footstalk, lying immediately on the stem; as in Saponaria officinalis, and Pinguicula vulgaris.

38. *Adnate*, the upper surface adhering a little way to the branch; as in Xeranthemum vestitum.

39. *Decurrent*, when a lamellar part of the leaf runs down the stem, or branch: as in Carduus spinosus, and Verbascum thapsus.

40. *Connate*, when two opposite leaves embrace, and are united at their bases; as in Cerastium perfoliatum, and Dipsacus laciniatus.

41. *Connato-perfoliate*, when the union is in the whole or nearly the whole breadth of the leaves, so as to give the two leaves the appearance of being united into but one leaf; as in Eupatorium perfoliatum, and Lonicera dioica. Connate leaves are, in some instances, united by a membrane, which stretching from the margins of the opposed leaves, near the base, forms a kind of pitcher around the stem, in which the rain is retained; as in Dipsacus fullonium.

42. *Embracing*, clasping the stem with their bases: as in Carduus marianus, and Papaver somniferum.

43. *Vaginate*, sheathing the stem at their bases, as in Canna indica, and Polygonum bistorta.

44. *Peltate*, when the footstalk is inserted not into the basis, but into the disk of the leaf, as in Drosera peltata, and Tropæolum majus.

45. *Perfoliate*, when the stem runs through the leaf; as in Bupleurum rotundifolium, and Uvularia perfoliata.

46. *Articulate*, one leaf growing out of the apex of another; as Cactus opuntia, and Cactus ficus indica.

From the *basis* of the leaf, it is called,

47. *Cordate*, heart-shaped, or ovate, hollowed out at the base; as Arctium lappa, and Tamus communis.

48. *Arrow-shaped*, triangular, hollowed out very much at the base; as Rumex acetosa, and Sagittaria sagittifolia.

49. *Hastate*, halberd-shaped, triangular, hollowed out at the base and sides, but with spreading lobes; as in Arum maculatum, and Rumex acetosella.

50. *Reniform*, kidney-shaped, a short, broad, roundish leaf, the base of which is hollowed out; as Asarum Europeum, and Glecoma hederacia.

51. *Auricled*, furnished at its base with a pair of leaflets, properly distinct, but occasionally joined with it; as in Citrus aurantium.

Linnæus uses the term *appendiculatum*, which is correct.

52. *Unequal*, the basis larger on one side than the other; as in Tilia Europea, and Piper tuberculatum.

The form of the *apex* of a leaf, gives rise to the following names:

53. *Acute*, sharp, ending in an acute angle, which is common to a great number of plants: example in Linum angustifolium, and Campanula trachelium.

54. *Acuminate*, pointed, having a taper, or awl-shaped point; as Arundo phragmitis, and Syringa vulgaris.

55. *Cuspidate*, or *mucronate*, sharp pointed, tipped with a rigid spine, as in the thistles, and Ficus religiosa.

56. *Obtuse*, blunt, terminating in a segment of a circle; as Rumex obtusifolius, and Hypericum quadrangulum.

57. *Retuse*, ending in a broad shallow notch; as in Ervum ervilia, and Rumex digynus.

58. *Præmorse*, jagged pointed, as if bitten off; very blunt, with various irregular notches; as in Hibiscus præmorsus, and Swartz's genus Aëride.

59. *Truncate*, an abrupt leaf, with the extremity cut off, as it were, by a transverse line; as in Liriodendron tulipifera.

60. *Dedaleous*, with a broad, incised, and crisp apex; as in Asplenium scolopendrum.

61. *Emarginate*, nicked, having a small notch at the summit; as Hydrocotile vulgaris, and Euphorbia tuberosa.

62. *Summit-cut,—folia apice incisa;* as in Glinko biloba.

63. *Cirrhose*, tipped with a tendril; as in Lathyrus articulatus, and Gloriosa superba.

64. *Tridentate*, three-toothed; an obtuse point, beset with three teeth; as in Buchera Æthiopica, and Genista tridentata.

65. *Ascidiate*, or pitcher-leaf, a cylindrical tube, filled with water; as in Nepenthes distillatoria, and Saracenia.

The names derived from the *margin* of the leaf, are,

66. *Entire*, not divided; as in Tragopogon pratense, and porrifolium.

67. *Very entire, integerrima*, the margin void of irregularity; as Citrus aurantium.

68. *Undulate*, when the disk near the margin is waved obtusely up and down; as in Panicum hirtellum, and Reseda lutea.

69. *Crenate*, notched, when the teeth are rounded, and not directed towards either end of

the leaf; as in Betonica officinalis, and Scutellaria galericulata.

70. *Doubly crenate*, the greater teeth, notched with smallar ones; as in Salvia sclara, and Ranunculus auricomus.

71. *Serrate*, when the teeth are sharp, and resemble those of a saw, pointing towards the extremity of the leaf; as in Sedum telephium.

72. *Acutely serrate;* as in Thymus acinos.

73. *Obtusely serrate;* as in Ballota nigra.

74. *Doubly serrate*, having a series of smaller serratures intermixed with the larger: as in Rubus fruticosus, and Campanula trachelium.

75. *Dentate*, toothed, beset with projecting, horizontal, rather distant teeth of its own substance; as the lower leaves of the Centaurea cyanus, and Campanula trachelium.

76. *Jagged*, irregularly cut or notched, especially when otherwise also divided; as in Salvia æthiopia, and Senecio squalidus.

77. *Cartilaginous-edged*, hard, and hoary; as in Saxifraga callosa, and Yucca gloriosa.

78. *Prickle-edged*, beset with prickles; as in Carduus lanceolatus, and Ilex aquifolium.

79. *Fringed*, bordered with soft parallel hairs; as in Sempervivum tectorum, and Galium cruciatum.

From the *openings*, or *sinuses*, in the margin,

80. *Sinuated*, cut as it were into rounded, or wide openings; as in Quercus robur, and Alcea rosea.

81. *Repand*, wavy, bordered with numerous angles and segments of circles, alternately; as in Menyanthes nymphoides, and Erysimum alliaria.

82. *Pinnatifid*, cut transversely into several oblong parallel segments; as in Centaurea calcitrapa, and Scabiosa arvensis.

83. *Bipinnatifid*, doubly pinnatifid; as in Papaver argemone.

84. *Lyrate*, lyre-shaped, cut into several transverse segments, gradually larger towards the extremity of the leaf, which is rounded; as in Geum urbanum, and Erysimum barbarea.

85. *Panduriform*, fiddle-shaped, oblong, broad at the two extremities, and contracted in the middle; as in Rumex pulcher, and Convolvulus panduratus.

86. *Runcinate*, lion-toothed, cut into several transverse, acute, segments, pointing backwards; as in Leontodon taraxacum, and Erysimum officinale.

87. *Laciniate*, cut into numerous irregular portions; as in Ranunculus parviflorus, and Geranium columbinum, and Cotyledon laciniata.

88. *Squarrose*, the margin beset with a rough fringe; as in Centaurea calcitrapa, and Carduus marianus.

89. *Partite*, deeply divided nearly to the basis; as in Helleborus viridis; *bipartite*, *tripartite*, and *multipartite*, according to the number of the divisions.

90. *Trifid*, divided into three; as in Bidens tripartita.

91. *Quinquifid*, divided into five; as in Geranium maculatum.

92. *Multifid*, the margin of round leaves cut from the apex almost to the base, without leaving any great intermediate sinuses; as in Aconitum napellus, and Cucumis colocynthis.

From the *angles* in the margin of the leaf,

93. *Rounded*, the margin not having any angle.

94. *Angulate*, the margin having acute angles.

a. *Triangular;* as in Chenopodium bonus henricus, and Atriplex hortensis.

b. *Quinqueangular;* as in Geranium peltatum.

c. *Septangular;* as in Hibiscus abelmoschus.

95. *Rhomboid*, *trapeziform*, or approaching to a square; as in Chenopodium vulvaria, and Trapa natans.

96. *Quadrangular*, with four angles; as in Liriodendron tulipifera.

97. *Deltoid*, trowel-shaped, having three angles, of which the terminal one is much further from the base, than the lateral ones; as in Mesembryanthemum deltoideum, and Populus nigra.

98. *Lobate*, when the margins of deep segments are rounded, hence:

a. *Two-lobed;* as in Bauhinia porresta.

b. *Three-lobed;* as in Anemone hepatica.

c. *Five-lobed;* as in Humulus lupulus, and Acer pseudo-platanus.

99. *Palmate*, cut into several oblong, nearly equal segments, about half way, or rather more, towards the base, leaving an entire space, like the palm of the hand; as in Passiflora cœrulea, and Alcea ficifolia.

From the *figure of the circumstance*, are derived the following names:

100. *Orbiculate*, circular, the length and breadth of which are equal, and the circumference in an even circular line; as in Cotyledon orbiculata, and Hydrocotile vulgaris.

101. *Subrotund*, roundish; as in Pyrola, and Malva rotundifolia.

102. *Oblong*, three or four times longer than broad; as in Musa sapientum, and Elæagnus orientalis.

103. *Ovate*, of the shape of an egg, cut lengthwise, the base being rounded, and broader than the extremity; as in Origanum vulgare, and Inula helenium.

104. *Obovate*, of the same figure, with the broader end uppermost; as in Primula veris, and Samulus valerandi.

104.* *Oval*, ovate, but each end has the same roundness; as in Rhus catinus, and Mammea americana.

105. *Elliptical*, oval, the longitudinal diameter being greater than the transverse.

106. *Parabolic*, oblong, the summit narrow and round; as in Marrubium pseudodictamnus.

107. *Cuneiform*, wedge-shaped, broad and abrupt at the summit, and tapering down to the base; as Saxifraga cuneifolia, and Iberis semperflorens.

108. *Spatulate*, of a roundish figure, tapering to an oblong base; as in Cotyledon spuria, and Cucubalus otites.

109. *Lanceolate*, of a narrow oblong form, tapering towards each end; as in Plantago lanceolata.

110. *Linear*, narrow, with parallel sides; as in Senecio linifolius.

111. *Capillary*, long, fine, and flexible, resembling a hair; as in Anethum fœniculum, and Graveolens.

112. *Setaceous*, bristly; as in Asparagus officinalis, and Scirpus setaceus.

113. *Acerose*, needle-shaped, linear and evergreen, generally acute and rigid; as in Pinus sylvestris, and Juniperus communis.

From the difference of the *surface* of leaves:

114. *Glabrous*, smooth, without roughness; as the leaves of most plants.

115. *Nitid*, smooth and shining; as in Laurus nobilis, and Canna indica.

116. *Lucid*, as if covered with a varnish; as in Angelica lucida, and Royena lucida.

117. *Viscid*, covered with a clammy juice; as in Senecio viscosus, and Erygeron viscosum.

118. *Naked*, without bristles, or hairs; as the leaves of many plants.

119. *Scabrous*, or *asperous*, with little rough-

ness visible, as well as tangible; as in Morus nigra, and Humulus lupulus.

120. *Punctate*, dotted, perforated with little holes; as in Hypericum perforatum.

121. *Pertuse*, bored, naturally having large perforations; as in Dracontium pertusum.

122. *Maculate*, spotted; as in Orchis maculata, and Pulmonaria officinalis.

123. *Coloured*, being of any other than a green colour; as in Amaranthus tricolor, and Atriplex hortensis rubra.

124. *Hoary*, having a whitish mealy surface; as in Populus alba.

125. *Lineate*, having superficial lines; as in Scirpus maritimus.

126. *Striate*, marked with coloured lines; as in Phalaris arundinacea.

127. *Sulcate*, furrowed, having broad and deep furrows; as in Digitalis ferruginea.

128. *Rugose*, rugged; as in Salvia sclara.

129. *Bullate*, blistered, a greater degree of the last; as in Brassica oleracea.

130. *Papulous*, or *vesiculous*, covered with hollow vesicles; as in Mesembryanthemum crystallinum.

131. *Papillose*, or *Varicose*, covered with solid wart-like tubercles; as in Aloe margaritifera.

132. *Glandular*, covered with small glandiform bodies; as in Salix alba, and Prunus padus.

From the *distribution of the vessels on the surface* of the leaf,

Nerves are white elevated chords, which originate from the base of the leaf.

A *rib* is the middle nerve, thick, and extending from the basis to the apex of the leaf.

Veins are anastomosing vessels which are given off from the costa or rib.

The greater clusters of vessels are generally called *nervi* or *costæ*, nerves or ribs, and the smaller *venæ*, whether they are branched or reticulate, simple or otherwise.

133. A *nervous* or *ribbed* leaf is where they extend in simple lines from the base to the point; as in the *Convallariæ*, and *Helianthus annuus*. The Laurus camphora is an example of a trinerve; the Smilax tetragona has five nerves; the Dioscorea septemloba, seven.

134. When a pair of large ribs branch off from the main one above the base, and run in a straight line towards the apex, as in Helianthus tuberosus, the leaf is said to be *triple nerved*.

135. When two go from the base and four from the costa in a straight line, it is termed *folium quintuplinervum*.

136. *Venous*, veiny, when the vessels by which the leaf is nourished are branched, subdivided, and more or less prominent, forming a net-work over either, or both its surfaces; as in Clusia venosa, and Verbascum lychritis.

137. *Avenial*, or veinless, when without veins; as in Clusia alba, and rosea.

138. *Enervous*, ribless, when no nerve is given off from the base; as in Asperula levigata.

The terms from the *expansion* of the leaves are,

139. *Flat*, as most leaves are,

140. *Concave*, hollow, depressed in the middle; as in Saxifraga stolonifera.

141. *Convex*, the reverse of the former; as in Ocymum basilicum majus.

142. *Canaliculate*, channelled, having a longitudinal furrow; as in Plantago maritima.

143. *Cucullate*, hooded, when the edges meet in the lower parts, and expand in the upper; as in Geranium cucullatum, and that curious genus Saracenia.

144. *Plicate*, plaited, when the disk of the leaf, especially towards the margin, is acutely folded up and down; as in the Malvas, and Alchemilla vulgaris.

145. *Undulate*, waved, when the disk near the margin is waved obtusely up and down; as in Reseda lutea, and Ixia undulata.

146. *Crisp*, curled, when the border of the leaf becomes more expanded than the disk, so as to grow elegantly, curled, and twisted; as in Malva crispa.

From the *internal substance*:

147. *Membranaceous*, when there is scarcely any pulp between the external membranes of the leaf; as in Citrus aurantium, and the leaves of many plants.

148. *Thick*, the membranes being rather more than usually firm; as in Sedum telephium.

149. *Carneous*, fleshy, of a thick substance, as in all those called succulent plants; as Crassula lactea, and Sempervivum tectorum.

150. *Pulpy*, very thick, and of the consistence of a plumb; as in Mesembryanthemum verruculatum.

151. *Tubular*, hollow within; as in Allium cepa. The leaf of the Lobelia dortmanna is very peculiar, in consisting of a double tube.

152. *Compact*, not hollow.

153. *Rigid*, easily broken on being bent; as in Stapelia.

The thick leaves, *folia crassa*, afford the following distinctions:

154. *Gibbous*, swelling on one side, or both, from excessive abundance of pulp; as in Crassula cotyledon, and Aloe retusa.

155. *Round*, cylindrical; as in Allium schœnoprasum, and Salsola sativa.

156. *Subulate*, awl-shaped, tapering from a thickish base to a point; as in Allium ascalonicum, and Narcissus jonquilla.

157. *Compressed*, flattened laterally; as in Cacalia ficoides.

158. *Depressed*, flattened vertically; as in Crassula tetragona.

159. *Triquetral*, thick, and triangular; as in Butomus umbellatus.

160. *Tetragonal*, quadrangular and awl-shaped; as in Gladiolus tristis.

161. *Lingulate*, tongue-shaped, a thick oblong, blunt figure, and a little convex on its inferior surface; as in Mesembryanthemum linguiforme.

162. *Ancipital*, two-edged; as in Typha latifolia.

163. *Ensiform*, sword-shaped, two edges tapering to a point, slightly convex on both surfaces, neither of which can properly be called upper or under; as in Iris germanica, and Gladiolus communis.

164. *Carinate*, keeled, when the bark is longitudinally prominent; as in Allium carinatum, and Narcissus biflorus.

165. *Acinaciform*, cimeter-shaped, compressed with one thick and straight edge, the other thin and curved; as in Mesembryanthemum acinaciforme.

166. *Dolabriform*, hatchet-shaped, compressed with a very prominent dilated keel, and a cylindrical base; as in Mesembryanthemum dolabriforme.

167. *Uncinate*, hooked, flat above, compressed at its sides, and turned back at the apex, forming a hook.

When the shape of membranaceous leaves is imperfect, the particle *sub* is attached, as *sub*-sessile, *sub*-ovate, *sub*-pilous, &c.

When the shape is *reversed*, by the prefixing the preposition *ob*, as *ob*-cordate, when the point is inserted into the petiole, *ob*-ovate, &c.

From the *coadunation*, leaves are designated by prefixing the prominent shape, as *lanceolato-ovate*, as in Nicotiana tabacum: and ovato-lanceolate, lanceolate, but swelling out in the middle; as in Saponaria officinalis.

From their *duration*, leaves are termed,

168. *Deciduous*, falling off at the approach of winter, as in most European trees and shrubs.

169. *Caducous*, falling off in the middle of summer.

170. *Perennial*, green the whole year, and falling off as the new ones appear.

171. *Persistant*, lasting many years, and always green; as in Pinus and Taxus.

All the foregoing terms belong to *simple leaves*, or those which have one leaf only on the petiole or footstalk.

The following regard *compound leaves*, or such as consist of two or any greater number of *foliola*, or leaflets, connected by a common footstalk.

172. *Digitate*, fingered, when several leaflets proceed from the summit of a common footstalk; as in Trifolium pratense.

173. *Pinnate*, when several leaflets proceed laterally from one footstalk, instead of being supported at the top; as in Acacia pseudacacia.

A digitate leaf is called after its *mode of digitation*,

174. *Conjugate*, or yoked, when there is one pair of leaflets, or *pinnæ;* as in Zygophillum fabago.

175. *Binate*, when the pair of leaflets unite somewhat at their base; as in Lathyrus sylvestris.

176. *Ternate*, where there are three leaflets; as in Trifolium pratensis, and Oxalis acetosella.

177. *Quinate*, there being five leaflets; as in Potentilla reptans, and Lupinus albus.

178. *Septenate*, with seven; as in Æsculus hippocastanum.

179. *Novenate*, nine; as in Sterculia fœtida.

180. *Pedate*, a peculiar kind of leaf, being ternate, with its lateral leaflets compounded in their fore-part; or a leaf with a bifid footstalk divided into two diverging branches, with an intermediate leaflet, and each supporting two or more lateral leaflets on their anterior edge; as in Helleborus niger.

181. *Articulate*, jointed, when one, or a pair of leaflets, grows out of the summit of another, with a sort of joint; as in Cactus ficus indica, and Fagara tragodes.

Pinnate leaves are called from their number of *pinnæ*,

182. *Bipinnate*, or *duplicato-pinnate*, doubly pinnate; as in Tanacetum vulgare.

183. *Tripinnate*, or *triplicato-pinnate*, three pinnate; as in Scandix odorata.

From the *number of pairs*, pinnate leaves are termed,

184. *Biguga;* as in Mimosa nodosa.

185. *Triguga;* as in Cassia emarginata.

186. *Quadriguga;* as in Cassia longisiliqua.

187. *Quinquiguga;* as in Cassia occidentalis.

188. *Multiguga;* as in Cassia javanica.

The difference in the *termination* of a pinnate leaf,

189. *Impari-pinnate*, with an odd or terminal leaflet; as Rosa centifolia.

190. *Abrupti-pinnate*, with a terminal leaflet; as in Orobus tuberosus.

191. *Cirrhosi-pinnate*, when furnished with a tendril in place of an odd leaflet; as in the pea and vetch tribe.

From the mode of *adhesion of the leaflets* arise,

192. *Oppositely-pinnate*, when the leaflets are opposite, or in pairs; as in Sium angustifolium.

193. *Alternately-pinnate*, when alternate; as in Vicia sativa.

194. *Interruptedly-pinnate*, when the principal leaflets are arranged alternately with an intermediate series of smaller ones; as in Spiræa ulmaria.

195. *Decurrently-pinnate*, when the leaflets are decurrent; as in Eryngium campestre.

196. *Jointedly-pinnate*, with apparent joints in the common footstalk; as in Fagara tragodes.

197. *Petiolato-pinnate*, the leaflets on footstalks; as in Robinia pseudacacia.

198. *Alate-pinnate*, when the footstalk has little wings between the leaflets.

199. *Sessile-pinnate*, with leaflets within any petiole.

200. *Conjugate-pinnate*, confluent; the leaflets growing somewhat together at their margins.

From their *bipinnation*, pinnate leaves are,

201. *Bigeminate*, two-paired: as in Mimosa unguis cate.

202. *Trigeminate*, or *triplicato-geminate*, thrice paired; as in Mimosa tergemina.

From the *tripinnation*,

203. *Doubly-ternate*, or *duplicato-ternate*, when the common footstalk supports these secondary petioles on its apex, and each of these support three leaflets; as in Epimedium alpinum.

204. *Triternate*, or *triplicato-ternate*, when the common petiole supports on its apex three secondary footstalks, each of which supports three ternary ones, and every one of these three leaflets; as in Aquilegia vulgaris, and Fumaria enneaphylla.

205. *Multiplicato-pinnate*, there being more than three orders; as in Ruta hortensis.

Pinnæ, are the leaflets of pinnate leaves.

206. *Pinullæ*, the leaflets of the double and triple range of pinnate leaves.

LEÆ'NA. (From λεαινα, a lioness.)

1. The lioness.

2. The name of a plaster, so called from its great power.

LEAKE, John, was born in Cumberland, and after qualifying himself as a surgeon in London, travelled to Portugal and Italy. On his return he settled in the metropolis, and published a dissertation on the Lisbon Diet Drink. He not long after became a licentiate of the college of physicians, and began to lecture on Midwifery. In 1765, he originated the plan for the Westminster Lying-in Hospital, and purchased a piece of ground for the purpose. His death occurred in 1792. He published a volume of "Practical Observations on Child-bed Fever;" "Medical Instructions," concerning the Diseases of Women; in two volumes, which passed through several editions; and some other works.

LE CLERC, Daniel, was born at Geneva, in 1652. His father being professor in the Greek language, instructed him in the rudiments of knowledge, and gave him a taste for researches into antiquity. He afterwards studied at different universities, and took his medical degree at Valence at the age of 20. Returning to his native city, he soon got into considerable practice; which he at length relinquished in 1704, on being appointed a member of the council of state, and that he might complete his various literary undertakings, which had already greatly distinguished him. His death occurred in 1728. He had published in conjunction, with Mangets, "Bibliotheca Anatomica," in two volumes, 1685. But his most celebrated work is the "Histoire de la Médecine," from the earliest times to that of Galen, which evinces immense erudition. He afterwards added a plan for continuing it to the middle of the 17th century. But Dr. Friend has completed this part of the task on a much better method. Le Clerc also published an account of certain worms occurring in men and animals.

LE DRAN, Henry Francis, was born at Paris in 1685, and educated under his father, who had acquired reputation as an operator, particularly in removing cancers of the breast. The young surgeon turned his attention principally to lithotomy, which he performed in the lateral method, and made some valuable improvements; which he communicated to the public in 1730, giving an accurate description of the parts: the work was favourably received, has been frequently reprinted, and translated into most modern languages. His surgical observations contain also much valuable practical matter: and his Treatise on Gun-shot Wounds is remarkable for the bold and successful measures which he adopted. He published likewise a Treatise on Operations, another called Surgical Consultations, and sent several papers of considerable merit to the academy of surgeons, which appear in their memoirs. He died in 1770.

LE'DUM. (A name adopted from the Greeks, whose ληδον is generally believed to be a species of *Cistus.*) The name of a genus of plants in the Linnæan system. Class, *Decandria;* Order, *Monogynia.*

Ledum palustre. The systematic name of the *Rosmarinus sylvestris*, and *Cistus ledon* of the shops. The plant has a bitter subastringent taste, and was formerly used in Switzerland in the place of hops. Its medicinal use is confined to the Continent, where it is occasionally given in the cure of hooping-cough, sore throat, dysentery, and exanthematous diseases.

LEECH. *Hirudo.* A genus of insects of the order *Vermes.* The body moves either forward or backward. There are several species, principally distinguished by their colour; but that most known to medical men is the *hirudo medicinalis*, or medicinal leech, which grows to the length of two or three inches. The body is of a blackish brown colour, marked on the back with six yellow spots, and edged with a yellow line on each side; but both the spots and lines grow faint, and almost disappear at some seasons. The head is smaller than the tail, which fixes itself very firmly to any thing the creature pleases. It is viviparous, and produces but one young one at a time, which is in the month of July. It is an inhabitant of clear running waters, and is well known for its use in bleeding. The species most nearly approaching this, and which it is necessary to distinguish, is the *hirudo sanguisuga*, or horse-leech. This is larger than the former; its skin is smooth and glossy; the body is depressed, the back is dusky; and the belly is of a yellowish green, having a yellow lateral margin. It inhabits stagnant waters.

The leech's head is armed with a sharp instrument that makes three wounds at once. They are three sharp tubercles, strong enough to cut through the skin of a man, or even of an ox, or horse. The mouth is, as it were, the body of the pump, and the tongue, or fleshy nipple, the sucker. By the working of this piece of mechanism, the blood is made to rise up to the conduit which conveys it to the animal's stomach, which is a membranaceous skin, divided into twenty-four small cells. The blood which is sucked out is there preserved for several months, almost without coagulating, and proves a store of provision to the animal. The nutritious parts, absorbed after digestion by animals, need not in this to be disengaged from the heterogeneous substances; nor indeed is there an anus discoverable in the leech; mere transpiration seems to be all that it performs, the matter fixing on the surface of the body, and afterwards coming off in small threads. On this, an experiment may be tried, by putting a leech into oil, where it keeps alive for several days; upon being taken out, and put into water, there appears to loosen from its body a kind of slough, shaped like the creature's body. The organ of respiration, though unascertained, seems to be situated in the mouth; for if, like an insect, it drew breath through vent-holes, it would not subsist in oil, as by it, these would be stopped up.

The *hirudo medicinalis* is the only species used in medicine; being applied to the skin in order to draw off blood. With this view, they are employed to bleed young children, and for the purposes of topical bleeding, in cases of inflammation, fulness, or pain. They may be employed in every case where topical bleedings are thought necessary, or where venesection cannot be performed. If the leech does not fasten, a drop of sugared milk is put on the spot it is wished to fix on, or a little blood is drawn by means of a slight puncture; after which it immediately settles. The leech, when fixed, should be watched, lest it should find its way into the anus, when used for the hæmorrhoids, or penetrate into the œsophagus, if employed to draw the gums; otherwise it might fix upon the stomach, or intestines. In such a case, the best and quickest remedy is to swallow some salt; which is the method practised to make it loose its hold, when it sucks longer than is intended. Vegetable or volatile alkali, pepper, or acids, also make it leave the part on which it was applied. Cows and horses have been known to receive leeches, when drinking, into the throat; and the usual remedy is to force down some salt, which makes them fall off. If it is intended that the leech shall draw a larger quantity of blood, the end of the tail is cut off; and it then sucks continually, to make up the loss it sustains. The discharge occasioned by the puncture of a leech after the animal falls off, is usually of more service than the process itself. When too abundant, it is easily stopped with brandy, vinegar, or other styptics, or with a compress of dry linen rags, bound strongly on the bleeding orifice. They are said to be very restless before a change of weather, if confined in glasses, and to fix themselves above the water on the approach of a fine day.

As these little animals are depended on for the removal of very dangerous diseases, and as they often seem capriciously determined to resist the endeavours made to cause them to adhere, the following directions are added, by which their assistance, may, with more certainty, be obtained.

The introducing a hand, to which any ill-flavoured medicine adheres, into the water, in which they are kept, will be often sufficient to deprive them of life; the application of a small quantity of any saline matter to their skin, immediately occasions the expulsion of the contents of their stomach; and what is most to our purpose, the least flavour of any medicament that has been applied remaining on the skin, or even the accumulation of the matter of perspiration, will prevent them from fastening. The skin should therefore, previous to their application, be very carefully cleansed from any foulness, and moistened with a little milk. The method of applying them is by retaining them to the skin by a small wine-glass, or the bottom of a large pill-box, when they will in general, in a little time, fasten themselves to the skin. On their removal, the rejection of the blood they have drawn may be obtained by the application of salt externally: but it is to be remarked, that a few grains of salt are sufficient for this purpose; and that covering them with it, as is sometimes done, generally destroys them.

LEEK. See *Allium porrum.*

Le′gna. (From λεγνον, a fringed edge.) The extremities of the pudenda muliebria.

LEGU′MEN. (From *lego*, to gather; so called because they are usually gathered by the hand.) A legume. A peculiar solitary fruit of the pea kind, formed of two oblong valves, without any longitudinal partition, and bearing the seeds along one of its margins only.

From the figure, the legumen is called,

1. *Teres*, round; as in *Phaseolus radiatus.*
2. *Lineare;* as in *Phaseolus vexillatus.*
3. *Compressum;* as in *Pisum sativum.*
4. *Capitatum;* as in *Phaseolus mungo.*
5. *Aciniforme;* as in *Phaseolus lunatus.*
6. *Ovatum;* as in *Lotus hirsutus*, and *græcus.*
7. *Inflatum*, a cavity filled with air; as in *Astragalus vesicarius*, and *exscapus.*
8. *Cochleatum*, spiral; as in *Medicago polymorpha*, and *marina.*
9. *Lunatum;* as in *Medicago falcata.*
10. *Obcordatum;* as in *Polygala.*
11. *Contortum;* as in *Medicago sativa.*
12. *Quadrangulatum;* as in *Dolychos tetragonolobus.*
13. *Canalicutatum*, the upper suture deeply hollowed; as in *Lathyrus sativus.*
14. *Isthmis interceptum*, as in *Coronilla.*
15. *Echinatum;* as in *Glycyrrhiza echinata.*
16. *Rhombeum;* as in *Cicer arietinum.*

From its insertion,

1. *Pendulum;* as in *Phaseolus vulgaris.*
2. *Pedicellatum;* as in *Viscia sæpium.*

From its substance,

1. *Membranaceum;* as in *Phaseolus vulgaris.*
2. *Carnosum;* as in *Cynometra cauliflora.*
3. *Coriaceum*, dry and fleshy; as in *Ceratonia siliqua*, and *Lupinus.*

From the number of seeds,

1. *Monospermum;* as in *Medicago lupulina.*
2. *Dispermum;* as in *Glycine tomentosa.*
3. *Trispermum;* as in *Trifolium reflexum.*
4. *Tetraspermum;* as in *Trifolium repens.*
5. *Polyspermum;* as in *Trifolium lupinaster.*

LEGUMINOUS. Appertaining to a legume.

Lei′chen. See *Lichen.*

Leiente′ria. See *Lienteria.*

LEIPOPSY′CHIA. (From λειπω, to leave, and ψυχη, life.) A swoon. See *Syncope.*

Leipopy′ria. (From λειπω, to leave, and πυρ, heat.) An ardent fever, in which the internal parts are much heated, while the external parts are cold.

LEIPOTHY′MIA. (From λειπω, to leave, and ϑυμος, the mind.) See *Lipothymia.*

Le′me. (From λα, much, and μυω, to wink.) A constant winking of the eyes.

LEMERY, Nicholas, was born at Rouen in 1645, and brought up to the business of pharmacy. He went to Paris at the age of 21 to improve himself, particularly in chemistry; and then travelled for some years: after which, in 1672, he began to give chemical lectures at Paris, and became very popular. Three years after he published his "Cours de Chymie," which passed rapidly through numerous editions; and so great was his reputation, that he acquired a fortune by the sale of his preparations, some of which he kept secret. In 1681, he was interdicted from lecturing on account of his religious principles, and took shelter in this country; but shortly after obtained the degree of doctor of physic at Caen, and got considerable practice in the French metropolis; the revocation of the edict of Nantes, however, forbidding this employment also, he was reduced to such difficulties, that he at length adopted the Catholic religion. He then flourished again, and in 1697 published his "Pharmacopée Universelle," followed the year after by his "Dictionnaire Universel des Drogues simples," which, though with many imperfections, proved of considerable utility. On the re-establishment of the Academy of Sciences, he was made associate chemist, and read before that body his papers on antimony, which were printed in 1707. He died in 1715.

LEMERY, Louis, son of the preceding, was born at Paris in 1677, and intended for the law, but adopted such a partiality for his father's pursuits, that he was allowed to indulge it, and graduated in his native city in 1796. Two years after he was admitted into the Academy of Sciences, and in 1708 began to lecture on chemistry, in the royal garden: he was appointed physician to the Hotel Dieu in 1710; and twelve years after purchased the office of King's physician, which soon led to the appointment of consulting physician to the Queen of Spain. In 1731 he was appointed professor of chemistry in the royal garden; and subsequently communicated several papers to the Academy of Sciences, which appeared in their Memoirs. He published also "Traité des Aliments," which was frequently reprinted; "A Dissertation on the Nourishment of Bones, refuting the Idea of its being effected by the Marrow;" and "Three Letters on the Generation of Worms." He died in 1743.

Lemithocho′rton. See *Corallina corsicana.*

Le′mma. (From λεπω, to decorticate.)

1. The bark of a tree.
2. The skin.

Le′mnius. (From *Lemnos*, whence it is brought.) See *Bole.*

LEMON. See *Citrus.*

Lemon scurvy-grass. See *Cochlearia officinalis.*

LENIE′NTIA. (From *lenio*, to assuage.) Medicines which abate irritation.

LENITIVE. (From *lenis*, gentle.) Medicines which gently palliate diseases. A gentle purgative.

Lenitive electuary. A preparation composed chiefly of senna and some aromatics, with the pulp of tamarinds. See *Confectio sennæ.*

LENS. (A *lentore;* from its glutinous quality.) 1. The lentil. See *Ervum lens.*

2. See *Crystalline lens.*

LENTICULA. (Dim. of *lens*, a lentil.)

1. A smaller sort of lentil.
2. A freckle, or small pustule, resembling the seeds of lentil.

LENTICULAR. (*Lenticularis;* from *lenticulaire*, doubly convex.) A surgical instrument employed for removing the jagged particles of bone from the edge of the perforation made in the cranium with the trephine.

LENTICULA′RIA. (From *lenticula.*) A species of lentil.

LENTI′GO. (From *lens*, a lentil: so named from its likeness to lentil-seeds.) A freckle on the skin.

LENTIL. An annual vegetable of the pulse kind, much used for improving the flavour of soups. See *Ervum lens.*

LENTI'SCUS. (From *lentesco*, to become clammy: so called from the gumminess of its juice.) The mastich-tree.

LE'NTOR. (From *lentus*, clammy.) A viscidity or siziness of any fluid.

LEONI'NUS. (From *leo*, the lion.) An epithet of that sort of leprosy called leontiasis.

LEONTI'ASIS. (From λεων, a lion: so called because it is said lions are subject to it.) A species of leprosy resembling the elephantiasis.

LEO'NTODON. (From λεων, the lion, and οδους, a tooth: so called from its supposed resemblance.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Polygamia æqualis.* The dandelion.

LEONTODON TARAXACUM. *Dens leonis.* The dandelion or pissabed. *Leontodon—caule squamis inferne reflexis, foliis runcinatis, denticulatis, lævibus,* of Linnæus. The young leaves of this plant in a blanched state have the taste of endive, and make an excellent addition to those plants eaten early in the spring as salads; and Murray informs us, that at Goettingen, the roots are roasted and substituted for coffee by the poorer inhabitants, who find that an infusion prepared in this way can hardly be distinguished from that of the coffee-berry. The expressed juice of dandelion is bitter and somewhat acrid; but that of the root is bitterer, and possesses more medicinal power than any other part of the plant. It has been long in repute as a detergent and aperient, and its diuretic effects may be inferred from the vulgar name it bears in most of the European languages, *quasi lecti minga et urinaria herba dicitur;* and there are various proofs of its efficacy in jaundice, dropsy, consumption, and some cutaneous disorders. The leaves, roots, flowers, stalks, and juice of dandelion, have all been separately employed for medical purposes, and seem to differ rather in degree of strength than in any essential property; therefore the expressed juice, or a strong decoction of the roots have most commonly been prescribed, from one ounce to four, two or three times a day. The plant should be always used fresh; even extracts prepared from it appear to lose much of their power by keeping.

LEONTOPO'DIUM. (From λεων, a lion, and πους, a foot: so named from its supposed resemblance.) The herb lion's foot, or *Filago leontopodium.*

LEONU'RUS. (From λεων, a lion, and ουρα, a tail: so named from its likeness.) 1. The name of a genus of plants in the Linnæan system. Class, *Didynamia;* Order, *Gymnospermia.* Lion's tail.

2. The name, in some pharmacopœias, for the lion's tail. See *Leonurus cardiaca.*

LEONURUS CARDIACA. The mother-wort. *Agripalma gallis; Marrubium; Cardiaca crispa; Leonurus—foliis caulinis lanceolatis, trilobis* of Linnæus. The leaves of this plant have a disagreeable smell and a bitter taste, and are said to be serviceable in disorders of the stomachs of children, to promote the uterine discharge, and to allay palpitation of the heart.

Leopard's bane. See *Arnica montana.*

LEPI'DIUM. (From λεπις, a scale: so named from its supposed usefulness in cleansing the skin from scales and impurities.) The name of a genus of plants in the Linnæan system. Class, *Tetradynamia;* Order, *Siliculosa.*

LEPIDIUM IBERIS. *Iberis; Cardamantica.* Sciatica cresses. This plant possesses a warm, penetrating, pungent taste, like unto other cresses, and is recommended as an antiscorbutic, antiseptic, and stomachic.

LEPIDIUM SATIVUM. *Nasturtium hortense.* Dittander. This plant possesses warm, nervine, and stimulating qualities, and is given as an antiscorbutic, antiseptic, and stomachic, especially by the lower orders.

LEPIDOSARCO'MA. (From λεπις, a scale, and σαρξ, flesh.) A scaly tumour.

LEPIDOSES. (From λεπις-δος, *squamma,* a scale.) The name of a genus of diseases. Class, *Eccritica;* Order, *Acrotica;* in Good's Nosology. Scale-skin. It contains four species, *Lepidosis pityriasis, lepriasis, psoriasis, icthyasis.*

LE'PISMA. (From λεπιζω, to decorticate.) Decortication. A peeling off of the skin.

LEPORINUS. (From *lepus*, a hare.) Leporine, or hare-like. Applied to some malformations, diseases, and parts, from their resemblance to *labium leporinum,* &c.

LE'PRA. (From λεπρος, *scaber, vel asper ex squammatis decedentibus;* named from its appearance.) The leprosy. A disease in the class *Cachexiæ,* and order *Impetigines* of Cullen. Dr. Willan describes this disease as characterised by scaly patches, of different sizes, but having always nearly a circular form. In this country, three varieties of the disease are observed, which he has described under the names of *Lepra vulgaris, Lepra alphos, Lepra nigricans.*

1. The *Lepra vulgaris* exhibits first small distinct elevations of the cuticle, which are reddish and shining, but never contain any fluid; these patches continue to enlarge gradually, till they nearly equal the dimensions of a crown-piece. They have always an orbicular, or oval form; are covered with dry scales, and surrounded by a red border. The scales accumulate on them, so as to form a thick prominent crust, which is quickly re-produced, whether it fall off spontaneously, or may have been forcibly detached. This species of lepra sometimes appears first at the elbow, or on the fore-arm; but more generally about the knee. In the latter case, the primary patch forms immediately below the patella; within a few weeks, several other scaly circles appear along the fore-part of the leg and thigh, increasing by degrees, till they come nearly into contact. The disease is then often stationary for a considerable length of time. If it advance further, the progress is towards the hip and loins; afterwards to the sides, back, shoulders, and about the same time, to the arms and hands. In the greater number of cases, the hairy scalp is the part last affected; although the circles formed on it remain for some time distinct, yet they finally unite, and cover the whole surface on which the hair grows with a white scaly incrustation. This appearance is attended, more especially in hot weather, with a troublesome itching and with a watery discharge for several hours, when any portion of the crust is detached, which takes place from very slight impressions. The pubes in adults is sometimes affected in the same manner as the head: and if the subject be a female, there is usually an internal *pruritus pudendi.* In some cases of the disorder, the nails, both of the fingers and toes, are thickened, and deeply indented longitudinally. When the lepra extends universally, it becomes highly disgusting in its appearance, and inconvenient from the stiffness and torpor occasioned by it in the limbs. The disease, however, even in this advanced stage, is seldom disposed to terminate spontaneously. It continues nearly in the same state for several years, or sometimes during the

whole life of the person affected, not being apparently connected with any disorder of the constitution.

2. *Lepra alphos.* The scaly patches in the alphos are smaller than those of the lepra vulgaris, and also differ from them in having their central parts depressed or indented. This disorder usually begins about the elbow, with distinct, eminent asperities, of a dull red colour, and not much longer than papillæ. These, in a short time, dilate to nearly the size of a silver penny. Two or three days afterwards, the central part of them suffers a depression, within which small white powdery scales may be observed. The surrounding border, however, still continues to be raised, but retains the same size and the same red colour as at first. The whole of the fore-arm, and sometimes the back of the hand, is spotted with similar patches: they seldom become confluent, excepting round the elbow, which, in that case, is covered with an uniform crust. This affection appears in the same manner upon the joint of the knee, but without spreading far along the thigh or leg. Dr. Willan has seldom seen it on the trunk of the body, and never on the face. It is a disease of long duration, and not less difficult to cure than the foregoing species of lepra: even when the scaly patches have been removed by persevering in the use of suitable applications, the cuticle still remains red, tender, and brittle, very slowly recovering its usual texture. The alphos, as above described, frequently occurs in this country.

3. The *Lepra nigricans* differs little from the lepra vulgaris, as to its form and distribution. The most striking difference is in the colour of the patches, which are dark and livid. They appear first on the legs and fore-arms, extending afterward to the thighs, loins, neck, and hands. Their central part is not depressed, as in the alphos. They are somewhat smaller in size than the patches of the lepra vulgaris, and not only is the border livid or purplish, but the livid colour of the base likewise appears through the scaly incrustation, which is seldom very thick. It is further to be observed, that the scales are more easily detached than in the other forms of lepra, and that the surface remains longer excoriated, discharging lymph, often with an intermixture of blood, till a new incrustation forms, which is usually hard, brittle, and irregular. The lepra nigricans affects persons whose occupation is attended with much fatigue, and exposes them to cold or damp, and to a precarious or improper mode of diet, as soldiers, brewers, labourers, butchers, stage-coachman, scullermen, &c.; some women are also liable to it, who are habituated to poor living and constant hard labour.

LEPRA GRÆCORUM. The lepra vulgaris, alphos, and nigricans, have all been so denominated. See *Lepra.*

LEPRIASIS. (From λεπρος, *scaber.*) The specific name of a species of *leprosis* in Good's Nosology, which embraces the several kinds of leprosy.

LEPROSY. See *Lepra.*

LEPTU′NTICA. (From λεπτος, thin.) Attenuating medicines.

LEPTY′SMUS. (From λεπτος, slender.) Attenuation, or the making a substance less solid.

LEPUS. The name of a genus of animals of the order *Griles*, in the class *Mammalia.* The hare.

LEPUS CUNICULUS. The systematic name of the rabbit, the flesh of which, when young and tender, is easy of digestion.

LEPUS TIMIDUS. The systematic name of the common hare; the flesh of which is considered as a delicacy, and easy of digestion.

LE′ROS. (From ληρεω, to trifle.) A slight delirium.

LETHARGY. (*Lethargus*; from ληθη, forgetfulness; so called because with it the person is forgetful.) A heavy and constant sleep, with scarcely any intervals of waking; when awakened, the person answers, but ignorant or forgetful of what he said, immediately sinks into the same state of sleep. It is considered as an imperfect apoplexy, and is mostly symptomatic.

LETHE′A. The name of the poppy.

LETTUCE. See *Lactuca.*

LEUCACA′NTHA. (From λευκος, white, and ακανθα, a thorn; so named from its white-blossom.) The cotton-thistle.

LEUCA′NTHEMUM. (From λευκος, white, and ανθεμος, a flower: so called from its white floret.) See *Chrysanthemum leucanthemum.*

LEUCASMUS. (Λευκασμος, whiteness; so named from its appearance.) The specific name, *Epichrosis leucasmus*, veal skin, in Good's Nosology for the *Vitiligo* of Willan.

LEUCE. (Λευκος, white.) A species of leprosy. See *Alphus.*

LEUCELE′CTRUM. (From λευκος, white, and ηλεκτρον, amber.) White amber.

LEUCINE. (From λευκος, white; from its appearance.) The name given by Braconnot to a white pulverulent matter obtained by digesting equal parts of beef fibre and sulphuric acid together, and after separating the fat, diluting the acid mixture, and saturating with chalk, filtering and evaporating. A substance tasting like ozmazome is thus procured, which is to be boiled in different portions of alkohol. The alkoholic solutions, on cooling, deposit the white pulverulent matter, or *leucine.*

LEUCOLA′CHANUM. (From λευκος, white, and λαχανον, an herb: so named from its colour.) The *Valeriana sylvestris.*

LEUCO′MA. (From λευκος, white.) Leucoma and albugo are often used synonymously, to denote a white opacity of the cornea of the eye. Both of them, according to Scarpa, are essentially different from the nebula, for they are not the consequence of chronic ophthalmy, attended with varicose veins, and an effusion of a milky serum into the texture of the delicate continuation of the conjunctiva over the cornea, but are the result of violent acute ophthalmy. In this state, a dense coagulating lymph is extravasated from the arteries; sometimes superficially, at other times deeply into the substance of the cornea. On other occasions, the disease consists of a firm callous cicatrix on this membrane, the effect of an ulcer, or wound, with loss of substance. The term *albugo*, strictly belongs to the first form of the disease; *leucoma* to the last, more partiularly when the the opacity occupies the whole, or the chief part, of the cornea.

LEUCONYMPHÆ′A. (From λευκος, white, and νυμφαια, the water-lily.) See *Nymphæa alba.*

LEUCOPHA′GIUM. (From λευκος, white, and φαγω, to eat.) A medicated white food.

LEUCOPHLEGMA′SIA. (From λευκος, white, and φλεγμα, phlegm.) Leucophlegmatic. A tendency in the system to a dropsical state known by a pale colour of the skin, a flabby condition of the solids, and a redundency of serum in the blood.

LEUCO′PIPER. (From λευκος, white, and πεπερι, pepper.) White pepper. See *Piper nigrum.*

LEUCORRHŒ′A. (From λευκοσ, white, and

ρεω, to flow.) *Fluor albus.* The whites. A secretion of whitish or milky mucus from the vagina of women, arising from debility, and not from the venereal virus. This disease is marked by the discharge of a thin white or yellow matter from the uterus and vagina, attended likewise with some degree of fætor, smarting in making water, pains in the back and loins, anorexia and atrophy. In some cases, the disharge is of so acrid a nature, as to produce effects on those who are connected with the woman, somewhat similar to venereal matter, giving rise to excoriations about the glans penis and præputium, and occasioning a weeping from the urethra.

To distinguish leucorrhœa from gonorrhœa, it will be very necessary to attend to the symptoms. In the latter the running is constant, but in a small quantity: there is much ardor urinæ, itching of the pudenda, swelling of the labia, increased inclination to venery, and very frequently an enlargement of the glands in the groin; whereas in the former the discharge is irregular, and in considerable quantities, and is neither preceded by, nor accompanied with, any inflammatory affection of the pudenda.

Immoderate coition, injury done to the parts by difficult and tedious labours, frequent miscarriages, immoderate flowings of the menses, profuse evacuations, poor diet, an abuse of tea, and other causes, giving rise to general debility, or to a laxity of the parts more immediaty concerned, are those which usually produce the whites, vulgarly so called, from the discharge being commonly of a milky white colour.

Fluor albus in some cases, indicates that there is a disposition to disease in the uterus, or parts connected with it, especially where the quantity of the discharge is very copious, and its quality highly acrimonious. By some the disease has been considered as never arising from debility of the system, but as being always a primary affection of the uterus. Delicate women, with lax fibres, who remove from a cold climate to a warm one, are very apt to be attacked with it without the parts having previously sustained any kind of injury.

The disease shows itself by an irregular discharge from the uterus and vagina of a fluid which, in different women, varies much in colour, being either of a white, green, yellow, or brown hue. In the beginning it is, however, most usually white and pellucid, and in the progress of the complaint acquires the various discolourations, and different degrees of acrimony, from whence proceeds a slight degree of smarting in making water. Besides the discharge, the patient is frequently afflicted with severe and constant pains in the back and loins, loss of strength, failure of appetite, dejection of spirits, paleness of the countenance, chilliness, and languor. Where the disease has been of long continuance, and very severe, a slow fever, attended with difficult respiration, palpitations, faintings, and swellings of the lower extremities, often ensues.

A perfect removal of the disorder will at all times be a difficult matter to procure; but it will be much more so in cases of long standing, and where the discharge is accompanied with a high degree of acrimony. In these cases, many disorders, such as prolapsus uteri, ulcerations of the organ, atrophy and dropsy, are apt to take place, which in the end prove fatal.

Where the disease terminates in death, the internal surface of the uterus appears, on dissection, to be pale, flabby, and relaxed; and where organic affections have arisen, much the same appearances are to be met with as have been noticed under the head of menorrhagia.

LEUCO'RRHOIS. (From λευκος, white, and ρεω, to flow.) A discharge of mucus from the urethra or vagina.

LEVA'TOR. (From *levo*, to lift up.) A muscle the office of which is to lift up the part to which it is attached.

Levator anguli oris. *Abducens labiorum*, of Spigelius; *Elevator labiorum communis* of Douglas; *Caninus*, of Winslow; and *Sus maxillo labial*, of Dumas. A muscle situated above the mouth, which draws the corner of the mouth upwards, and makes that part of the cheek opposite to the chin prominent, as in smiling. It arises thin and fleshy from the hollow of the superior maxillary bone, between the root of the socket of the first grinder and the foramen infra orbitarium, and is inserted into the angle of the mouth and under lip, where it joins with its antagonist.

Levator ani. *Levator magnus, seu internus*, of Douglas; *Pubo coccigi annulaire*, of Dumas. A muscle of the rectum. It arises from the os pubis, within the pelvis, as far up as the upper edge of the foramen thyroideum, and joining of the os pubis with the os ischium, from the thin tendinous membrane that covers the obturator internus and coccygæus muscles, and from the spinous process of the ischium. From these origins all round the inside of the pelvis, its fibres run down like rays from the circumference to a centre, to be inserted into the sphincter ani, acceleratores urinæ, and anterior part of the two last bones of the os coccygis, surrounding the extremity of the rectum, neck of the bladder, prostate gland, and part of the vesiculæ seminales. Its fibres, joining with those of its fellow, form a funnel-shaped hole, that draws the rectum upwards after the evacuation of the fæces, and assists in shutting it. The elevatores ani also sustain the contents of the pelvis, and assist in ejecting the semen, urine, and contents of the rectum, and perhaps, by pressing upon the veins, contribute greatly to the erection of the penis.

Levator labii inferioris. A muscle of the mouth situated below the lips. *Levator menti*, of Albinus. *Incisivus inferior*, of Winslow. *Elevator labii inferioris proprius*, of Douglas. It arises from the lower jaw, at the roots of the alveoli of two incisor teeth and the cuspidatus, and is inserted into the under lip and skin of the chin.

Levator labii superioris alæque nasi. *Elevator labii superioris proprius*, of Douglas; *Incisivus lateralis et pyramidalis*, of Winslow. A muscle of the mouth and lips, that raises the upper lip towards the orbit, and a little outwards; it serves also to draw the skin of the nose upwards and outwards, by which the nostril is dilated. It arises by two distinct origins; the first, broad and fleshy, from the external part of the orbitar process of the superior maxillary bone, immediately above the foramen infra orbitarium; the second, from the nasal process of the superior maxillary bone, where it joins the os frontis. The first portion is inserted into the upper lip and orbicularis muscle, the second into the upper lip and outer part of the ala nasi.

Levator labii superioris proprius. *Musculus incisivus.* A muscle of the upper lip. It arises under the edge of the orbit, and is inserted into the middle of the lip.

Levator oculi. See *Rectus superior oculi.*

Levator palati. A muscle situated between the lower jaw and the os hyoides laterally. *Levator palati mollis*, of Albinus; *Petrosalpin-*

go-staphilinus, vel salpingo-staphilinus internus, of Winslow; *Salpingo-staphilinus*, of Valsalva; *Pterigo-staphilinus externus vulgo*, of Douglas; *Spheno-staphilinus*, of Cowper. It arises tendinous and fleshy from the extremity of the petrous portion of the temporal bone, where it is perforated by the Eustachian tube, and also from the membranous part of the same tube, and is inserted into the whole length of the velum pendulum palati, as far as the root of the uvula, and unites with its fellow. Its use is to draw the velum pendulum palati upwards and backwards, so as to shut the passage from the fauces into the mouth and nose.

LEVATOR PALATI MOLLIS. See *Levator palati.*

LEVATOR PALPEBRÆ SUPERIORIS. *Aperiens palpebrarum rectus; Apertor oculi.* A proper muscle of the upper eyelid, that opens the eyes, by drawing the eyelid upwards. It arises from the upper part of the foramen opticum of the spenoid bone, above the rectus superior oculi, near the trochlearis, and is inserted by a broad thin tendon into the cartilage that supports the upper eyelid.

LEVATOR PARVUS. See *Transverus perinei.*

LEVATOR SCAPULÆ. A muscle situated on the posterior part of the neck, that pulls the scapula upwards and a little forwards. This name, which was first given to it by Riolanus, has been adopted by Albinus. Douglas calls it *elevator seu musculus patientiæ*; and Winslow, *angularis, vulgo levator proprius.* It is a long muscle, nearly two inches in breadth, and is situated obliquely under the anterior edge of the trapezius. It arises tendinous and fleshy from the transverse processes of the four and sometimes five superior vertebræ colli, by so many distinct slips, which soon unite to form a muscle that runs obliquely downwards and outwards, and is inserted by a flat tendon into the upper angle of the scapula. Its use is to raise the scapula upwards and a little forwards.

LEVIGATION. (*Lævigatio; from lævigo*, to make smooth.) The reduction of a hard substance, by triture, to an impalpable powder.

LEVI'STICUM. (From *levo*, to assuage: so called from the relief it gives in painful flatulencies.) See *Ligusticum levisticum.*

LEVRET, ANDREW, a French surgeon and accoucheur, was admitted into the Royal Academy of Surgery at Paris in 1742. He obtained considerable reputation by the improvements, which he made in some of the instruments used in difficult cases, and by the great number of pupils whom he instructed. He was employed and honoured with official appointments by all the female branches of the Royal family. He published several works, which went through various editions and translations, mostly on obstetrical subjects; but there is one on the Radical Cure of Polypi in different parts of the body.

LEXIPHA'RMACA. (From ληξω, to terminate, and φαρμακον, poison.) Medicines which resist or destroy the power of poison.

LEXIPY'RETA. (From ληγω, to make cease, and πυρετος, a fever.) Febrifuge medicines.

LIBA'DIUM. (From λιβαζω, to make moist: so called because it grows in watery places.) The lesser centaury. See *Chironia centaurium.*

LIBANO'TIS. (From λιβανος, frankincense: so called from its resemblance in smell to frankincense.) Rosemary.

LI'BANUS. (From *Libanon*, a mountain in Syria, where it grows.) 1. The *Pinus cedrus*, or cedar of Lebanon.

2. The frankincense tree, or *Pinus abies.*

LIBER. Bark. Immediately under the cuticle of plants and trees is a succulent cellular substance, for the most part of a green colour, at least of the leaves and branches, called by Du Hamel *enveloppe cellulaire*, and by Mirbel *tissue herbacé.* Under this is the bark, consisting of but one layer in plants or branches only one year old. In the older branches and trunks of trees, it consists of as many layers as they are years old, the innermost being called the *liber*, and it is this layer only that the essential vital functions are carried on for the time being, after which it is pushed outwards with the cellular integument, and becomes, like that, a lifeless crust. —*Smith.*

LI'BOS. (From λειβω, to distil.) A rheum or defluxion from the eyes, or nose.

LIBU'RNUM. (From *Liburnia*, the country where it flourished.) The mealy-tree. See *Viburnum lantana.*

LICETO, FORTUNIO, was son of a Genoese physician, and born in 1577. After prosecuting with diligence the requisite studies, he settled at Pisa at the age of twenty-two, and soon obtained the professorship of philosophy there; and in 1609 he received a similar appointment at Padua. Thence, after twenty-seven years, he removed to Bologna, being disappointed of the medical chair; but on a vacancy occurring in 1645, he was induced, by the pressing invitations made to him, to accept the office, in which he continued till his death in 1657. He was a very copious writer, having published above fifty treatises on different subjects, and displayed much erudition; but no great acuteness or originality. His treatise "De Monstrorum Causis, Natura, et Differentiis," is best known, and shows him to have been very credulous; which appears farther from his belief, that the ancients had a method of making lamps, which should burn for ever without a fresh supply of fuel, and that such had been found in sepulchres.

LI'CHANUS. (From λειχω, to lick: so called because it is commonly used in licking up any thing.) The fore-finger.

LI'CHEN. (Λειχην, or λιχην, a tetter or ring worm.) Tetter or ring-worm.

1. The name of a disease, defined, by Dr. Willan, an extensive eruption of papulæ affecting adults, connected with internal disorder, usually terminating in scurf, recurrent, not contagious. The varieties of lichen he considers under the denominations of *Lichen simplex, Lichen agrius, Lichen pilaris, Lichen lividus*, and *Lichen tropicus.*

The *Lichen simplex* usually commences with headache, flushing of the face, loss of appetite, general languor, and increased quickness of the pulse. Distinct red papulæ arise first about the cheeks and chin, or on the arms; and, in the course of three or four days, the same appearance takes place on the neck, body, and lower extremities, accompanied with an unpleasant sensation of tingling, which is somewhat aggravated during the night. In about a week, the colour of the eruption fades, and the cuticle begins to separate; the whole surface is at length covered with scurfy exfoliations, which are particularly large, and continue longest in the flexures of the joints. The duration of the complaint is seldom in any two cases alike; ten, fourteen, seventeen, or sometimes twenty days intervene betwixt the eruption and the renovation of the cuticle. The febrile state, or rather the state of irritation at the beginning of this disorder, is seldom considerable enough to confine the patient to the house. After remaining five or six days, it is generally relieved on the appearance of the eruption. This, as well as some other species of the lichen, occurs about the beginning of summer, or in autumn, more especially affecting persons of a weak and irritable habit; hence women are more liable to it than men. Lichen simplex is also a frequent sequel of acute diseases, particularly fever and catarrhal inflammation, of which it seems to produce a crisis. In these cases the eruption has been termed, by medical writers, scabies critica. Many instances of it are collected under that title by Sauvages, Nosol. Method. Class x. Order 5. *Impetigines.*

The *Lichen agrius* is preceded by nausea, pain in the stomach, headache, loss of strength, and deep-seated pains in the limbs, with fits of coldness and shivering; which symptoms continue several days, and are sometimes relieved by the papulous eruption. The papulæ are distributed in clusters, or often in large patches, chiefly on the arms, the upper part of the breast, the neck, face, back, and sides of the abdomen; they are of a vivid red colour, and have a redness, or some degree of inflammation, diffused round them to a considerable extent, and attended with itching, heat, and a painful tingling. Dr. Willan has observed, in one or two cases where it was produced from imprudent exposure to cold, that an acute disease ensued, with great quickness of the pulse, heat, thirst, pains of the bowels, frequent vomiting, headache, and delirium. After these symptoms had continued ten days, or somewhat longer, the patient recovered, though the eruption did not return. The diffuse redness connecting the papulæ, and the tendency to become pustular distinguish the lichen agrius from the lichen simplex, and the other varieties of this complaint, in which the inflammation does not extend beyond the basis of the papulæ, and terminates in scurf, or scales.

Lichen pilaris. This is merely a modification of the first species of lichen, and, like it, often alternates with complaints of the head, or stomach, in irritable habits. The peculiarity of the eruption is, that the small tubercles or asperities appear only at the roots of the hairs of the skin, being probably occasioned by an enlargement of their bulbs, or an unusual fulness of the blood-vessels distributed to them. This affection is distinguishable from the cutis anserina, by its permanency, by its red papulæ, and by the troublesome itching or tingling which attends it. If a part thus affected be violently rubbed, some of the papulæ enlarge to the size of wheals, but the tumour soon subsides again. The eruption continues more or less vivid for about ten days, and terminates, as usual, in small exfoliations of the cuticle, one of which surrounds the base of each hair. This complaint, as likewise the lichen agrius, frequently occurs in persons accustomed to drink largely of spirituous liquors undiluted.

Lichen lividus. The papulæ characterising this eruption are of a dark red, or livid hue, and somewhat more permanent than in the foregoing species of lichen. They appear chiefly on the arms and legs, but sometimes extend to other parts of the body. They are finally succeeded, though at very uncertain periods, by slight exfoliations of the cuticle, after which a fresh eruption is not preceded nor attended by any febrile symptoms. It principally affects persons of a weak constitution, who live on a poor diet, and are engaged in laborious occupations. Young persons, and often children living in confined situations, or using little exercise, are also subject to the lichen lividus; and in them, the papulæ are generally intermixed with petechiæ, or larger purple spots, resembling vibices. This circumstance points out the affinity of the lichen lividus with the purpura, or land-scurvy, and the connexion is further proved by the exciting causes, which are the same in both complaints. The same method of treatment is likewise successful in both cases. They are presently cured by nourishing food, moderate exercise in the open air, along with the use of Peruvian bark and vitriolic acid, or the tincture of muriated steel.

Lichen tropicus. By this term is expressed the prickly heat, a papulous eruption, almost universally affecting Europeans settled in tropical climates. The prickly heat appears without any preceding disorder of the constitution. It consists of numerous papulæ, about the size of a small pin's head, and elevated so as to produce a considerable roughness on the skin. The papulæ are of a vivid red colour, and often exhibit an irregular form, two or three of them being in many places united together; but no redness or inflammation extends to the skin in the interstices of the papulæ.

2. The name of a genus of plants (applied by the Romans to a plant which was supposed by them to cure the lichen or tetter,) in the Linnæan system. Class, *Cryptogamia;* Order, *Algæ.* There are several species, some of which are used in medicine.

LICHEN APHTHOSUS. *Muscus camatilis.* This plant is said to have a decided good effect in some complaints of the intestines, but is not used in the practice of this country.

LICHEN CANINUS. The systematic name of the ash-coloured ground liver-wort. *Lichen cinereus terrestris; Muscus caninus.* This cryptogamous plant has a weak, faint smell, and a sharpish taste. It was for a long time highly extolled as a medicine of singular virtue, in preventing and curing that dreadful disorder which is produced by the bite of rabid animals, but it is now deservedly forgotten.

LICHEN CINEREUS TERRESTRIS. See *Lichen caninus.*

LICHEN COCCIFERUS. See *Lichen pyxidatus.*

LICHEN ISLANDICUS. The medicinal qualities of this plant have lately been so well established at Vienna, that it is now admitted into the materia medica of the London Pharmacopœia. It is extremely mucilaginous, and to the taste bitter, and somewhat astringent. Its bitterness, as well as the purgative quality which it manifests, in its recent state, are in a great measure dissipated on drying, or may be extracted by a slight infusion in water; so that the inhabitants of Iceland convert it into a tolerably grateful and nutritive food. An ounce of this lichen, boiled a quarter of an hour in a pint of water, yielded seven ounces of a mucilage as thick as that procured by the solution of one part of gum-arabic in three of water.

The medical virtues of this lichen were probably first learned from the Icelanders, who employ it in its fresh state as a laxative; but when deprived of this quality, and properly prepared, we are told that it is an efficacious remedy in consumptions, coughs, dysenteries, and diarrhœas. Scopoli seems to have been the first who, of late years, called the attention of physicians to this remedy in consumptive disorders: and further instances of its success are related by Herz, Cramer, Tromsdorff, Ebeling, Paulisky, Stoll, and others, who bear testimony to its efficacy in most of the other complaints above-mentioned. Dr. Herz says, that since he first used the lichen in dysentery, he found it so successful, that he never had occasion to employ any other remedy; it must be observed, however, that cathartics and emetics were always repeatedly administered before he had recourse to the lichen, to which he also occasionally added opium. Dr. Crichton informs us, that during seven months' residence at Vienna, he had frequent opportunities of seeing the lichen islandicus tried in phthisis pulmonalis at the general hospitals, and confesses, "that it by no means answered the expectation he had formed of it." He adds, however, "from what I have seen, I am fully convinced in my own mind, that there are only two species of this disease where this sort of lichen promises a cure. The two species I hint at are the phthisis hæmoptoica, and the phthisis pituitosa, or mucosa. In several cases of these, I have seen the patients so far get the better of their complaints as to be dismissed the hospital cured, but whether they remained long so or not I cannot take upon me to say." That this lichen strengthens the digestive powers, and proves extremely nutritious, there can be no doubt; but the great medicinal efficacy attributed to it at Vienna, will not readily be credited at London. It is commonly given in the form of a decoction: an ounce and a half of the lichen being boiled in a quart of milk. Of this, a tea-cupful is directed to be drank frequently in the course of the day. If milk disagree with the stomach, a simple decoction of the lichen in water is to be used. Care ought to be taken that it be boiled over a slow fire, and not longer than a quarter of an hour.

Lichen plicatus. The systematic name of the *muscus arboreus.* This plant, we are informed by that great botanist Linnæus, is applied by the Laplanders to parts which are excoriated by a long journey. It is slightly astringent, and is applied with that intention to bleeding vessels.

Lichen pulmonarius. The systematic name of the officinal *muscus pulmonarius quercinus. Pulmonaria arborea.* This subastringent, and rather acid plant, was once in high estimation in the cure of diseases of the lungs, especially coughs, asthmas, and catarrhs. Its virtues are similar, and in no way inferior to those of the lichen islandicus.

Lichen pyxidatus. The systematic name of the cup-moss. *Muscus pyxidatus; Musculus pyxoides terrestris; Lichen pyxidatus major.* These very common little plants, *Lichen cocciferus,* and *pyxidatus,* of Linnæus, for both are used indifferently, are employed by the common people in this country in the cure of hooping-cough, in the form of decoction.

Lichen roccella. The systematic name of the roccella of the shops. *Roccella.* It has been employed medicinally with success in allaying the cough attendant on phthisis, and in hysterical coughs. The principal use is as a blue dye. It is imported to us as it is gathered: those who prepare it for the use of the dyer, grind it betwixt stones, so as thoroughly to bruise, but not to reduce it into powder, and then moisten it occasionally with a strong spirit of urine, or urine itself mixed with quicklime: in a few days it acquires a purplish red, and at length a blue colour; in the first state it is called archil, in the latter lacmus or litmus.

Litmus is used in chemistry as a test, either staining paper with it, or by infusing it in water, when it is very commonly, but with great impropriety, called *tincture of turnsole.* The person by whom this article was prepared formerly, gave it the name of turnsole, pretending that it was extracted from the turnsole, *heliotropium tricoccum,* in order to keep its true source a secret. The tincture should not be too strong, otherwise it will have a violet tinge, which, however, may be removed by dilution. The light of the sun turns it red even in close vessels. It may be made with spirit instead of water. This tincture, or paper stained with it, is presently turned red by acids: and if it be first reddened by a small quantity of vinegar, or some weak acid, its blue colour will be restored by an alkali.

Lichen saxatilis. The systematic name of the *muscus cranii humani. Usnea.* This moss, when growing on the human skull, was formerly in high estimation, but is now deservedly forgotten.

LI'EN. (From λειος, soft, or smooth.) The spleen. See *Spleen.*

Lien sinarum. The faba Ægyptia. See *Nymphæa nelumbo.*

LIENTE'RIA. (From λειος, smooth, and εντερον, the intestine.) Lientery. See *Diarrhœa.*

LIEUTAUD, Joseph, was born at Aix, in Provence, in 1703. A taste for botany induced him to travel into the countries which Tournefort had visited: and he brought back many plants unnoticed by that distinguished botanist: this gained him great applause, and he obtained the reversion of the chairs of Botany and Anatomy, which his maternal uncle had long filled. He was also appointed physician to the hospital at Aix, which led him to turn his attention chiefly to Anatomy. His audience soon became numerous, and in 1742 he published a syllabus, entitled "Essais Anatomiques," which was many times reprinted, with improvements. He communicated also several papers on morbid anatomy, and on physiology, to the Academy of Sciences, of which he was elected a corresponding member. In 1749 he went to Versailles, Senac having obtained for him the appointment of physician to the Royal Infirmary; which act of friendship is ascribed to a liberal private communication of some errors committed by Senac. He there continued his investigations with great zeal, and was soon elected assistant anatomist to the Royal Academy, which he presented with many valuable memoirs. He also printed a volume, "Elementa Physiologiæ," composed for his class at Aix. In 1755 he was nominated physician to the royal family, and 20 years after first physician to Louis XVI. In 1759 his "Précis de la Médecine Pratique," appeared, which went through several editions; and seven years after, his "Précis de la Matière Médicale." But his most important work, which still ranks high in the estimation of physicians, is entitled "Historia Anatomico-Medica," in 2 vols. quarto, 1767, containing numerous dissections of morbid bodies. His death occurred in 1780.

LIEVRITE. *Yenite.* A blackish-green-coloured mineral, composed of silica, alumina, lime, oxide of iron, and oxide of manganese, found in primitive limestone along with epidote, quartz, &c. in the isle of Elba.

LIFE. A peculiar condition or mode of existence of living beings. Surrounding matter is divided into two great classes, living and dead. The latter is subject to physical laws, which the former also obeys in a great degree. Living matter exhibits also physical properties, which are found equally in dead matter. But living bodies are endowed likewise with a set of properties altogether different from these, and contrasting with them in a very remarkable way; these are called vital properties, actions, powers, faculties or forces. These animate living matter so long as it continues alive, and are the source of the various phenomena which constitute the functions of the living animal body, and which distinguish its history from that of dead matter. The study of life is the object of the science of physiology, which includes an inquiry into the properties that characterise living matter, and an investigation of the functions which the various organs by virtue of these properties are enabled to execute. The vital principle diffused throughout these organs induces a mode of union in the elements, widely differing from that which arises from the common laws of chemical affinity. By the aid of this principle, nature produces the animal fluids, as blood, bile, semen, and the rest, which can never be produced by the art of chemistry. But if, in consequence of death, the laws of vital attraction, or affinity, cease to operate, then the elements, recovering their physical properties, become again obedient to the common laws of chemical affinity, and enter into new combinations, from which new principles, in the process of putrefaction, are produced. Thus the hydrogen, combining itself with the azote, forms volatile alkali; and the carburetted hydrogen, with the azote, putrid air, into which the whole body is converted. It also appears from hence, why organised bodies alone, namely, animal and vegetable, are subject to putridity; to which inorganic or mineral substances are in no degree liable, the latter not being compounded according to the laws of vital affinity, but only according to those of chemical affinity. For the fatiscence, or resolution of pyrites, or sulphuret of iron, in atmospheric air, is not putrefaction, but only the oxygen, furnished by the air, combining with the sulphur, and forming iron and sulphate of iron.

The life of an animal body appears to be threefold:

1. *Its chemical life*, which consists in that attraction of the elements, by which the vital principle, diffused through the solids and fluids, defends all the parts of the body from putrefaction. In this sense it may be said, that every atom of our body lives *chemically*, and that life is destroyed by putrefaction alone.

2. *Its physical life*, which consists in the irritability of the parts. This physical property remains for some time after death. Thus the heart or intestines removed from the body, whilst still warm, contract themselves on the application of a stimulus. In like manner the serpent or eel, being cut into pieces, each part moves and palpitates for a long time afterwards. Hence these parts may be said to live physically, as long as they are warm and soft.

3. *Its physiological life* consists in the action of inorganic parts proper to each, as the action of the heart and vessels: so that these actions ceasing, the body is said to be physiologically dead. The physiological life ceases first, next the physical, and finally the chemical perishes.

LIGAMENT. (*Ligamentum;* from *ligo*, to bind.) An elastic and strong membrane connecting the extremities of the moveable bones. Ligaments are divided into *capsular*, which surround joints like a bag, and *connecting* ligaments. The use of the capsular ligaments is to connect the extremities of the moveable bones, and prevent the efflux of synovia; the external and internal connecting ligaments strengthen the union of the extremities of the moveable bones.

LIGAMENTUM ANNULARE. The annular ligament. A strong ligament on each ankle and each wrist.

LIGAMENTUM ARTERIOSUM. The ductus arteriosus of the fœtus becomes a ligament after birth, which is so called.

LIGAMENTUM CILIARE. Behind the uvea of the human eye, there arise out of the choroid membrane, from the ciliary circle, white complicated striæ, covered with a black matter. The fluctuating extremities of these striæ are spread abroad even to the crystalline lens, upon which they lie, but are not affixed. Taken together, they are called *ligamentum ciliare.*

LIGAMENTUM DENTICULATUM. A small ligament supporting the spinal marrow.

LIGAMENTUM FALLOPII. The round ligament of the uterus has been so called. See also *Ligamentum Pouparti.*

LIGAMENTUM INTEROSSEUM. The ligament uniting the radius and ulna, and also that between the tibia and fibula.

LIGAMENTUM LATUM. The broad ligament of the liver, and that of the uterus. See *Liver* and *Uterus.*

LIGAMENTUM NUCHÆ. A strong ligament of the neck, which proceeds from one spinous process to another

LIGAMENTUM OVARII. The thick round portion of the broad ligament of the uterus, by which the ovarium is connected with the uterus.

LIGAMENTUM POUPARTI. Fallopian ligament. Poupart's ligament. A ligament extending from the anterior superior spinous process of the ilium to the crista of the os pubis.

LIGAMENTUM ROTUNDUM. The round ligament of the uterus. See *Uterus.*

LIGATURE. (*Ligatura;* from *ligo*, to bind.) A thread, or silk, of various thickness, covered with white wax, for the purpose of tying arteries, or veins, or other parts. Ligatures should be round and very firm, so as to allow their being tied with some force, without risk of breaking.

The immediate effect of a tight ligature on an artery is to cut through its middle and internal coats, a circumstance that tends very much to promote the adhesion of the opposite sides of the vessel to each other. Hence the form and mode of applying a ligature to an artery should be such as are most certain of dividing the above coats of the vessel in the most favourable manner. A broad flat ligature does not promise to answer the purpose in the best manner; because it is scarcely possible to tie it smoothly round the artery, which is very likely to be thrown into folds, or to be puckered by it, and consequently to have an irregular bruised wound made in its middle and internal coats. A ligature of an irregular form is likely to cut through these coats more completely at some parts than at others; and if it does not perfectly divide them no adhesion can take place, and secondary hæmorrhage will follow. A fear of tying the ligature too tight may often lead to the same consequences.

LIGHT. *Lux.* The nature of light has occupied much of the attention of philosophers, and numerous opinions have been entertained concerning it. It has been sometimes considered as a distinct substance, at other times as a quality; sometimes as a cause, frequently as an effect; by some it has been considered as a compound, by others as a simple substance. Philosophers of the present day are mostly agreed as to the independent existence of light, or the cause by which we see.

Nature of light.—Light is that which proceeds from any body producing the sensation of vision, or perception of other bodies, by depicting an image of external objects on the retina of the eye. Hence it announces to animals the presence of the bodies which surround them, and enables them to distinguish these bodies into transparent, opaque, and coloured. These properties are so essentially connected with the presence of light, that bodies lose them in the dark, and become undistinguishable.

Light is regarded by philosophers as a substance consisting of a vast number of exceedingly small particles, which are actually projected from luminous bodies,and which probably never return again to the body from which they were emitted. It is universally expanded through space. It exerts peculiar actions, and is obedient to the laws of attraction, and other properties of matter.

Explanation of certain terms of Light.—In order to facilitate the doctrine of light, we shall shortly explain a few terms made use of by philosophers when treating of it ; namely,

A *ray of light* is an exceedingly small portion of light as it comes from a luminous body.

A *medium* is a body which affords a passage for the rays of light.

A *beam of light* is a body of parallel rays.

A *pencil of rays* is a body of diverging or converging rays.

Converging rays are rays which tend to a common point.

Diverging rays are those which come from a point, and continually separate as they proceed.

The rays of light are *parallel*, when the lines which they describe are so.

The *radiant point* is the point from which diverging rays proceed.

The *focus* is the point to which the converging rays are directed.

Sources of light.—Light is emitted from the sun, the fixed stars, and other luminous bodies. It is produced by percussion, during electrisation, combustion, and in various other chemical processes.

Why the sun and stars are constantly emitting light, is a question which probably will for ever baffle human understanding.

The light emitted during combustion exists previously, either combined with the combustible body, or with the substance which supports the combustion. The light liberated during chemical action, formed a constituent part of the bodies which act on each other.

Chemical Properties of Light.—The chemical effects of light have much engaged the attention of philosophers. Its influence upon animal, vegetable, and other substances, is as follows :

1. *On vegetables.*—Every body knows that most of the discous flowers follow the sun in his course ; that they attend him to his evening retreat, and meet his rising lustre in the morning with the same unerring law. It is also well known that the change of position in the leaves of plants, at different periods of the day, is entirely owing to the agency of light, and that plants which grow in windows, in the inside of houses, are, as it were, solicitous to turn their leaves towards the light. Natural philosophers have long been aware of the influence of light on vegetation. It was first observed that plants growing in the shade, or darkness, are pale and without colour. The term, *etiolation*, has been given to this phenomenon, and the plants, in which it takes place, are said to be *etiolated*, or *blanched*. Gardeners avail themselves of the knowledge of this fact, to furnish our tables with white and tender vegetables. When the plants have attained a certain height, they compress the leaves, by tying them together, and by these means (or by laying earth over them,) deprive them of the contact of light. and thus it is that our white, celery, lettuce, cabbages, endive, &c. are obtained. For the same reason, wood is white under the green bark ; and roots are less coloured than plants ; some of them alter their taste, &c. ; they even acquire a deleterious quality when suffered to grow, exposed to light. Potatoes are of this kind. Herbs that grow beneath stones, or in places utterly dark, are white, soft, aqueous, and of a mild and insipid taste. The more plants are exposed to the light, the *more colour* they acquire. Though plants are capable of being nourished exceedingly well in the dark, and in that state grow much more rapidly than in the sun, (provided the air that surrounds them is fit for vegetation,) they are colourless and unfit for use.

Professor Davy found, by experiment, that red rose-trees, carefully excluded from light, produce roses almost white. He likewise ascertained that this flower owes its colour to light entering into its composition, that pink, orange, and yellow flowers imbibe a smaller portion of light than red ones, and that white flowers contain no light. But vegetables are not only indebted to the light for their colour : taste and odour are likewise derived from the same source.

Light contributes greatly to the maturity of fruits and seeds. This seems to be the cause why, under the burning sun of Africa, vegetables are in general more odoriferous, of a stronger taste, and more abounding with resin. From the same cause it happens, that hot climates seem to be the native countries of perfumes, odoriferous fruits, and aromatic resins.

The action of light is so powerful on the organs of vegetables, as to cause them to pour forth torrents of pure air from the surface of their leaves into the atmosphere, while exposed to the sun ; whereas, on the contrary, when in the shade, they emit an air of a noxious quality. Take a few handsful of fresh-gathered leaves of mint, cabbage, or any other plant ; place them in a bell-glass, filled with fresh water, and invert it into a bason with the same fluid. If the whole be then exposed to the direct rays of the sun, small air bubbles will appear on the surface of the leaves, which will gradually grow larger and at last detach themselves and become collected at the surface of the water. This is oxygen gas, or vital air.

All plants do not emit this air with the same facility ; there are some which yield it the moment the sun acts upon them ; as the jacobœa or rag-wort, lavender, peppermint, and some other aromatic plants. The leaves afford more air when attached to the plant than when gathered ; the quantity is also greater, the fresher and sounder they are, and if full grown and collected during dry weather. Green plants afford more air than those which are of a yellowish or white colour. Green fruits afford likewise oxygen gas ; but it is not so plentifully furnished by those which are ripe. Flowers in general render the air noxious. The Nasturtium indicum, in the space of a few hours, gives out more air than is equal to the bulk of all its leaves. On the contrary, if a like bell-glass, prepared in the same manner, be kept in the dark, another kind of air will be disengaged, of an opposite quality.

There is not a substance which, in well-closed glass vessels, and exposed to the sun's light, does not experience some alteration.

Camphor kept in glass bottles, exposed to light, crystallises into the most beautiful symmetrical figures, on that side of the glass which is exposed to the light.

Yellow wax, exposed to the light, loses its colour, and becomes bleached. Gum guiacum, reduced to powder, becomes green on exposure to light. Vegetable colours, such as those of saffron, logwood, &c. become pale, or white, &c.

2. *On animals.*—The human being is equally dependent on the influence of light. Animals in general droop when deprived of light, they become unhealthy, and even sometimes die. When a man has been long confined in a dark dungeon (though well aired,) his whole complexion becomes sallow; pustules, filled with aqueous humours, break out on his skin; and the person, who has been thus deprived of light, becomes languid, and frequently dropsical. Worms, grubs, and caterpillars, which live in the earth, or in wood, are of a whitish colour; moths, and other insects of the night, are likewise distinguishable from those which fly by day by the want of brilliancy in their colour. The difference between those insects, in northern and southern parts, is still more obvious.

The parts of fish which are exposed to light, as the back, fins, &c. are uniformly coloured, but the belly, which is deprived of light, is white in all of them.

Birds which inhabit the tropical countries have much brighter plumage than those of the north. Those parts of the birds which are not exposed to the light are uniformly pale. The feathers on the belly of a bird are generally pale, or white; the back, which is exposed to the light, is almost always coloured; the breast, which is particularly exposed to light in most birds, is brighter than the belly.

Butterflies, and various other animals of equatorial countries, are brighter coloured than those of the polar regions. Some of the northern animals are even darker in summer and paler in winter.

3. *On other substances.*—Certain metallic oxides become combustible when exposed to light; and acids, as the nitric, &c. are decomposed by its contact, and various other substances change their nature.

Light carbonated hydrogen. See *Carburetted hydrogen gas.*

LIGNEUS. Woody. Applied in botany to pods, barks, &c. which are of a hard membraneous, or woody texture; as the strobilus of the *Pinus sylvestris.*

LI'GNUM. Wood.

LIGNUM AGALLOCHI VERI. See *Lignum aloes.*

LIGNUM ALOES. *Lignum agallochi veri; Agalluge; Agallugum; Lignum aquilæ; Lignum calambac; Lignum aspalathi; Xylo aloes; Agallochum; Calambac.* Aloes-wood. The tree, the wood of which bears this name, is not yet scientifically known. It is by some supposed to be the *Excœaria agallocha*, the bark as well as the milk of which is purgative. It is imported from China in small, compact, ponderous pieces, of a yellow rusty brown colour, with black or purplish veins, and sometimes of a black colour. It has a bitterish resinous taste, and a slight aromatic smell. It is used to fumigate rooms in Eastern countries.

LIGNUM AQUILÆ. See *Lignum aloes.*

LIGNUM ASPALATHI. See *Lignum aloes.*

LIGNUM CALAMBAC. See *Lignum aloes.*

LIGNUM CAMPECHENSE. (*Campechensis:* so called because it was brought from Campeachy, in the bay of Honduras.) See *Hæmatoxylum campechianum.*

LIGNUM INDICUM. See *Guaiacum.*

LIGNUM MOLUCCENSE. See *Croton tiglium.*

LIGNUM NEPHRITICUM. See *Guilandina moringo.*

LIGNUM PAVANÆ. See *Croton tiglium.*

LIGNUM RHODIUM. See *Aspalathus Canariensis.*

LIGNUM SANCTUM. See *Guaiacum.*

LIGNUM SANTALI RUBRI. See *Pterocarpus santalinus.*

LIGNUM SAPPAN. See *Hæmatoxylon campechianum.*

LIGNUM SERPENTUM. See *Ophioxylum serpentinum.*

LIGULA. (*Ligula*, a strap.) 1. The clavicle.

2. The glottis.

3. The name of a measure and a weight.

4. A genus of the Mollusca order.

5. The small transparent membrane on the margin of the sheath and base of the leaves of grasses.

LIGULATUS. Shaped like a straw or riband: a term applied to a kind of floret of a compound flower, which is so shaped; as those of the *Tragopogon* and *Taraxacum.*

LIGUSTICUM. (Λιγυςικον of Dioscorides; so called from *Liguria*, in Italy, its native country.) The name of a genus of plants. Class, *Pentandria;* Order, *Digynia.*

LIGUSTICUM LEVISTICUM. The systematic name of lovage. *Levisticum.* The odour of this plant, *Ligusticum—foliis multiplicibus, foliolis superne incisis*, of Linnæus, is very strong, and particularly ungrateful; its taste is warm and aromatic. It abounds with a yellowish gummy resinous juice, very much resembling opoponax. Its virtues are supposed to be similar to those of angelica and master-wort, in expelling flatulencies, exciting sweat, and opening obstructions; therefore it is chiefly used in hysterical disorders and uterine obstructions. The leaves, eaten in salad, are accounted emmenagogue. The root, which is less ungrateful than the leaves, is said to possess similar virtues, and may be employed in powder.

LIGU'STRUM. (From *ligo*, to bind: so named from its use in making bands.)

1. The name of a genus of plants in the Linnæan system. Class, *Diandria;* Order, *Monogynia.*

2. The pharmacopœial name of the herb privet. The *Ligustrum vulgare.*

LI'LALITE. The mineral lipidolite.

LILIACEUS. (From *lilium*, a lily.) Liliaceous, or resembling the lily.

LILIACEÆ. The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of such as have liliaceous corollæ, and a three-lobed stigma; as, colchicum, lilium, crocus, &c.

LILIA'GO. (Diminutive of *lilium*, the lily: so named from the resemblance of its flower to that of a lily.) *Liliastrum.* Spider-wort. The *Anthericum liliastrum* of Linnæus, formerly said to be alexipharmic and carminative.

LI'LIUM. (From λειὸς, smooth, graceful: so named from the beauty of its leaf.) The name of a genus of plants in the Linnæan system. Class, *Hexandria;* Order, *Monogynia.* The lily.

LILIUM ALBUM. The white lily. See *Lilium candidum.*

LILIUM CANDIDUM. The systematic name of the white lily. *Lilium album. Lilium—foliis sparsis, corollis campanulatis, intus glabris,* of

Linnæus. The roots are directed by the Edinburgh pharmacopœia; they are extremely mucilaginous, and chiefly used, boiled in milk and water, in emollient and suppurating cataplasms, to inflammatory tumours. The lily-roots afford a good substitute, in times of scarcity, for bread. The distilled water has been sometimes used as a cosmetic.

Lilium convallium. See *Convallaria majalis.*

Lilium martagon. The martagon lily. Linnæus tells us that the root of this plant forms a part of the ordinary food of the Siberians.

LILY. See *Lilium* and *Nymphæa.*

Lily, May. See *Convallaria majalis.*

Lily, water. See *Nymphæa alba,* and *Nymphæa lutea.*

Lily, white. See *Lilium candidum.*

Lily of the valley. See *Convallaria majalis.*

LIMATU'RA. (From *lima,* a file.) File dust or powder.

Limatura ferri. Steel filings are considered as possessing stimulating and strengthening qualities, and are exhibited in worm cases, ataxia, leucorrhœa, diarrhœa, chlorosis, &c.

LI'MAX. (From *limus,* slime: so named from its sliminess.) *Cochlea terrestris.* The snail. This animal abounds with a viscid slimy juice, which is readily given out by boiling, to milk or water, so as to render them thick and glutinous. These decoctions are apparently very nutritious and demulcent, and are recommended in consumptive cases and emaciations.

LIMBUS. The brim or border. Applied to a part of the corolla in botany. See *Corolla.*

LIME. *Calx.* 1. The oxide of calcium, one of the primitive earths. It is found in great abundance in nature, though never pure, or in an uncombined state. It is always united to an acid, and very frequently to the carbonic acid, as in chalk, common lime-stone, marble, calcareous spar, &c. It is contained in the waters of the ocean; it is found in vegetables; and is the basis of the bones, shells, and other hard parts of animals. Its combination with sulphuric acid is known by the name of sulphate of lime (*gypsum,* or plaster of Paris.) Combined with fluoric acid it constitutes fluate of lime, or Derbyshire spar.

Properties.—Lime is in solid masses, of a white colour, moderately hard, but easily reducible to powder. Its taste is bitter, urinous, and burning. It changes blue cabbage juice to a green. It is unalterable by the heat of our furnaces. It splits and falls into powder in the air, and loses its strong taste. It is augmented in weight and in size by slowly absorbing water and carbonic acid from the atmosphere. Its specific gravity is 2.3. It combines with phosphorus by heat. It unites to sulphur both in the dry and humid way. It absorbs sulphuretted hydrogen gas. It unites with some of the metallic oxides. Its slaking by water is attended with heat, hissing, splitting, and swelling up, while the water is partly consolidated and partly converted into vapour; and the lime is reduced into a very voluminous dry powder, when it has been sprinkled with only a small quantity of water. It is soluble when well prepared in about 450 parts of water. It unites to acids. It renders silex and alumine fusible, and more particularly these two earths together.

Method of obtaining Lime.—Since the carbonic acid may be separated from the native carbonate of lime, this becomes a means of exhibiting the lime in a state of tolerable purity. For this purpose, introduce into a porcelain, or earthen retort, or rather into a tube of green glass, well coated over with lute, and placed across a furnace, some powdered Carara marble, or oyster-shell powder. Adapt to its lower extremity a bent tube of glass, conveyed under a bell. If we then heat the tube, we obtain carbonic acid gas; and lime will be found remaining in the tube, or retort.

The burning of lime in the large way, depends on the disengagement of the carbonic acid by heat; and, as lime is infusible in our furnaces, there would be no danger from too violent a heat, if the native carbonate of lime were perfectly pure; but as this is seldom the case, an extreme degree of heat produces a commencement of vitrification in the mixt stone, and enables it to preserve its solidity, and it no longer retains the qualities of lime, for it is covered with a sort of crust, which prevents the absorption of the water when it is attempted to be slaked. This is called over-burnt lime.

In order to obtain lime in a state of great purity, the following method may be had recourse to:

Take Carara marble, or oyster-shells; reduce them to powder, and dissolve the powder in pure acetic acid; precipitate the solution by carbonate of ammonia. Let the precipitate subside, wash it repeatedly in distilled water, let it dry, and then expose it to a white heat for some hours.

The acetic acid, in this operation, unites to the lime, and forms acetate of lime, disengaging at the same time the carbonic acid, which flies off in the gaseous state: on adding to the acetate of lime carbonate of ammonia, acetate of ammonia, and an artificial carbonate of lime are formed; from the latter the carbonic acid is again expelled, by exposure to heat, and the lime is left behind in a state of perfect purity. See *Calx.*

2. A fruit like a small lemon, the juice of which is a very strong acid, and very much used in the making of punch. Externally, the same acid is applied in the cutaneous affections of warm climates, and also as a remedy against the pains that precede the appearance of yaws. See *Tilia.*

Lime, chloride of. The bleaching salt or bleaching powder, sold under the name of oxymuriate of lime.

LIMESTONE. A genus of minerals which Professor Jameson divides into the four following species:

1. Rhomb-spar. 2. Dolomite. 3. Limestone. 4. Arragonite.

Limestone has twelve sub-species.

1. *Foliated limestone.* Of this there are two kinds, calcareous spar, and foliated granular limestone.

2. *Compact limestone,* of which there are three kinds, common compact limestone, blue Vesuvian, and roestone.

3. *Chalk.*

4. *Agaric mineral,* or *Rock milk.*

5. *Fibrous limestone,* to which belong the satin spar, and the fibrous calc-sinter.

6. *Tufaceous limestone,* or *calc-tuff.*

7. *Pisiform limestone,* or *peastone.*

8. *Slate spar.*

9. *Aphrite.*

10. *Luculite,* of which there are three kinds, compact, prismatic, and foliated.

11. *Marle,* of which there are two species, the earthy and compact.

12. *Bituminous marle slate.*

Limestone, bituminous. See *Bituminous limestone.*

LIME-TREE. See *Tilia.*

Lime-water. See *Calcis liquor.*

LI'MON. (Hebrew.) See *Citrus medica.*

LIMO'NIUM. (From λειμων, a green field; so called from its colour.) This name has been applied to

1. The *Valeriana rubra.*
2. The *Polygonum fagopyrum.*
3. The *Pyrola rotundifolia.*
4. More commonly to the sea-lavender, or *Statice limonium*, of Linnæus, which is said to possess astringent properties.

LIMO'NUM. (From λειμων, a green field: so called from the colour of its unripe fruit.) The lemon-tree. See *Citrus medica.*

LIMOSIS. (From λιμος, hunger.) The name of a genus of diseases in Good's Nosology. Class, *Cœliaca;* Order, *Enterica.* Morbid appetite. It has seven species, viz. *Limosis avens, expers, pica, cardialgia, flatus, emesis, dyspepsia.*

LINACRE, Thomas, was born at Canterbury, about the year 1460. After studying at Oxford, he travelled to Italy, where he acquired a perfect knowledge of the Latin and Greek languages; and afterwards devoted his attention to medicine and natural philosophy, at Rome. On his return, he graduated at Oxford, and gave lectures there on physic, as well as taught the Greek language. His reputation soon became so high, that he was called to court by Henry VII. who not only entrusted him with the education of his children, but also appointed him his physician; which office he likewise enjoyed under his successor Henry VIII. He appears in this monarch's reign to have stood, above all rivalship, at the head of his profession, and evinced his attachment to its interests, as well as to the public good, by founding medical lectures at the two universities, and obtaining the institution, in 1518, of the royal college of physicians in London. The practice of medicine was then occupied by illiterate monks and empirics, who were licensed by the bishops, whence much mischief must have arisen. A corporate body of regularly bred physicians was therefore established, in whom was vested the sole right of examining and admitting persons to practice, as well as of examining apothecaries' shops. Linacre was the first president, which office he retained during the remainder of his life, and at his death, in 1524, bequeathed his house to the college. He had relinquished practice, and entered into holy orders, about five years before, being greatly afflicted with the stone, which was the cause of his dissolution. In his literary character Linacre stands eminently distinguished, having been one of the first to introduce the learning of the ancients into this country. He translated several of the most valuable works of Galen into Latin; and his style is remarkable for its purity and elegance; he had indeed devoted great time to Latin composition, on which he published a large philosophical treatise. His professional skill was universally allowed among his contemporaries, as well as the honour and humanity with which he exercised the medical art; and the celebrated Erasmus has bestowed upon him the highest commendation. He was buried in St. Paul's Cathedral, where a monument was afterwards erected to his memory, with a Latin inscription, by Dr. Caius.

LINAGRO'STIS. (From λινον, cotton, and αγρωϛις, grass: so called from the softness of its texture.) Cotton-grass. The *Eriophorum* of Linnæus, four species of which are found in Britain.

LINANGI'NA. (From *linum*, flax, and *ango*, to strangle: so called, because, if it grows among the flax or hemp, it twists round it, and chokes it.) The herb dodder. The *Cuscuta europœa* of Linnæus.

LINA'RIA. (From *linum*, flax: named from the resemblance of its leaves to those of flax.) See *Antirrhinum linaria.*

LI'NCTUS. (*Linctus, us,* m.; from *lingo*, to lick.) *Lohoc; Eclegma; Elexis; Elegma; Eclectos; Ecleitos; Illinctus.* A loch, a lambative. A term in pharmacy, that is generally applied to a soft and somewhat oily substance, of the consistence of honey, which is licked off the spoon, it being too solid and adhesive to be taken otherwise.

LI'NÆA. (From *linum*, a thread.) This term is applied to some parts which have a thread or line-like appearance, as the long tendinous appearance of the muscles in the abdomen, &c.

Linea alba. *Linea centralis.* An aponeurosis that extends from the scrobiculus cordis straight down to the navel, and from thence to the pubes. It is formed by the tendinous fibres of the internal oblique ascending and the external oblique descending muscles, and the transversalis, interlaced with those of the opposite side.

Lineæ semilunares. The lines which bound the outer margin of the recti muscles, formed by the union of the abdominal tendons.

Lineæ transversæ. The lines which cross the *recti* muscles of the abdomen.

LINEARIS. Linear. Applied to leaves, petals, leaf-stalks, seeds, &c. of plants, which are narrow, with parallel sides, as the leaves of most grasses, those of the *Narcissus, Pseudonarcissus*, and the petals of the *Tussilago farfara*, leaf-stalk of the *Citrus medica*, and seeds of the *Crucianella.*

LINEATUS. Lineate. See *Linearis.*

LI'NGUA. (From *lingo*, to lick up.) The tongue. See *Tongue.*

Lingua avis. The seeds of the *Fraxinus*, or ash, are so called, from their supposed resemblance to a bird's tongue.

Lingua canina. So called from the resemblance of its leaves to a dog's tongue. See *Cynoglossum.*

Lingua cervina. See *Asplenium Scolopendrium.*

LINGUA'LIS. (From *lingua*, the tongue.) *Basio-glossus*, of Cowper. A muscle of the tongue. It arises from the root of the tongue laterally, and runs forward between the hyoglossus and genio-glossus, to be inserted into the tip of the tongue, along with part of the styloglossus. Its use is to contract the substance of the tongue, and to bring it backwards.

LINGUIFORMIS. See *Lingulatus.*

LINGULATUS. (From *lingua*, a tongue.) Tongue-shaped. A term applied to a leaf of a thick, oblong, blunt figure, generally cartilaginous at the edges; as in the *Mesembryanthemum linguiforme.*

LINIMENT. See *Linimentum.*

LINIME'NTUM. (From *lino*, to anoint.) A liniment. An oily substance of a mediate consistence, between on ointment and oil, but so thin as to drop. The following are some of the most approved forms.

Linimentum æruginis. Liniment of verdigris, formerly called oxymel æruginis, mel Ægyptiacum, and unguentum Ægyptiacum:—Take of verdigris, powdered, an ounce; vinegar, seven fluid-ounces; clarified honey, fourteen ounces. Dissolve the verdigris in the vinegar, and strain it through a linen cloth; having added the honey gradually, boil it down to a proper consistence.

Linimentum ammoniæ fortius. Strong liniment of ammonia.—Take of solution of ammonia, a fluid-ounce; olive oil, two fluid-ounces. Shake them together until they unite. A more powerful stimulating application than the former, acting as a rubefacient. In pleurodynia, indolent tumours, stiffness of the joints, and arthritic pains, it is to be preferred to the milder one.

Linimentum ammoniæ subcarbonatis. Liniment of subcarbonate of ammonia, formerly called linimentum ammoniæ and linimentum volatile.—Take of solution of subcarbonate of ammonia, a fluid-ounce: olive oil, three fluid-ounces. Shake them together until they unite. A stimulating liniment, mostly used to relieve rheumatic pains, bruises, and paralytic numbness.

Linimentum aquæ calcis. Liniment of lime-water. Take of lime-water, olive oil, of each eight ounces; rectified spirit of wine, one ounce. Mix. This has been long in use as an application to burns and scalds.

Linimentum camphoræ. Camphor liniment. Take of camphor, half an ounce; olive oil, two fluid-ounces. Dissolve the camphor in the oil. In retentions of urine, rheumatic pains, distentions of the abdomen from ascites, and tension of the skin from abscess, this is an excellent application.

Linimentum camphoræ compositum. Compound camphor liniment. Take of camphor, two ounces; solution of ammonia, six fluid-ounces; spirit of lavender, a pint. Mix the solution of ammonia with the spirit in a glass retort; then, by the heat of a slow fire, distil a pint. Lastly, in this distilled liquor dissolve the camphor. An elegant and useful stimulant application in paralytic, spasmodic, and rheumatic diseases. Also for bruises, sprains, rigidities of the joints, incipient chilblains, &c. &c.

Linimentum hydrargyri. Mercurial liniment. Take of strong mercurial ointment, prepared lard, of each four ounces; camphor, an ounce; rectified spirit, fifteen minims; solution of ammonia, four fluid-ounces. First powder the camphor, with the addition of the spirit, then rub it with the mercurial ointment and the lard; lastly, add gradually the solution of ammonia, and mix the whole together. An excellent formula for all surgical cases, in which the object is to quicken the action of the absorbents, and gently stimulate the surfaces of parts. It is a useful application for diminishing the indurated state of particular muscles, a peculiar affection every now and then met with in practice; and it is peculiarly well calculated for lessening the stiffness and chronic thickening often noticed in the joints. If it be frequently or largely applied, it affects the mouth more rapidly than the mercurial ointment.

Linimentum opiatum. A resolvent anodyne embrocation, adapted to remove indolent tumours of the joints, and those weaknesses which remain after strains and chilblains before they break.

Linimentum saponis compositum. Compound soap liniment. *Linimentum saponis.* Take of hard soap, three ounces; camphor, an ounce; spirit of rosemary, a pint. Dissolve the camphor in the spirit, then add the soap, and macerate in the heat of a sand bath, until it be melted. The basis of this form was first proposed by Riverius, and it is now commonly used under the name of opodeldoc. This is a more pleasant preparation, to rub parts affected with rheumatic pains, swellings of the joints, &c. than any of the foregoing, and at the same time not inferior, except where a rubefacient is required.

Linimentum saponis cum opio. Soap liniment, with opium. Take of compound soap liniment, six ounces; tincture of opium, two ounces. Mix. For dispersing indurations and swellings, attended with pain, but no acute inflammation.

Linimentum terebinthinæ. Turpentine liniment. Take of resin cerate, a pound; oil of turpentine, half a pint. Add the oil of turpentine to the cerate, previously melted, and mix. This liniment is very commonly applied to burns, and was first introduced by Mr. Kentish, of Newcastle.

Linimentum terebinthinæ vitriolicum. Vitriolic liniment of turpentine. Take of olive oil, ten ounces; oil of turpentine, four ounces; vitriolic acid, thee drachms. Mix. This preparation is said to be efficacious in chronic affections of the joints, and in the removal of long existing effects of sprains and bruises.

Liniment of ammonia. See *Linimentum ammoniæ.*

Liniment of camphire. See *Linimentum camphoræ.*

Liniment of mercury. See *Linimentum hydrargyri.*

Liniment of turpentine. See *Linimentum terebinthinæ.*

Liniment of verdigris. See *Linimentum æruginis.*

LINNÆ'A. (So named in honour of Linnæus.) The name of a genus of plants in the Linnæan system. Class, *Didynamia;* Order, *Angiospermia.*

Linnæa borealis. The systematic name of the plant named in honour of the immortal Linnæus, which has a bittter sub-astringent taste, and is used in some places in the form of fomentation, to rheumatic pains, and an infusion with milk is much esteemed in Switzerland in the cure of sciatica.

LINNÆUS, Charles, was born in Sweden, in 1707. He derived at a very early age from his father, that attachment to the study of nature, by which he afterwards so eminently distinguished himself. He was intended for the church, but made so little improvement in the requisite learning, that this was soon abandoned for the profession of medicine. He appears to have had a singular inaptitude for learning languages; though he was sufficiently versed in Latin. His scanty finances much embarrassed his progress at first; but his taste for botany at length having procured him the patronage of Dr. Celsius, professor of divinity at Upsal, he was enabled to pursue his studies to more advantage. In 1730, he was appointed to give lectures in the botanic garden, and began to compose some of those works, by which he rendered his favourite science more philosophical, and more popular than it had ever been before. Two years afterwards he was commissioned to make a tour through Lapland, of which he subsequently published an interesting account; and having learnt the art of assaying metals, he gave lectures on this subject also on his return. In 1735, he took his degree in physic at Harderwyck, and in his inaugural dissertation advanced a strange hypothesis, that intermittent fevers are owing to particles of clay, taken in with the food, obstructing the minute arteries. Soon after this his Systema Naturæ first appeared; which was greatly enlarged and improved in numerous successive editions. In Holland, he fortunately obtained the support of a Mr. Clifford, an opulent banker, whereby he was enabled to visit England also; but his great exertions afterwards impaired his health, and being attacked with a severe intermittent, he could not resist the desire, when somewhat recovered, of returning to his native country. Arriving there in

1738, he settled at Stockholm, where his reputation soon procured him some medical practice, and the appointment of physician to the navy, as well as lecturer on botany and mineralogy; a literary society was also established, of which he was the first president, and by which numerous volumes of transactions have since been published. In 1740, he was chosen professor of medicine at Upsal, having been admitted a member of that academy on his return to Sweden; he also shared with Dr. Rosen the botanical duties, and considerably improved the garden; he was afterwards made secretary, and on some public occasions did the honours of the university. He received likewise marks of distinction from several foreign societies. About the year 1746, he was appointed Archiater; and it became an object of national interest to make additions to his collection from every part of the world. A systematic treatise on the Materia Medica was published by him in 1749; and two years after his Philosophia Botanica, composed during a severe fit of the gout, in which he supposed himself to have derived great benefit from taking a large quantity of wood strawberries. This was soon followed by his great work, the Species Plantarum; after which he was honoured with the order of the Polar Star, never before conferred for literary merit; and having declined a splendid invitation to Spain, he was raised to the rank of nobility. In 1763 his son was allowed to assist him in the botanical duties. About this time he published his Genera Morborum, and three years after his Clavis Medicinæ. His medical lectures, though too theoretical, were very much esteemed; but he had declined general practice on his establishment at Upsal. As he advanced in life, the fatiguing occupations, in which he was engaged, impaired his health, notwithstanding his temperate and regular habits; and at length brought on his dissolution in 1778. This was regarded as a loss to the nation, and even to the world. About ten years after a society, adopting his name, was formed in this country, which has published many valuable volumes of transactions, and the president purchased Linnæus's collections of his widow; similar institutions have also been established in other parts of the world.

Linnæan system. This name is applied particularly to that arrangement of plants, which Linnæus has founded on the fructification or sexes of plants. See *Sexual system of plants.*

LINOSPE'RMUM. (From λινον, flax, and σπερμα, seed.) See *Linum usitatissimum.*

Linozostris. A name given by the ancient Greek writers to two plants, very different from one another. The one is the *Mercurialis*, or British mercury; the other the *Epilinum*, or dodder.

LINSEED. See *Linum usitatissimum.*

LINT. See *Linteum.*

LI'NTEUM. Lint A soft woolly substance, made by scraping old linen cloth, and employed in surgery as the common dressing in all cases of wounds and ulcers, either simply or covered with different unctuous substances.

LI'NUM. (From λειος, soft, smooth: so called from its soft, smooth, texture.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria.* Order, *Pentagynia.*

2. The pharmacopœial name of the common flax. See *Linum usitatissimum.*

Linum catharticum. *Linum minimum; Chamælium.* Purging flax, or mill-mountain. This small plant, *Linum—foliis oppositis ovato-lanceolatis, caule dichotomo, corollis acutis*, of Linnæus, is an effectual and safe cathartic. It has a bitterish and disagreeable taste. A handful infused in half a pint of boiling water is the dose for an adult.

Linum usitatissimum. The systematic name of the common flax. *Linum sylvestre. Linum —calycibus capsulisque mucronatis, petalis crenatis, foliis lanceolatis alternis, caule subsolitario*, of Linnæus. The seeds of this useful plant, called linseed, have an unctuous, mucilaginous, sweetish taste, but no remarkable smell; on expression they yield a large quantity of oil, which, when carefully drawn without the application of heat, has no particular taste or flavour: boiled in water, they yield a large proportion of a strong flavourless mucilage, which is in use as an emollient or demulcent in cough, hoarsenesses, and pleuritic symptoms, that frequently prevail in catarrhal affections; and it is likewise recommended in nephritic pains and stranguries. The meal of the seeds is also much used externally, in emollient and maturating cataplasms. The expressed oil is an officinal preparation, and is supposed to be of a more healing and balsamic nature than the other oils of this class: it has, therefore, been very generally employed in pulmonary complaints, and in colics and constipations of the bowels. The cake which remains after the expression, of the oil, contains the farinaceous part of the seed, and is used in fattening cattle under the name of oil-cake.

Lion-tooth leaf. See *Runcinatus.*

LI'PARIS. (From λιπος, fat: so named from its unctuous quality.) See *Pinguicula.*

LIPAROCE'LE. (From λιπος, fat, and κηλη, a tumour.) That species of sarcocele, in which the substance constituting the disease very much resembles fat.

LIPO'MA. (From λιπος, fat.) A solitary, soft, unequal indolent tumour, arising from a luxuriancy of adeps in the cellular membrane. The adipose structure forming the tumour is sometimes diseased towards its centre, and more fluid than the rest. At other times it does not appear to differ in any respect from adipose membrane, except in the enlargement of the cells containing the fat. These tumours are always many years before they arrive at any size.

LIPOPSY'CHIA. (From λειπω, to leave, and ψυχη, the soul, or life.) A swoon, or fainting. See *Syncope.*

LIPOTHY'MIA. (From λειπω, to leave, and θυμος, the mind.) Fainting. See *Syncope.*

LIPPITU'DO. (From *lippus*, blear-eyed.) *Epiphora; Xerophthalmia.* Blear-eyedness. An exudation of a puriform humour from the margin of the eyelids. The proximate cause is a deposition of acrimony on the glandulæ meibomianæ in the margin of the eye-lids. This humour in the night glues the tarsi of the eye-lids together. The margins of the eye-lids are red and tumefy, are irritated, and excite pain. An opthalmia, fistula lachrymalis, and sometimes an ectropium, are the consequences. The species of the lippitudo are,

1. *Lippitudo infantum*, which is familiar to children, particularly of an acrimonious habit. The lippitudo of infants is mostly accompanied with tinea, or some scabby eruption, which points out that the disease origininates, not from a local, but general or constitutional, affection.

2. *Lippitudo adultorum*, or *senilis.* This arises from various acrimonies, and is likewise common to hard drinkers.

3. *Lippitudo venerea*, which arises from a suppressed gonorrhœa, or fluor albus, and is likewise

observed of children born of parents with venereal complaints.

4. *Lippitudo scrophulosa*, which accompanies other scrophulous symptoms.

5. *Lippitudo scorbutica*, which affects the scorbutic.

LIPY'RIA. (From λειπω, to leave, and πυρ, heat.) A sort of fever, where the heat is drawn to the inward parts, while the external are cold.

LIQUIDA'MBAR. (From *liquidum*, fluid, and *ambar*, a fragrant substance, generally taken for ambergris; alluding to the aromatic liquid gum which distils from this tree.) The name of a genus of plants in the Linnæan system. Class, *Monœcia*; Order, *Polyandria*.

LIQUIDAMBAR STYRACIFLUA. The systematic name of the tree which affords both the liquid amber and *storax liquida*, or liquid storax. The liquid amber is a resinous juice of a yellow colour, inclining to red, at first about the consistence of turpentine, by age hardened into a solid brittle mass. It is obtained by wounding the bark of this tree, which is described by Linnæus the *Liquidambar—foliis palmato-angulatis; foliis indivisis, acutis*. The juice has a moderately pungent, warm, balsamic taste, and a very fragrant smell, not unlike that of the *Styrax calamita* heightened by a little ambergris. It is seldom used medicinally. The *Styrax liquida* is also obtained from this plant by boiling. There are two sorts distinguished by authors; the one the purer part of the resinous matter, that rises to the surface in boiling, separated by a strainer of the consistence of honey, tenacious like turpentine, of a reddish or ash-brown colour, moderately transparent, of an acrid unctuous taste and a fragrant smell, faintly resembling that of the solid styrax, but somewhat disagreeable. The other, the more impure part which remains on the strainer, untransparent, and in smell and taste much weaker than the former. Their use is chiefly as stomachics, in the form of plaster.

LIQUIFACTION. A chemical term, in some instances synonymous with *fusion*, in others with the word deliquescence, and in others with the word *solution*.

LIQUIRI'TIA. (From *liquor*, juice, or from *elikoris*, Welsh.) See *Glycyrrhiza*.

LI'QUOR. A liquor. This term is applied in the last editions of the London Pharmacopœia to some preparations, before improperly called waters; as the *aqua ammoniæ*, &c.

LIQUOR ACETATIS PLUMBI. See *Plumbi acetatis liquor*.

LIQUOR ACETATIS PLUMBI DILUTIS. See *Plumbi acetatis liquor dilutus*.

LIQUOR ÆTHEREUS VITRIOLICUS. See *Æther sulphuricus*.

LIQUOR ALUMINIS COMPOSITUS. Compound solution of alum. Take of alum sulphate of zinc, of each half an ounce; boiling water two pints. Dissolve at the same time the alum and sulphate of zinc in the water, and then strain the solution through paper. This water was long known in our shops under the title of *aqua aluminosa Bateana*. It is used for cleansing and healing ulcers and wounds, and for removing cutaneous eruptions, the part being bathed with it hot three or four times a-day. It is sometimes likewise employed as a collyrium; and as an injection in fluor albus and gonorrhœa, when not accompanied with virulence.

LIQUOR AMMONIÆ. See *Ammonia*.

LIQUOR AMMONIÆ ACETATIS. See *Ammoniæ acetatis liquor*.

LIQUOR AMMONIÆ CARBONATIS. See *Ammoniæ subcarbonatis liquor*.

LIQUOR AMMONIÆ SUBCARBONATIS. See *Ammoniæ subcarbonatis liquor*.

Liquor of Ammonia. See *Ammonia*.

LIQUOR AMNII. All that fluid which is contained in the membranaceous ovum surrounding the fœtus in utero is called by the genera name of the waters, the water of the amnion, or ovum, or liquor amnii. The quantity, in proportion to the size of the different parts of the ovum, is greatest by far in early pregnancy. At the time of parturition, in some cases, it amounts to or exceeds four pints; and, in others, it is scarcely equal to as many ounces. It is usually in the largest quantity when the child has been some time dead, or is born in a weakly state. This fluid is generally transparent, often milky, and sometimes of a yellow, or light brown colour, and very different in consistence; and these alterations seem to depend upon the state of the constitution of the parent. It does not coagulate with heat, like the serum of the blood; and, chemically examined, it is found to be composed of phlegm, earthy matter, and sea-salt, in different proportions in different subjects, by which the varieties in its appearance and consistence are produced. It has been supposed to be excrementitious: but it is generally thought to be secreted from the internal surface of the ovum, and to be circulatory as in other cavities. It was formerly imagined that the fœtus was nourished by this fluid, of which it was said to swallow some part frequently; and it was then asserted, that the qualities of the fluid were adapted for its nourishment. But there have been many examples of children born without any passage to the stomach; and a few of children in which the head was wanting, and which have nevertheless arrived at the full size. These cases fully prove that this opinion is not just, and that there must be some other medium by which the child is nourished, besides the waters. The incontrovertible uses of this fluid are, to serve the purpose of affording a soft bed for the residence of the fœtus, to which it allows free motion, and prevents any external injury during pregnancy: and inclosed in the membranes, it procures the most gentle, yet efficacious, dilatation of the os uteri, and soft parts, at the time of parturition. Instances have been recorded, in which the waters of the ovum are said to have been voided so early as in the sixth month of pregnancy, without prejudice either to the child or parent. The truth of these reports seems to be doubtful, because when the membranes are intentionally broken, the action of the uterus never fails to come on, when all the water is evacuated. A few cases have occurred to me, says Dr. Denman, in practice, which might have been construed to be of this kind; for there was a daily discharge of some colourless fluid from the vagina, for several months before delivery; but there being no diminution of the size of the abdomen, and the waters being regularly discharged at the time of labour, it was judged that some lymphatic vessels near the os uteri had been ruptured, and did not close again till the patient was delivered. He also met with one case, in which, after the expulsion of the placenta, there was no sanguineous discharge, but a profusion of lymph, to the quantity of several pints, in a few hours after delivery; but the patient suffered no inconvenience except from surprise.

LIQUOR ANTIMONII TARTARIZATI. See *Antimonii tartarizati liquor*.

LIQUOR ARSENICALIS. See *Arsenicalis liquor*.

LIQUOR CALCIS. See *Calcis liquor*.

LIQUOR CUPRI AMMONIATI. See *Cupri ammoniati liquor*.

LIQUOR FERRI ALKALINI. See *Ferri alkalini liquor.*

LIQUOR HYDRARGYRI OXYMURIATIS. See *Hydrargyri oxymurias.*

LIQUOR MINERALIS ANODYNUS HOFFMANNI. Hoffmann's anodyne liquor. See *Spiritus ætheris sulphurici compositi.*

LIQUOR POTASSÆ. See *Potassæ liquor.*

LIQUOR SUBCARBONATIS POTASSÆ. See *Potassæ subcarbonatis liquor.*

LIQUOR VOLATILIS CORNU CERVI. This preparation of the fluid volatile alkali, commonly termed hartshorn, is in common use to smell at in faintings, &c. See *Ammoniæ subcarbonas.*

LIQUORICE. See *Glycyrrhiza.*

Liquorice, Spanish. See *Glycyrrhiza.*

LIRELLA. (A diminutive of *lire*, a ridge between two furrows.) Acharius' name for the black letter-like receptacles of the genus *Opegrapha.*

LISTER, MARTIN, was born about 1638, of a Yorkshire family, settled in Buckinghamshire, which produced many medical practitioners of reputation; and his uncle, Sir Matthew Lister, was physician to Charles I. and president of the college. After studying at Cambridge, where he was made fellow of St. John's college, by royal mandate, he travelled to the Continent for improvement. On his return, in 1670, he settled at York, where he practised for many years with considerable success. Having communicated many papers on the natural history and antiquities of the north of England to the Royal Society, he was elected a fellow of that body; and he likewise enriched the Ashmolean Museum at Oxford. He came, by the solicitation of his friends, to London in 1684, having received a diploma at Oxford; and soon after was admitted a fellow of the College of Physicians. In 1698 he accompanied the embassy to France, and published an account of this journey on his return. He was made physician to Queen Anne about three years before his death, which happened in the beginning of 1712. He wrote on the English medicinal waters, on small-pox, and some other diseases; but his writings, though containing some valuable practical observations, are marked by too much hypothesis and attachment to ancient doctrines; and he particularly condemned the cooling plan of treatment in febrile diseases, introduced by the sagacious Sydenham. His reputation is principally founded on his researches in natural history and comparative anatomy, on which he published several separate works, as well as nearly forty papers in the Philosophical Transactions.

LITHAGO'GA. (From λιθος, a stone, and αγω, to bring away.) Medicines which expel the stone.

LITHARGE. See *Lithargyrus.*

Litharge plaster. See *Emplastrum lithargyri.*

LITHA'RGYRUS. (From λιθος, a stone, and αργυρος, silver.) *Lithargyrum.* Litharge. An oxide of lead, in an imperfect state of vitrification. When silver is refined by cupellation with lead, this latter metal, which is scorified, and causes the scorification of the imperfect metals alloyed with the silver, is transformed into a matter composed of small semitransparent shining plates, resembling mica; which is litharge. Litharge is more or less white or red, according to the metals with which the silver is alloyed. The white is called litharge of silver; and the red has been improperly called litharge of gold. See *Lead,* and *Plumbi subacetatis liquor.*

LITHIA. (*Lithia,* from λιθειος, *lapideus.*) *Lithion; Lithina.* 1. A new alkali. It was discovered by Arfredson, a young chemist of great merit, employed in the labaratory of Berzelius. It was found in a mineral from the mine of Uten in Sweden, called *petalite* by D'Andrada, who first distinguished it Sir H. Davy demonstrated by voltaic electricity, that the basis of this alkali is a metal, to which the name of *lithium* has been given.

Berzelius gives the following simple process as a test for lithia in minerals:—

A fragment of the mineral, the size of a pin's head, is to be heated with a small excess of soda. on a piece of platinum foil, by a blowpipe for a couple of minutes. The stone is decomposed, the soda liberates the lithia, and the excess of alkali preserving the whole fluid at this temperature, it spreads over the foil, and surrounds the decomposed mineral. That part of the platinum near to the fused alkali becomes of a dark colour, which is more intense, and spreads over a larger surface, in proportion as there is more lithia in the mineral. The oxidation of the platinum does not take place beneath the alkali, but only around it, where the metal is in contact with both air and lithia. Potassa destroys the reaction of the platinum on the lithia, if the lithia be not redundant. The platina resumes its metallic surface, after having been washed and heated.

Caustic lithia has a very sharp burning taste. It destroys the cuticle of the tongue like potassa. It does not dissolve with great facility in water, and appears not to be much more soluble in hot than in cold water. In this respect it has an analogy with lime. Heat is evolved during its solution in water.

When exposed to the air it does not attract moisture, but absorbs carbonic acid, and becomes opaque. When exposed for an hour to a white heat in a covered platinum crucible, its bulk does not appear to be diminished: but it has absorbed a quantity of carbonic acid.

2. The name of a genus of diseases in Good's Nosology. Class, *Eccritica;* Order, *Catotica.* Urinary calculus.

LI'THIAS. A lithiate or salt, formed by the union of the lithic acid, or acid of the stone sometimes found in the bladder of animals with salifiable bases; thus *lithiate of ammonia,* &c.

LITHI'ASIS. (From λιθος, a stone.)

1. The formation of stone, or gravel.

2. A tumour of the eyelid, under which is a hard concretion, resembling a stone.

LITHIC ACID. (*Acidum lithicum;* from λιθος, a stone, because it is obtained from the stones of the bladder.) *Acidum uricum.* This was discovered in analysing human calculi, of many of which it constitutes the greater part, and of some, particularly that which resembles wood in appearance, it forms almost the whole. It is likewise present in human urine, and in that of the camel. It is found in those arthritic concretions commonly called chalkstones. It is often called *uric* acid.

The following are the results of Scheele's experiments on calculi, which were found to consist almost wholly of this acid.

1. Dilute sulphuric acid produced no effect on the calculus, but the concentrated dissolved it; and the solution, distilled to dryness, left a black coal, giving off sulphurous acid fumes. 2. The muriatic acid, either diluted or concentrated, had no effect on it even with ebullition. 3. Dilute nitric acid attacked it cold; and with the assistance of heat produced an effervescence and red vapour, carbonic acid was evolved, and the calculus was entirely dissolved. The solution was acid, even when saturated with the calculus, and

gave a beautiful red colour to the skin in half an hour after it was applied; when evaporated, it became of a blood-red, but the colour was destroyed by adding a drop of acid: it did not precipitate muriate of barytes, or metallic solutions, even with the addition of an alkali; alkalies rendered it more yellow, and if superabundant, changed it by a strong digested heat to a rose colour; and this mixture imparts a similar colour to the skin, and is capable of precipitating sulphate of iron black, sulphate of copper green, nitrate of silver grey, superoxygenated muriate of mercury, and solutions of lead and zinc, white. Lime water produced in the nitric solution a white precipitate, which dissolved in the nitric and muriatic acids without effervescence, and without destroying their acidity. Oxalic acid did not precipitate it. 4. Carbonate of potassa did not dissolve it, either cold or hot, but a solution of perfectly pure potassa dissolved it even cold. The solution was yellow; sweetish to the taste; precipitated by all the acids, even the carbonic; did not render lime water turbid; decomposed and precipitated solution of iron brown, of copper grey, of silver black, of zinc, mercury, and lead, white; and exhaled a smell of ammonia. 5. About 200 parts of lime water dissolved the calculus by digestion, and lost its acrid taste. The solution was partly precipitated by acids. 6. Pure water dissolved it entirely, but it was necessary to boil for some time 360 parts with one of the calculus in powder. This solution reddened tincture of litmus, did not render lime water turbid, and on cooling deposited in small crystals almost the whole of what it had taken up. 7. Seventy-two grains distilled in a small glass retort over an open fire, and gradually brought to a red heat, produced water of ammonia mixed with a little animal oil, and a brown sublimate, weighing 28 grains, and 12 grains of coal remained, which preserved its black colour on red-hot iron in the open air. The brown sublimate was rendered white by a second sublimation; was destitute of smell, even when moistened by an alkali; was acid to the taste; dissolved in boiling water, and also in alcohol, but in less quantity; did not precipitate lime water; and appeared to resemble succinic acid.

Fourcroy has found, that this acid is almost entirely soluble in 2000 times its weight of cold water, when the powder is repeatedly treated with it. From his experiments he infers, that it contains azote, with a considerable portion of carbon, and but little hydrogen, and little oxygen.

Of its combinations with the basis we know but little.

Much additional information has been obtained within these few years on the nature and habitudes of the lithic acid. Dr. Henry wrote a medical thesis, and afterwards published a paper on the subject, in the second volume of the new series of the Manchester memoirs, both of which contain many important facts. He procured the acid in the manner above described by Fourcroy. It has the form of white shining plates, which are denser than water. Has no taste nor smell. It dissolves in about 1400 parts of boiling water. It reddens the infusion of litmus. When dissolved in nitric acid, and evaporated to dryness, it leaves a pink sediment. The dry acid is not acted on nor dissolved by the alkaline carbonates, or sub-carbonates. It decomposes soap when assisted by heat; as it does also the alkaline sulphurets and hydrosulphurets. No acid acts on it, except those that occasion its decomposition. It dissolves in hot solutions of potassa and soda, and likewise in ammonia, but less readily. The lithates may be formed, either by mutually saturating the two constituents, or we may dissolve the acid in an excess of base, and we may then precipitate by carbonate of ammonia. The lithates are all tasteless, and resemble in appearance lithic acid itself. They are not altered by exposure to the atmosphere. They are very sparingly soluble in water. They are decomposed by a red heat, which destroys the acid. The lithic acid is precipitated from these salts by all the acids, except the prussic and corbonic. They are decomposed by the nitrates, muriates, and acetates of barytes, strontites, lime, magnesia, and alumina. They are precipitated by all the metallic solutions except that of gold. When lithic acid is exposed to heat, the products are carburetted hydrogen, and carbonic acid, prussic acid, carbonate of ammonia, a sublimate, consisting of ammonia combined with a peculiar acid, which has the following properties:—

Its colour is yellow, and it has a cooling bitter taste. It dissolves readily in water, and in alkaline solutions, from which it is not precipitated by acids. It dissolves also sparingly in alkohol. It is volatile, and when sublimed a second time, becomes much whiter. The watery solution reddens vegetable blues, but a very small quantity of ammonia destroys this property. It does not cause effervescence with alkaline carbonates. By evaporation it yields permanent crystals, but ill defined, from adhering animal matter. These redden vegetable blues. Potassa, when added to these crystals, disengages ammonia. When dissolved in nitric acid, they do not leave a red stain, as happens with uric acid; nor does their solution in water decompose the earthy salts, as happens with alkaline lithates (or urates.) Neither has it any action on the salts of copper, iron, gold, platinum, tin, or mercury. With nitrates of silver, and mercury, and acetate of lead, it forms a white precipitate, soluble in an excess of nitric acid. Muriatic acid occasions no precipitate in the solution of these crystals in water. These properties show, that the acid of the sublimate is different from the uric, and from every other known acid. Dr. Austin found, that by repeated distillations lithic acid was resolved into ammonia, nitrogen, and prussic acid.

When lithic acid is projected into a flask with chlorine, there is formed, in a little time, muriate of ammonia, oxalate of ammonia, carbonic acid, muriatic acid, and malic acid; the same results are obtained by passing chlorine through water, holding this acid in suspension.

LITHIUM. The metallic basis of lithia. See *Lithia.*

LITHOIDES. (From λιθος, a stone, and ειδος, a likeness: so called from its hardness.) The petrous portion of the temporal bone.

LITHO'LABUM. (From λιθος, a stone, and λαμβανω, to seize.) An instrument for extracting the stone from the bladder.

LITHO'LOGY. *Lithologia;* from λιθος, a stone, and λογος, a discourse.) A discourse or treatise on stones.

LITHOMA'RGA. See *Lithomarge.*

LITHOMARGE. Stone-marrow. A mineral of which there are two kinds, the friable and the indurated.

LITHONTRIPTIC. (*Lithontripticus;* from λιθος, a stone, and τριβω, to bear away.) Lithontryptic. From the strict sense and common acceptation of the word, this class of medicine should comprehend such as possess a power of dissolving calculi in the urinary passages. It is, however, doubted by many, whether there be in nature any such substances. By this term, then, is meant those substances which possess a power of removing a disposition in the body to the formation of calculi. The researches of modern chemists have proved, that these calculi consist mostly of a peculiar acid, named the lithic or uric acid. With this substance, the alkalies are capable of uniting and forming a soluble compound; and these are accordingly almost the sole lithontriptics. From the exhibition of alkaline remedies, the symptoms arising from stone in the bladder are very generally alleviated; and they can be given to such an extent that the urine becomes very sensibly alkaline, and is even capable of exerting a solvent power on these concretions. Their administration, however, cannot be continued to this extent for any length of time, from the irritation they produce on the stomach and urinary organs. The use, therefore, of the alkalies, as solvents, or lithontriptics, is now scarcely ever attempted; they are employed merely to prevent the increase of the concretion, and to palliate the painful symptoms, which they do apparently by preventing the generation of lithic acid, or the separation of it by the kidneys; the urine is thus rendered less irritating, and the surface of the calculus is allowed to become smooth.

When the alkalies are employed with this view, they are generally given neutralised, or with excess of carbonic acid. This renders them much less irritating. It at the same time, indeed, diminishes their solvent power; for the alkaline carbonates exert no action on urinary calculi; but they are still capable of correcting that acidity in the primæ viæ, which is the cause of the deposition of the lithic acid from the urine, and therefore serve equally to palliate the disease. And when their acrimony is thus diminished, their use can be continued for any length of time.

It appears from the experiments of Fourcroy, and others, that some other ingredients of calculi, as well as the lithic acid, are dissolved by the caustic alkali, and various experiments have shown that most calculi yield to its power. It is obvious, however, that what is taken by the mouth is subject to many changes in the alimentary canal, and also the lymphatic and vascular systems; and in this way it must be exceedingly difficult to get such substances (even were they not liable to alterations) in sufficient quantity into the bladder. Indeed, there are very few authenticated cases of the urine being so changed as to become a menstruum for the stone. Excepting the case of Dr. Newcombe, recorded by Dr. Whytt, the instance of Mr. Home is almost the only one. Though lithontriptics, however, may not in general dissolve the stone in the bladder, yet it is an incontrovertible fact that they frequently mitigate the pain; and, to lessen such torture as that of the stone in the bladder, is surely an object of no little importance. Lime was long ago known as a remedy for urinary calculi, and different methods were employed to administer it. One of these plans fell into the hands of a Mrs. Steevens, and her success caused great anxiety for the discovery of the secret. At last Parliament bought the secret for the sum of 5000*l.* In many instances, stones which had been unquestionably felt were no longer to be discovered; and as the same persons were examined by surgeons of the greatest skill and eminence, both before and after the exhibition of her medicines, it was no wonder that the conclusion was drawn that the stones really were dissolved. From the cessation of such success, and from its now being known that the stones are occasionally protruded between the fasciculi of the muscular fibres of the bladder, so as to be lodged in a kind of cyst on the outside of the muscular coat, and cause no longer any grievances, surgeons of the present day are inclined to suspect that this must have happened in Mrs. Steevens' cases. This was certainly what happened in one of the cases on whom the medicine had been tried. It is evident that a stone so situated would not any longer produce irritation, but would also be quite indiscoverable by the sound, for, in fact, it is no longer in the cavity of the bladder.

As soap was, with reason, supposed to increase the virtues of the lime, it led to the use of caustic alkali, taken in mucilage, or veal broth. Take of pure potassa ℥viij; of quick lime ℥iv; of distilled water, ℔ij. Mix them well together in a large bottle, and let them stand for twenty-four hours. Then pour off the ley, filter it through paper, and keep it in well-stopped vials for use. Of this, the dose is from thirty drops to ʒij, which is to be repeated two or three times a day, in a pint of veal broth, early in the morning, at noon, and in the evening. Continue this plan for three or four months, living, during the course, on such things as least counteract the effect of the medicine.

The common fixed alkalies, or carbonated alkali, and the acidulous soda-water, have of late been used as lithontriptics. Honey has also been given; and Mr. Home, surgeon at the Savoy, has recorded its utility in his own and in his father's cases. Bitters have likewise been tried.

Dismissing all theories, lime water, soap, acidulous soda-water, caustic alkali, and bitters, are useful in cases of stone. Of the soap, as much may be taken as the stomach will bear, or as much as will prove gently laxative; but of the lime-water, few can take more than a pint daily.

The acidulous soda-water may be taken in larger quantities, as it is more agreeable.

There is a remedy celebrated in Holland, under the name of liquor lithontriptica Loosii, which contains, according to an accurate analysis, muriate of lime. This professor Hufeland recommends in the following form:

℞ Calcis muriate ʒj.
Aquæ distillatæ, ℥ij. ft. solutio.

Thirty drops are to be taken four times a day, which may be increased as far as the stomach will bear.

For curing stone patients, little reliance can be placed in any lithontriptics hitherto discovered, though they may rationally be given, with a confident hope of procuring an alleviation of the fits of pain attending the presence of stone in the bladder. After all, the only certain method of getting rid of the calculus is the operation. See *Lithotomy.*

LITHONTRY'PTIC. (From λιθος, a stone, and ϑρυπτω, to break.) See *Lithontriptic.*

LITHOSPE'RMUM. (From λιθος, a stone, and σπερμα, seed; named from the hardness of its seed.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia.*

2. The pharmacopœial name of common gromwell. See *Lithospermum officinale.*

LITHOSPERMUM OFFICINALE. The systematic name of the officinal gromwell. The seeds of this officinal plant, *Lithospermum—seminibus lævibus, corollis vix calycem superantibus, foliis lanceolatis*, of Linnæus, were formerly supposed, from their stony hardness, to be efficacious in calculous and gravelly disorders. Little credit is given to their lithontriptic character, yet they are occasionally used as diuretic for clearing the urinary passages, and for obviating strangury, in the form of emulsion.

LITHO'TOMY. (*Lithotomia;* from λιθος, a stone, and τεμνω, to cut.) *Cystomia.* The operation of cutting into the bladder, in order to extract a stone. Several methods have been recommended for performing this operation, but there are only two which can be practised with any propriety. One is, where the operation is to be performed immediately above the pubes, in that part of the bladder which is not covered with peritonæum, called the *high operation.* The other, where it is done in the perinæum, by laying open the neck and lateral part of the bladder, so as to allow of the extraction of the stone, called the *lateral operation,* from the prostate gland of the neck of the bladder being laterally cut.

LITMUS. The beautiful blue prepared from a white lichen. See *Lichen roccella.*

Li'tron. See *Nitre.*

Li'tus. A liniment.

LI'VER. (*Hepar,* ἡπαρ.) A large viscus, of a deep red colour, of great size and weight, situated under the diaphragm, in the right hypochondrium, its smaller portion occupying part of the epigastric region. In the human body, the liver is divided into two principal lobes, the right of which is by far the largest. They are divided on the upper side by a broad ligament, and on the other side by a considerable depression or fossa. Between and below these two lobes is a smaller lobe, called *lobulus Spigelii.* In describing this viscus, it is necessary to attend to seven principal circumstances:—its ligaments; its surfaces; its margins; its tubercles; its fissure; its sinus; and the pori biliari.

The *ligaments* of the liver are five in number, all arising from the peritonæum. 1. *The right lateral ligament,* which connects the thick right lobe with the posterior part of the diaphragm. 2. *The left lateral ligament,* which connects the convex surface and margin of the left lobe with the diaphragm, and, in those of whom the liver is very large, with the œsophagus and spleen. 3. *The broad or middle suspensory ligament,* which passes from the diaphragm into the convex surface, and separates the right lobe of the liver from the left. It descends from above through the large fissure to the concave surface, and is then distributed over the whole liver. 4. *The round ligament,* which in adults consists of the umbilical vein, indurated into a ligament. 5. *The coronary ligament.*

The liver has two *surfaces,* one superior, which is convex and smooth, and one inferior, which is concave, and has holes and depressions to receive, not only the contiguous viscera, but the vessels running into the liver.

The *margins* of the liver are also two in number; the one, which is posterior and superior is obtuse, the other, situated anteriorly and inferiorly, is acute.

The *tubercles* of the liver are likewise two in number, viz. *lobulus anonymus,* and *lobulus caudatus,* and are found near the vena portæ.

Upon looking on the concave surface of this viscus, a considerable fissure is obvious, known by the name of the *fissure of the liver.*

In order to expose the *sinus,* it is necessary to remove the gall-bladder, when a considerable sinus, before occupied by the gall-bladder, will be apparent.

The *blood-vessels* of the liver are the hepatic artery, the vena portæ, and the vena cavæ hepaticæ, which are described under their proper names. The *absorbents* of the liver are very numerous. The liver has *nerves,* from the great intercostal and eighth pair, which arise from the hepatic plexus, and proceed along with the hepatic artery and vena portæ into the substance of the liver. With regard to the substance of the liver, various opinions have been entertained. It is, however, now pretty well ascertained to be a large gland, composed of lesser glands connected together by cellular structure. The small glands which thus compose the substance of the liver, are termed penicilli, from the arrangement of the minute ramifications of the vena portæ composing each gland, resembling that of the hairs of a pencil. The chief use of this large viscus is to supply a fluid, named bile, to the intestines, which is of the utmost importance in chylification. The small penicilli perform this function by a specific action on the blood they contain, by which they secrete in their very minute ends the fluid termed *hepatic bile;* but whether they pour it into what is called a follicle, or not, is yet undecided, and is the cause of the difference of opinion respecting the substance of the liver. If it be secreted into a follicle, the substance is truly glandular, according to the notion of the older anatomists: but if it be secreted merely into a small vessel, called a biliary pore (the existence of which can be demonstrated) corresponding to the end of each of the penicilli, without any intervening follicle, its substance is then, in their opinion vascular. According to our notions in the present day, in either case, the liver is said to be glandular; for we have the idea of a gland when any arrangement of vessels performs the office of separating from the blood a fluid or substance different in its nature from the blood. The small vessels which receive the bile secreted by the penicilli, are called *pori biliarii;* these converge together throughout the substance of the liver towards its under surface, and, at length, form one trunk, called *ductus hepaticus,* which conveys the bile into either the *ductus communis choledochus,* or *ductus cysticus.* See *Gall-bladder.*

Liver, inflammation of. See *Hepatitis.*

Liver of sulphur. See *Potassæ sulphuretum.*

LIVER-WORT. See *Marchantia polymorpha.*

Liver-wort, ash-coloured. See *Lichen caninus.*

Liver-wort, ground. See *Lichen caninus.*

Liver-wort, Iceland. See *Lichen islandicus.*

Liver-wort, noble. See *Marchantia polymorpha.*

LI'VOR. (From *liveo,* to be black and blue.) Lividness. A black mark, from a blow. A dark circle under the eye.

LIX. (From λις, light.) Wood-ash.

LIX'IVIAL. Salts are so called which are extracted by lixiviation.

LIXIVIATION. (*Lixivialis;* from *lix,* wood-ash.) *Lessive.* The process employed by chemists of dissolving, by means of warm water, the saline and soluble particles of cinders, the residues of distillation and combustion, coals and natural earths. Salts thus obtained are called *Lixivial salts.*

LIXI'VIUM. (From *lix,* wood-ash.) The liquor in which saline and soluble particles of the residues of distillation and combustion are dissolved.

Lixivium saponarium. See *Potassæ liquor.*

Lixivium tartari. See *Potassæ subcarbonatis liquor.*

LOBATUS. (From *lobus,* a lobe.) Lobed. Applied to leaves which have the margins of the segments lobed, as in *Anemone hepatica,* and to such as are lobed like the vine thistle, and many geraniums.

LOBB, Theophilus, practised as a physician in London with considerable reputation, and left several works on medical topics. He died in 1763, in the 85th year of his age. He wrote on fevers, small-pox, and some other diseases; but his most celebrated publication was, "A Treatise on Solvents of the Stone, and on curing the Stone and the Gout by Aliments," which passed through several editions, and was translated into Latin and French; he considered the morbid matter of an alkaline nature, and vegetable acids as the remedy. He was author also of "A Compendium of the Practice of Physic," and of several papers in the Gentleman's Magazine.

Lobed leaf. See *Lobatus.*

LOBE'LIA. (Named in honour of Lobel, a botanist.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Monogamia.*

2. The pharmacopœial name of the blue lobelia. See *Lobelia syphilitica.*

Lobelia syphilitica. The systematic name of the blue lobelia of the pharmacopœias. The root is the part directed by the Edinburgh Pharmacopœia for medicinal use; in taste it resembles tobacco, and is apt to excite vomiting. It derived the name of *syphilitica* from its efficacy in the cure of syphilis, as experienced by the North American Indians, who considered it as a specific in that disease, and with whom it was long an important secret, which was purchased by Sir William Johnson, and since published by different authors. The method of employing this medicine is stated as follows: a decoction is made of a handful of the roots in three measures of water. Of this half a measure is taken in the morning fasting, and repeated in the evening; and the dose is gradually increased, till its purgative effects become too violent, when the decoction is to be intermitted for a day or two, and then renewed, until a perfect cure is effected. During the use of this medicine, a proper regimen is to be enjoined, and the ulcers are also to be frequently washed with the decoction, or if deep and foul, to be sprinkled with the powder of the inner bark of the New Jersey tea-tree. *Ceanothus americanus.* Although the plant thus used is said to cure the disease in a very short time, yet it is not found that the antisyphilitic powers of the lobelia have been confirmed in any instance of European practice.

LO'BULUS. (Dim. of *lobus,* a lobe.) A small lobe, as *lobulus spigelii.*

Lobulus accessorius. See *Lobulus anonymus.*

Lobulus anonymus. *Lobulus accessorius anterior-quadratus.* The anterior point of the right lobe of the liver. Others define it to be that space of the great lobe betwixt the fossa of the umbilical vein and gall-bladder, and extending forward from the fossa for the lodgment of the vena portæ, to the anterior margin of the liver.

Lobulus caudatus. *Processus caudatus.* A tail-like process of the liver, stretching downward from the middle of the great right lobe to the lobulus spigelii. It is behind the gall-bladder and betwixt the fossa venæ portarum, and the fissure for the lodgment of the vena cava.

Lobulus spigelii. *Lobulus posterior; Lobulus posticus papillatus.* A lobe of the liver betwixt the two greater lobes, but rather belonging to the right great lobe. From its situation deep behind, and from its having a perpendicular papilla-like projection, it is called lobulus posterior, or papillatus. To the left side it has the fissure for the lodgment of the ductus venosus; on the right, the fissure for the vena cava; and above, it has the great transverse fissure of the liver, for the lodgment of the cylinder of the porta; obliquely to the right, and upwards, it has a connection with the lower concave surface of the great lobe, by the processus caudatus, which Winslow calls one of the roots of the lobulus spigelii. It is received into the bosom of the lesser curve of the stomach.

LOCA'LES. (*Locales,* the plural of *lochalis.*) The fourth class of Cullen's Nosology, which comprehends morbid affections that are partial, and includes eight orders, viz. dysæsthesiæ, dysorexiæ, dyscinesiæ, apocenoses, epischeses, tumores, ectopia, and dialyses.

LOCA'LIS. Local. Belonging to a part and not the whole. A common division of diseases is into general and local.

Localis membrana. The pia mater.

LO'CHIA. (From λοχευω, to bring forth.) The cleansings. The serous, and for the most part green-coloured, discharge that takes place from the uterus and vagina of women, during the first four days after delivery.

LOCHIORRHŒ'A. (From λοχια, and ρεω, to flow.) An excessive discharge of the lochia.

LOCKED-JAW. See *Tetanus.*

LOCULAMENTUM. In botany means the space or cell between the valves and partitions of a capsule; distinguished from their number into unilocular, bilocular, &c. See *Capsula.*

LOCUSTA. A term sometimes applied to the spikelet of grasses. See *Spicula.*

LOGWOOD. See *Hæmatoxylon campechianum.*

LOMENTACEÆ. (From *lomentum;* in allusion to the pulse-like nature of the plants in question, so as to keep in view their analogy with the *papilionaceæ.*) The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of such as have a bivalve pericarpium or legume, and not papilionaceous corolls; as Cassia, Fumaria, Ceretonia, &c.

LOMENTUM. 1. A word used by old writers on medicine, to express a meal made of beans, or bread made of this meal, and used as a wash.

2. A bivalve pericarpium, divided into cells by very small partitions, never lateral like those of the legume.

From its figure it is termed,

1. *Articulatum,* when the partitions are visible externally; as in Hedysarum argenteum.

2. *Moniliforme,* necklace-like, consisting of a number of little globules; as in Hedysarum moliferum.

3. *Aculeatum;* as in Hedysarum onobrychis.

4. *Crystatum;* as in Hedysarum caput galli.

5. *Isthmis interceptum,* when the cells are much narrower than the joints; as in Hippocrepis.

6. *Corticosum,* the external bark being woody, and the inside pulpy; as in Cassia fistula.

LOMMIUS, Jodocus, was born in Guelderland, about the commencement of the 16th century. Having received from his father a good classical education, he turned his attention to medicine, which he studied chiefly at Paris. He practised for a considerable time at Tournay, where he was pensionary-physician in 1557; and three years after he removed to Brussels. The period of his death is not known. He left three small works, which are still valued from the purity and elegance of their Latinity; a Commentary on Celsus; Medicinal Observations in Three Books; and a Treatise on the Cure of continued

Fevers; the two latter have been several times reprinted and translated.

LOMONITE. Diphrismatic zeolite.

LONCHI'TIS. (From λογχη, a lance; so named because the leaves resemble the head of a lance.) The herb spleenwort. The Ceterach officinalis.

Longa'num. (From *longus*, long; so named from its length.) The intestinum rectum.

LONGING. A desire peculiar to the female, and only during pregnancy, and those states in which the uterine discharge is suppressed.

LONGISSIMUS. The longest. Parts are so named from their length, compared to that of others; as *longissimus dorsi*, &c.

Longissimus dorsi. *Lumbo dorso trachelien*, of Dumas. This muscle, which is somewhat thicker than the sacrolumbalis, greatly resembles it, however, in its shape and extent, and arises in common with that muscle, between it and the spine. It ascends upwards along the spine, and is inserted by small double tendons into the posterior and inferior part of all the transverse processes of the vertebræ of the back, and sometimes of the last vertebra of the neck. From its outside it sends off several bundles of fleshy fibres, interspersed with a few tendinous filaments, which are usually inserted into the lower edge of the ten uppermost ribs, not far from their tubercles. In some subjects, however, they are found inserted into a less number, and in others, though more rarely, into every one of the ribs. Towards the upper part of this muscle is observed a broad and thin portion of fleshy fibres, which cross and intimately adhere to the fibres of the longissimus dorsi. This portion arises from the upper and posterior part of the transverse processes of the five or six uppermost vertebræ of the back, by as many tendinous origins, and is usually inserted by six tendinous and fleshy slips, into the transverse processes of the six inferior vertebræ of the neck. This portion is described, by Winslow and Albinus, as a distinct muscle; by the former, under the name of *transversalis major colli*, and by the latter, under that of *transversalis cervicis*. But its fibres are so intimately connected with those of the longissimus dorsi, that it may very properly be considered as an appendage to the latter. The use of this muscle is to extend the vertebræ of the back, and to keep the trunk of the body erect; by means of its appendage, it likewise serves to turn the neck obliquely backwards, and a little to one side.

Longissimus manus. See *Flexor tertii internodii pollicis*.

Longissimus oculi. See *obliquus superior oculi*.

LONGITUDINAL. *Longitudinalis*. Parts are so named from their direction.

Longitudinal sinus. Longitudinal sinus of the dura mater. A triangular canal, proceeding in the falciform process of the dura mater, immediately under the bones of the skull, from the crista galli to the tentorium, where it branches into the lateral sinuses. The longitudinal sinus has a number of trabeculæ or fibres crossing it. Its use is to receive the blood from the veins of the pia mater, and convey it into the lateral sinuses, to be carried through the internal jugulars to the heart.

LO'NGUS. Long. Some parts are so named from their camparative length; as *longus colli*, &c.

Longus colli. *Præ dorso cervical*, of Dumas. This is a pretty considerable muscle, situated close to the anterior and lateral part of the vertebræ of the neck. Its outer edge is in part covered by the rectus internus major. It arises tendinous and fleshy within the thorax, from the bodies of the three superior vertebræ of the back, laterally; from the bottom and fore-part of the transverse processes of the first and second vertebræ of the back, and of the last vertebræ of the neck; and likewise from the upper and anterior points of the transverse processes of the sixth, fifth, fourth, and third vertebræ of the neck, by as many small distinct tendons; and is inserted tendinous into the fore-part of the second vertebra of the neck, near its fellow. This muscle, when it acts singly, moves the neck to one side; but, when both act, the neck is brought directly forwards.

LONI'CERA. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia*.

Lonicera diervilla. The systematic name of a species of honey-suckle. *Diervilla*. The young branches of this species *Lonicer—racemis terminalibus, foliis serratis*, of Linnæus, are employed in North America as a certain remedy in gonorrhœa and suppression of urine. It has not yet been exhibited in Europe.

Lonicera periclimenum. Honeysuckle. This beautiful and common plant was formerly used in the cure of asthma, for cleansing sordid ulcers, and removing diseases of the skin, virtues it does not now appear to possess.

LOOSENESS. See *Diarrhœa*.

LO'PEZ. *Radix lopeziana; Radix indica lopeziana*. The root of an unknown tree, growing, according to some, at Goa. It is met with in pieces of different thickness, some at least of two inches diameter. The woody part is whitish, and very light; softer, more spongy and whiter next the bark, including a denser, somewhat reddish, medullary part. The bark is rough, wrinkled, brown, soft, and, as it were, woolly, pretty thick, covered with a thin paler cuticle. Neither the woody nor cortical part has any remarkable smell or taste, nor any appearance of resinous matter. It appears that this medicine has been remarkably effectual in stopping colliquative diarrhœas, which had resisted the usual remedies. Those attending the last stage of consumptions were particularly relieved by its use. It seemed to act, not by an astringent power, but by a faculty of restraining and appeasing spasmodic and inordinate motions of the intestines. Dr. Gaubius, who gives this account, compares its action to that of Simarouba, but thinks it more efficacious than this medicine.

Lopez-root. See *Lopez*.

Lopeziana radix. See *Lopez*.

Lopha'dia. (From λοφος, the hinder part of the neck.) *Lophia*. The first vertebra of the neck.

LORDO'SIS. (From λορδος, curved, bent.) An affection of the spine, in which it is bent inwards.

Lo'rica. (From *lorico*, to crust over.) A kind of lute with which vessels are coated before they are put into the fire.

LORICA'TION. Coating. Nicholson recommends the following composition for the coating of glass vessels, to prevent their breaking when exposed to heat. Take of sand and clay, equal parts; make them into a thin paste, with fresh blood, prevented from coagulating by agitation, till it is cold, and diluted with water; add to this some hair, and powdered glass; with a brush, dipped in this mixture, besmear the glass; and when this layer is dry, let the same operation be repeated twice, or oftener, till the coat applied is about one-third part of an inch in thickness.

LORRY, Anne-Charles, was born near Paris, in 1725. He studied and practised as a physician, with unremitting zeal and peculiar modesty, and obtained a high reputation. At 23 he was admitted doctor of medicine at Paris, and subsequently became doctor-regent of the faculty. He was author of several works, some of which still maintained their value; particularly his treatise on Cutaneous Diseases, which combines much erudition and accurate observation, with great clearness of arrangement, and perspicuity of language. He died in 1783.

LOTION. (*Lotio*; from *lavo*, to wash.) An external fluid application. Lotions are usually applied by wetting linen in them, and keeping it on the part affected.

LO'TUS. (From λω, to desire.) 1. A tree the fruit of which was said to be so delicious as to make those who tasted it forsake all other desires: hence the proverb, *Λωτον εφαγον*, *lotum gustavi*: I have tasted lotus.

2. The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria*.

LOUIS, Anthony, was born at Metz in 1723. He attained great reputation as a surgeon, and was honoured with numerous appointments, and marks of distinction, as well in his own, as in foreign countries. He wrote the surgical part of the "Encyclopédie," and presented several interesting papers to the Royal Academy of Surgery, of which he was secretary: besides which, he was author of several works on anatomical, medical, and other subjects. In a memoir on the legitimacy of retarded births, he maintains that the detention of the fœtus more than ten days beyond the ninth month is physically impossible.

LOVAGE. See *Ligusticum levisticum*.

LOVE-APPLE. See *Solanum lycopersicum*.

LOWER, Richard, was born in Cornwall about the year 1631. He graduated at Oxford, and having materially assisted the celebrated Dr. Willis in his dissections, he was introduced into practice by that physician. In 1665 he published a defence of Willis's work on Fevers, displaying much learning and ingenuity. But his most important performance was entitled, "Tractatus de Corde, item de motu et calore Sanguinis, et Chyli in eum transitu," printed four years after. He demonstrated the dependance of the motions of the heart upon the nervous influence, and referred the red colour of arterial blood to the action of the air in the lungs; he also gave an account of his experiments, made at Oxford, in February 1665, on the transfusion of blood from one living animal to another, of which an abstract had before appeared in the Philosophical Transactions. He afterwards practised this upon an insane person, before the Royal Society, of which he was admitted a fellow in 1667, as well as of the College of Physicians. The reputation acquired by these and some other minor publications procured him extensive practice, particularly after the death of Dr. Willis; but his political opinions brought him into discredit at court, and he declined considerably before the close of his life in 1691. The operation of transfusion was soon exploded, experience having shown that it was attended with pernicious consequences.

Loxa'rthros. (From λυξος, oblique, and αρθρον, a joint.) *Loxarthrus*. An obliquity of the joint, without spasm or luxation.

LOXIA. (From γυξος, oblique.) The specific name in the genus *Entasia* of Good's Nosology, for wry neck.

LUCULLITE. A species of limestone.

Lu'dus helmontii. *Ludus paracelsi*. The waxen vein. A stony matter said to be serviceable in calculus.

LUDWIG, Christian Theophilus, was born in Silesia in 1709, and educated for the medical profession. Having a strong bias towards natural history, he went on an expedition to the north of Africa; and soon after his return, in 1733, he became professor of medicine at Leipsic. The first thesis defended there under his presidency related to the manner in which marine plants are nourished; which he showed not to be by the root, as is the case in the generality of the vegetable kingdom. He afterwards published several botanical works, in which he finds many objections to the Linnæan arrangement, rather preferring that of Rivinus; but on very unsatisfactory grounds. Elementary works were likewise written by him on the different branches of medical knowledge. A more important work is entitled "Adversaria Medico-practica," in three octavo volumes. He has given an account of his trials of Stramonium and Belladonna in epilepsy, by no means favourable to either. He died in 1773.

LU'ES. (*Lues*, *is*. f.; from λυω, to dissolve, because it produces dissolution.) A pestilence, poison, plague.

Lues deifica. One of the many pompous names formerly given to epilepsy.

Lues neurodes. A typhus fever.

Lues venerea. The plague of Venus, or the venereal disease. See *Syphilis*.

LUISINUS, Louis, was born at Udina, where he obtained considerable reputation about the middle of the 16th century. He translated Hippocrates's aphorisms into Latin hexameters; and published a treatise on regulating the affections of the mind by moral philosophy and the medical art: but his most celebrated work is entitled "Aphrodisiacus," printed at Venice, in two folio volumes: the first containing an account of preceding treatises on syphilis, the second comprehended principally the manuscript works on the subject, which had not then been committed to the press.

LU'JULA. (Corrupted or contracted from *Allelujah*, *Praise the Lord*; so called from its many virtues.) See *Oxalis acetosella*.

LUMBA'GO. (From *lumbus*, the loin.) A rheumatic affection of the muscles about the loins. See *Rheumatismus*.

LUMBAR. *Lumbalis*. Belonging to the loins.

Lumbar abscess. *Psoas abscess*. A species of *arthropuosis*, that receives its name from the situation in which the matter is found, namely, upon the side of the psoas muscle, or betwixt that and the iliacus internus. Between these muscles, there lies a quantity of loose cellular membrane, in which an inflammation often takes place, either spontaneously or from mechanical injuries. This terminates in an abscess that can procure no outlet but by a circuitous course in which it generally produces irreparable mischief, without any violent symptoms occurring to alarm the patient. The abscess sometimes forms a swelling above Poupart's ligament; sometimes below it; and frequently the matter glides under the fascia of the thigh. Occasionally, it makes its way through the sacro-ischiatic foramen, and assumes rather the appearance of a fistula in ano. The uneasiness in the loins, and the impulse communicated to the tumour by coughing, evince that the disease arises in the lumbar region; but it must be confessed, that we can hardly ever know the existence of the disorder, before the tumour, by presenting itself externally, leads us to such information. The lumbar abscess is sometimes connected with diseased vertebræ, which may either be a cause or effect of the collection of matter.

The disease, however, is frequently unattended with this complication.

The situation of the symptoms of lumbar abscess renders this affection liable to be mistaken for some other, viz. lumbago and nephritic pains, and, towards its termination, for crural or femoral hernia. The first, however, is not attended with the shivering that occurs here; and nephritic complaints are generally discoverable by attention to the state of the urine. The distinction from crural hernia is more difficult. In both, a soft inelastic swelling is felt in the same situation: but in hernia, it is attended with obstructed fæces, vomiting, &c. and its appearance is always sudden, while the lumbar tumour is preceded by various complaints before its appearance in the thigh. In a horizontal posture, the abscess also totally disappears, while the hernia does not.

Lumbar region. The loins.

LUMBARIS EXTERNUS. See *Quadratus lumborum.*

LUMBARIS INTERNUS. See *Psoas magnus.*

LUMBRICA'LIS. (*Lumbricalis musculus*; from its resemblance to the *lumbricus*, or earthworm.) A name given to some muscles from their resemblance to a worm.

LUMBRICALIS MANUS. *Fidicinales. Flexor primi internodii digitorum manus, vel perforatus lumbricalis*, of Cowper; *Anuli tendino-phalangiens*, of Dumas. The small flexors of the fingers which assist the bending the fingers when the long flexors are in full action. They arise thin and fleshy from the outside of the tendons of the flexor profundus, a little above the lower edge of the carpal ligaments, and are inserted by long slender tendons into the outer sides of the broad tendons of the interosseal muscles about the middle of the first joints of the fingers.

LUMBRICALES PEDIS. *Plantitendino-phalangien*, of Dumas. Four muscles like the former, that increase the flexion of the toes, and draw them inwards.

LUMBRI'CUS. (*à Lubricitate*; from its slipperiness.) *Ascaris lumbricoides; Lumbricus teres.* The long round worm. A species of worm which inhabits occasionally the human intestines. It has three nipples at its head, and a triangular mouth in its middle. Its length is from four to twelve inches, and its thickness, when twelve inches long, about that of a goose-quill. They are sometimes solitary, at other times very numerous. See *Worms.*

LUMBRICUS TERRESTRIS. *Vermis terrestris.* The earth-worm. Formerly given internally when dried and pulverised as a diuretic.

LU'MBUS VENERIS. See *Achillea millefolium.*

LU'NA. (*Luna, æ.* f.; *à lucendo.*) 1. The moon.

2. The old alchemistical name of silver.

LUNA CORNEA. Muriate of silver.

LUNA PLENA. A term used by the old alchemists in the transmutation of metals.

Lunar caustic. See *Argenti nitras.*

LUNA'RE OS. One of the bones of the wrist.

LUNARIA REDIVIVA. Bulbonach of the Germans. Satin and honesty. It was formerly esteemed as a warm diuretic.

LUNA'TICUS. (From *luna*, the moon: so called because the malady returns, or is aggravated, or influenced by the moon.)

1. A lunatic.

2. A disease which appears to be influenced by the moon.

LUNG. *Pulmo.* The lungs are two viscera situated in the chest, by means of which we breathe. The lung in the right cavity of the chest is divided into three lobes, that in the left cavity into two. They hang in the chest, attached at their superior part to the neck, by means of the trachea, and are separated by the mediastinum. They are also attached to the heart by means of the pulmonary vessels. The substance of the lungs is of four kinds, viz. vesicular vascular, bronchial, and parenchymatous. The vesicular substance is composed of the air-cells. The vascular invests those cells like a net-work. The bronchial is formed by the ramifications of the bronchia throughout the lungs, having the air cells at their extremities; and the spongy substance that connects these parts is termed the *parenchyma.* The lungs are covered with a fine membrane, a reflection of the pleura, called *pleura pulmonalis.* The internal surface of the air-cells is covered with a very fine, delicate and sensible membrane, which is continued from the larnyx through the trachea and bronchia. The arteries of the lungs are the bronchial, a branch of the aorta, which carries blood to the lungs for their nourishment; and the pulmonary, which circulates the blood through the air-cells to undergo a certain change. The pulmonary veins return the blood that has undergone this change, by four trunks, into the left auricle of the heart. The bronchial veins terminate in the vena azygos. The nerves of the lungs are from the eighth pair and great intercostal. The absorbents are of two orders; the superficial, and deep-seated: the former are more readily detected than the latter. The glands of these viscera are called bronchial. They are muciparous, and situated about the bronchia. See *Respiration.*

LUNG-WORT. See *Pulmonaria officinalis.*

LUNULATUS. Crescent-shaped, or half-moon-like: a term applied to leaves, pods, &c. which are so shaped, whether the points are directed towards the stalk, or from it; as in the leaves of *Passiflora lunata*, and legumen of *Medicago foliata.*

LU'PIA. (From λυπεω, to molest.)

1. A genus of disease, including encysted tumours, the contents of which are very thick, and sometimes solid; as *meliceris, atheroma, steatoma*, and *ganglion.*

2. (From *lupus*, a wolf: so called because it does not cease to destroy the part it seizes.) A malignant ulcer which eats away the soft parts on which it appears, laying bare the bones and cartilages, and which is equally fatal with cancer.

LUP'INUS. (So called by Pliny and other ancient writers. Professor Martin says the word owes its origin to *Lupus*, a wolf, because plants of this genus ravage the ground by overrunning it, after the manner of that animal. It is also derived from λυπη, grief: whence Virgil's epithet, *tristes lupini*; from the fanciful idea of its acrid juices, when tasted, producing a sorrowful appearance on the countenance.) The name of a genus of plants. Class, *Diadelphia*; Order, *Decandria.*

2. Under this term the white lupin is directed in some pharmacopœias.

LUPINUS ALBUS. The systematic name of the white lupin. The seed, the ordinary food of mankind in the days of Galen and Pliny, is now forgotten. Its farinaceous and bitter meal is occasionally exhibited to remove worms from the intestines, and made into poultices to resolve indolent tumours.

LUPULIN. Lupuline. The name given by Dr. Ives to an impalpable yellow powder, in which he believes the virtue of the hop to reside, and which may be obtained by beating and sifting the hops used in brewing. It appears to be peculiar to the female plant, and is probably secreted by the nectaria. In preserving beer from the acetous fermentation, and in communicating an agreeable flavour to it, lupulin was found to be equivalent to ten times its weight of hop leaves.

LU′PULUS. (From λυπη, dislike: so named from its bitterness.) See *Humulus*.

LU′PUS. 1. The wolf, so named from its rapacity.

2. The cancer is also so called, because it eats away the flesh like a wolf.

Luridæ. The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of those which prove some deadly poison; the corolla mostly monopetalous; as *Datura*, *Solanum*, *Nicotiana*.

Lustra′go. (From *lustro*, to expiate: so called because it was used in the ancient purifications.) Flat or base vervain.

LUSUS. A sport.

Lusus naturæ. A sport of nature; a monster. See *Monster*.

LUTE. See *Lutum*.

Lu′tea corpora. See *Corpus luteum*.

LUTE′OLA. (From *lutum*, mud; because it grows in muddy places, or is of the colour of mud.) See *Reseda luteola*.

LU′TUM. (From λυτος, soluble.) *Cæmentum*. Mud. Lute. A composition with which chemical vessels are covered, to preserve them from the violence of the fire, and to close exactly their joinings to each other, to retain the substances which they contain when they are volatile and reduced to vapour.

LUXATION. (*Luxatio*; from *luxo*, to put out of joint.) A dislocation of a bone from its proper cavity.

Lyca′nche. (From λυκος, a wolf, and αγχω, to strangle.) A species of quincy, in which the patient makes a noise like the howling of a wolf.

Lycanthro′pia. (From λυκος, a wolf, and ανθρωπος, a man.) A species of insanity, in which the patients leave their houses in the night, and wander about like wolves, in unfrequented places.

LY′CHNIS. (From λυχνος, a torch; because the ancients used its leaves rolled up for torches.) 1. A name of several vegetable productions.

2. The name of a genus of plants. Class, *Decandria*; Order, *Pentagynia*.

Lychnis segetum. See *Agrostemma githago*.

LYCHNOIDES. (From *lychnis*, the name of a plant, and ειδος, resemblance.) Like the herb *lychnis*.

Lychnoides segetum. See *Agrostemma githago*.

LYCO′CTONUM. (From λυκος, a wolf, and κτεινω, to slay: so called because it was the custom of hunters to secrete it in raw flesh, for the purpose of destroying wolves.) The *Aconitum lycoctonum*.

LYCOPE′RDON. (From λυκος, a wolf, and περδω, to break wind: so named because it was supposed to spring from the dung of wolves.) 1. The name of a genus of plants in the Linnæan system. Class, *Cryptogamia*; Order, *Fungi*.

2. The pharmacopœial name of the puff-ball. See *Lycoperdon bovista*.

Lycoperdon bovista. The systematic name of the puff-ball. *Crepitus lupi*. A round or egg-shaped fungus, the *Lycoperdon*; *subrotundum, lacerato dehiscens*, of Linnæus; when fresh, of a white colour, with a very short, or scarcely any pedicle, growing in dry pasture grounds. When young, it is sometimes covered with tubercles on the outside, and is pulpy within. By age it becomes smooth externally, and dries internally into a very fine, light, brownish dust, which is used by the common people to stop hæmorrhages. See *Lycoperdon*.

Lycoperdon tuber. The systematic name of the truffle. *Tuber cibarium*, of Dr. Withering. A solid fungus of a globular figure, which grows under the surface of the ground without any roots or the access of light, and attains a size from a pea to the largest potatoe. It has a rough, blackish coat, and is destitute of fibres. Cooks are well acquainted with its use and qualities. It is found in woods and pastures in some parts of Kent, but is not very common in England. In France and Spain, truffles are very frequent, and grow to a much larger size than they do here. In these places the peasants find it worth their while to search for them, and they train up dogs and swine for this purpose, who after they have been inured to their smell by their masters frequently placing them in their way, will readily scrape them up as they ramble the fields and woods.

LYCOPE′RSICUM. (From λυκος, a wolf, and περσικον, a peach: so called from its exciting a violent degree of lust.) *Lycopersicon*. Wolf's peach. Love apple. See *Solanum lycopersicon*.

LYCOPO′DIUM. (From λυκος, a wolf, and πους, a foot: so called from its supposed resemblance.) 1. The name of a genus of plants in the Linnæan system. Class, *Cryptogamia*; Order, *Musci*.

2. The pharmacopœial name of the club-moss. See *Lycopodium clavatum*.

Lycopodium clavatum. The systematic name of the club-moss. Wolf's claw. *Muscus clavatus*. This plant affords a great quantity of pollen, which is much esteemed in some places to sprinkle on young children, to prevent, and in the curing parts which are fretting. A decoction of the herb is said to be a specific in the cure of the plica polonica.

Lycopodium selago. The systematic name of the upright club-moss. *Muscus erectus*. The decoction of this plant acts violently as a vomit and a purgative, and was formerly on that account employed to produce abortions.

LYCO′PSIS. (From λυκος, a wolf, and οψις, an aspect: so called from its being of the colour of a wolf, or from the circumstance of the flowers being ringent, and having the appearance of a grinning mouth. The herbage is also furnished, says Ambrosinus, with a sort of rigid hairiness similar to the coat of a wolf.) 1. The name of a genus of plants. Class, *Pentandria*; Order, *Monogynia*.

2. The pharmacopœial name of the Wall-bugloss, *Echium ægyptiacum*, the *Asperugo ægyptiaca* of Wildenow.

LY′COPUS. (From λυκος, a wolf, and πους, a foot: so named from its likeness.) The name of a genus of plants in the Linnæan system. Class, *Diandria*; Order, *Monogynia*. Wolf's-claw, or water horehound.

Lycopus europeus. This plant is sometimes used as an astringent.

Lydian stone. A flinty slate.

Lygi′smus. (From λυγιζω, to distort.) A dislocation.

Ly′gus. (From λυγιζω, to bend: so called from its flexibility.) The agnus castus.

LYMPH. *Lympha*. The liquid contained in the lymphatic vessels. Two processes may be employed to procure lymph. One is to lay bare a lymphatic vessel, divide it, and receive the liquid that flows from it; but this is a method difficult to execute, and besides, as the lymphatic vessels are not always filled with lymph, it is uncertain: the other consists in letting an animal fast during four or five days, and then extracting the fluid contained in the thoracic duct.

The liquid obtained in either way has at first a slightly opaline rose colour. It has a strong spermatic odour; a salt taste; it sometimes presents a slight yellow tinge, and at other times a red madder colour.

But lymph does not long remain liquid; it congeals. Its rose colour becomes more deep, an immense number of reddish filaments are developed, irregularly arborescent, and very analogous in appearance to the vessels spread in the tissue of organs.

When we examine carefully the mass of lymph thus coagulated, we find it formed of two parts; the one solid, and forming a great many cells, in which the other remains in a liquid state. If the solid part be separated, the liquid congeals again.

The quantity of lymph procured from one animal is but small; a dog of a large size scarcely yields an ounce. Its quantity appears to increase according to the time of fasting.

The solid part of the lymph, which may be called *clot*, has much analogy with that of the blood. It becomes scarlet-red by the contact of oxygen gas, and purple when plunged in carbonic acid.

This specific gravity of lymph is to that of distilled water as 1022.28 : 1000.00.

Chevreuil analysed the lymph of the dog:

Water,	926.4
Fibrin,	004.2
Albumen,	61.0
Muriate of Soda,	6.1
Carbonate of Soda,	1.8
Phosphate of Lime,	0.5
Phosphate of Magnesia,	
Carbonate of Lime,	
Total	1000.0

Its specific gravity is greater than water; in consistence, it is thin and somewhat viscid. The quantity in the human body appears to be very great, as the system of the lymphatic vessels forms no small part of it. Its constituent principles appear to be albuminous water and a little salt. The lymphatic vessels absorb this fluid from the tela cellulosa of the whole body, from all the viscera and the cavities of the viscera; and convey it to the thoracic duct, to be mixed with the chyle.

The use of the lymph is to return the superfluous nutritious jelly from every part, and to mix it with the chyle in the thoracic duct, there to be further converted into the nature of the animal; and, lastly, it has mixed with it the superfluous aqueous vapour, which is effused into the cavities of the cranium, thorax, abdomen, &c.

LYMPHATIC. (*Lymphaticus*; from *lympha*, lymph.) 1. Of the nature of lymph.

2. An absorbent vessel, that carries a transparent fluid, or lymph. The lymphatic vessels of the human body are small and transparent, and originate in every part of the body. With the lacteal vessels of the intestines, they form what is termed the *absorbent system*. Their termination is in the thoracic duct. See *Absorbent*, *Lacteal*, and *Thoracic duct*.

Lymphatics of the head and neck.—Absorbents are found on the scalp and about the viscera of the neck, which unite into a considerable *branch*, that accompanies the jugular vein. Absorbents have not been detected in the human brain: yet there can be no doubt of there being such vessels: it is probable that they pass out of the cranium through the canalis caroticus and foramen lacerum in basi cranii, on each side, and join the above *jugular branch*, which passes through some glands as it proceeds into the chest to the angle of the subclavian and jugular veins.

The absorbents from the right side of the head and neck, and from the right arm, do not run across the neck, to unite with the great trunk of the system; they have an equal opportunity of dropping their contents into the angle betwixt the right subclavian and the jugular vein. These vessels then uniting, form a trunk, which is little more than an inch, nay, sometimes not a quarter of an inch, in length, but which has nearly as great a diameter as the proper trunk of the left side.

This vessel lies upon the right subclavian vein, and receives a very considerable number of lymphatic vessels; not only does it receive the lymphatics from the right side of the head, thyroid gland, neck, &c. and the lymphatics of the arm, but it receives also those from the right side of the thorax and diaphragm, from the lungs of this side, and from the parts supplied by the mammary artery. Both in this and in the great trunk, there are many valves.

Of the upper extremities.—The absorbents of the upper extremities are divided into superficial and deep-seated. The *superficial absorbents* ascend under the skin of the hand in every direction to the wrist, from whence a *branch* proceeds upon the posterior surface of the fore-arm to the head of the radius, over the internal condyle of the humerus, up to the axilla, receiving several branches as it proceeds. Another *branch* proceds from the wrist along the anterior part of the fore-arm, and forms a *net-work*, with a *branch* coming over the ulna from the posterior part, and ascends on the inside of the humerus to the glands of the axilla. The *deep-seated absorbents* accompany the larger blood-vessels, and pass through two glands about the middle of the humerus, and ascend to the glands of the axilla. The superficial and deep-seated absorbents having passed through the axillary glands, form *two trunks*, which unite into *one*, to be inserted with the jugular absorbents into the thoracic duct, at the angle formed by the union of the subclavian with the jugular vein.

Lymphatics of the inferior extremities.—These are also superficial and deep-seated. The *superficial ones* lie between the skin and muscles. Those of the toes and foot form a *branch*, which ascends upon the back of the foot, over the tendon of the cruræus anticus, forms with other branches *a plexus* above the ancles, then proceeds along the tibia over the knee, sometimes passes through a gland, and proceeds up the inside of the thigh, to the subinguinal glands. The *deep-seated* absorbents follow the course of the arteries, and accompany the femoral artery, in which course they pass through some glands in the leg and above the knee, and then proceed to some deep-seated subinguinal glands. The absorbents from about the external parts of the pubes, as the penis and perineum, and from the external parts of the pelvis, in general, proceed to the inguinal glands. The subinguinal and inguinal glands send forth several branches, which pass through the abdominal ring into the cavity of the abdomen.

Of the abdominal and thoracic viscera.—The absorbents of the lower extremities accompany the external iliac artery, where they are joined by many branches from the *uterus*, *urinary bladder*, *spermatic chord*, and some branches accompanying the internal iliac artery; they then ascend to the sacrum, where they form a *plexus*, which proceeds over the psoas muscles, and meeting with the lacteals of the mesentery, form the thoracic duct, or trunk of the absorbents, which is of a serpentine form, about the size of a crow-quill, and runs up the dorsal vertebræ, through the posterior opening of the diaphragm, between the aorta and vena azygos, to the angle formed by the union of the left subclavian and jugular veins. In this course it receives:—the *absorbents of the kidneys*, which are superficial and deep-seated, and unite as they proceed towards the thoracic duct; and *the absorbents of the spleen*, which are upon its peritoneal coat, and unite with those of the pancreas:—a *branch* from the plexus of vessels passing above and below the duodenum, and formed by the absorbents of the *stomach*, which come from the lesser and greater curvature, and are united about the pylorus with those of the pancreas and liver, which converge from the external surface and internal parts towards the portæ of the liver, and also by several branches from the *gall-bladder*.

Use of Lymphatics.—The office of these vessels is to take up substances which are applied to their mouths; thus the vapour of circumscribed cavities, and of the cells of the cellular membrane, are removed by the lymphatics of those parts; and thus mercury and other substances are taken into the system when rubbed on the skin.

The principle by which this absorption takes place, is a power inherent in the mouths of absorbing vessels, a vis insita, dependent on the high degree of irritability of their internal membrane by which the vessels contract and propel the fluid forwards. Hence the use of this function appears to be of the utmost importance, viz. to supply the blood with chyle; to remove the superfluous vapour of circumscribed cavities, otherwise dropsies, as hydrocephalus, hydrothorax, hydrocardia, ascites, hydrocele, &c. would constantly be taking place: to remove the superfluous vapour from the cells of the cellular membrane dispersed throughout every part of the body, that anasarca may not take place: to remove the hard and soft parts of the body, and to convey into the system medicines which are applied to the surface of the body.

Lymphatic glands. *Glandulæ lymphaticæ.* See *Conglobate gland.*

Lypo'ma. See *Lipoma.*

LY'RA. (From λυρα, a lyre, or musical instrument.) *Psalterium.* The triangular medullary space between the posterior crura of the fornix of the cerebrum, which is marked with prominent medullary fibres that give the appearance of a lyre.

LYRATUS. (From *lyra*, a musical instrument.) Lyrate or lyre-shaped. A leaf is so named which is cut into transverse segments, generally longer towards the extremity of the leaf, which is rounded; as in *Erysimum barbaria.*

Ly'rus. (From *lyra*, the lyre; so called because its leaves are divided like the strings of a lyre.) See *Arnica montana.*

Lysigy'ia. (From λυω, to loosen, and γυιον, a member.) The relaxation of limbs.

LYSIMA'CHIA. (From *Lysimachus*, who first discovered it.) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia.*

Lysimachia nummularia. The systematic name of the money-wort. *Nummularia; Hirundinaria; Centimorbia.* Money-wort. This plant is very common in our ditches. It was formerly accounted vulnerary; and was said to possess antiscorbutic and restringent qualities. Boerhaave looks upon it as similar to a mixture of scurvy-grass with sorrel.

Lysimachia purpurea. See *Lythrum salicaria.*

LYSSA. (Λυσσα, *rabies.*) The specific name in Good's Nosology for hydrophobia. *Entasia lyssa.*

Lyssode'ctus. (From λυσσα, canine madness, and δακνυμι, to bite.) One who is mad in consequence of having been bitten by a mad animal.

LYTHRODES. See *Scapolite.*

LY'THRUM. (From λυθρον, blood: so called from its resemblance in colour.) The name of a genus of plants in the Linnæan system. Class, *Dodecandria;* Order, *Digynia.*

Lythrum salicaria. *Lysimachia purpurea.* The systematic name of the common or purple willow-herb. The herb, root, and flowers possess a considerable degree of astringency, and are used medicinally in the cure of diarrhœas and dysenteries, fluor albus, and hæmoptysis.

LYTTA. (The name of a genus of insects.) See *Cantharis.*

M.

M. This letter has two significations. When herbs, flowers, chips, or such-like substances are ordered in a prescription, and M. follows them, it signifies *manipulus*, a handful; and when several ingredients have been directed, it is a contraction of *misce;* thus, *m. f. haust.*, signifies mix and let a draught be made.

Maca'ndon. (Indian.) A tree growing in Malabar, the fruit of which is roasted and eaten as a cure for dysenteries, and in cholera morbus, and other complaints.

Macapa'tli. Sarsaparilla.

Macaxocotli'fera. The name of a tree in the West Indies, the fruit of which is sweet and laxative. A decoction of the bark of this tree cures the itch, and the powder thereof heals ulcers.

MACBRIDE, David, was born in the county of Antrim, of an ancient Scotch family, in 1726. After serving his apprenticeship to a surgeon, he went into the navy, where he remained some years. At this period he was led to investigate particularly the treatment of scurvy, upon which he afwards published a treatise. After the peace of Aix-la-Chapelle, he attended the lectures in Edinburgh and London; and about the end of 1749, settled in Dublin as a surgeon and accoucheur, but his youth and modesty greatly retarded his advancement at first. In 1764, he published his Experimental Essays, which were every where received with great applause; and the University of Glasgow conferred upon him a Doctor's degree. For several years after this he gave private lectures on physic; which he published in 1772: this work displayed great acuteness of observation, and very philosophical views of pathology; and contained a new arrangement of diseases, which appeared to Dr. Cullen of sufficient importance to be introduced into his system of nosology. His merit being thus displayed, he got into very extensive practice; indeed, he was so much harassed, that he suffered for some time an almost total incapacity for sleep; when an accidental cold brought on high fever and delirium, which terminated his existence towards the close of 1778.

MACE. See *Myristica mochata.*

Macedonian parsley. See *Bubon macedonicum.*

MACEDONI′SIUM SEMEN. See *Smyrnium olusatrum.*

MA′CER. (From *masa,* Hebrew.) Grecian macer or mace. The root which is imported from Barbary by this name, is supposed to be the simarouba, and is said to be anti-dysenteric.

MACERA′TION. (*Maceratio*; from *macero,* to soften by water.) In a pharmaceutical sense, this term implies an infusion either with or without heat, wherein the ingredients are intended to be almost wholly dissolved in order to extract their virtues.

MACERO′NA. See *Smyrnium olusatrum.*

MACHÆ′RION. *Machæris.* The amputating-knife.

MACHA′ON. The proper name of an ancient physician, said to be one of the sons of Æsculapius; whence some authors have fancied to dignify their own inventions with his name, as particularly a collyrium, described by Scribonius, intituled, *Asclepias, Machaonis;* and hence also, medicine in general is by some called *Ars Machaonia.*

MACHINAME′NTUM ARISTIONIS. A machine for reducing dislocation.

MA′CIES. Emaciation. See *Atrophy* and *Tabes.*

MA′CIS. Mace. See *Myristica.*

MACKAREL. This delicious fish is the *Scomber scomber* of Linnæus. When fresh it is of easy digestion, and very nutritious. Pickled and salted, it becomes hard and difficult for the stomach to manage.

MACQUER, JOSEPH, was born at Paris in 1710, where he became doctor of medicine, professor of pharmacy, and censor-royal. He was likewise a member of some foreign academies, and conducted the medical and chemical department of the Journal des Savans. He pursued chemistry, not so much with a view of multiplying pharmaceutical preparations, as had been mostly the case before, but, rather as a branch of natural philosophy; and gained a considerable reputation by publishing several useful and popular works on the subject. The most laborious of these was a dictionary in two octavo volumes; subsequently translated into English by Keir, with great improvements. He published also "Formulæ Medicamentorum Magistralium," and had a share in the composition of the Pharmacopœia Parisiensis of 1758. His death occurred in 1784.

MACROCE′PHALUS. (From μακρος, long, and κεφαλη, the head.) The name of a whale fish. See *Physeter macrocephalus.*

MACROPHYSOCE′PHALUS. (From μακρος, long, φυσις, nature, and κεφαλη, the head, so called from the length of the head.) One who has a head unnaturally long, and large. This word, according to Turton, is only used by Ambrose Parey.

MACRO′PIPER. (From μακρος, long, and πεπερι, pepper.) See *Piper longum.*

MACROPNŒ′A. (From μακρος, long, and πνεω, to breathe.) A difficulty of breathing, where the inspirations are at long intervals.

MA′CULA. A spot, a permanent discoloration of some portion of the skin, often with a change of its texture, but not connected with any disorder of the constitution.

MACULA MATRICIS. A mother's mark. See *Nævus maternus.*

MACULATUS. Spotted: applied in botany to stems, petals, &c. as the stem of the common hemlock, *Conium maculatum;* the *petales* of the *Digitalis purpurea.*

Mad-apple. See *Solanum melongena.*

MADARO′SIS. (From μαδος, bald, without hair.) A defect or loss of eye-brows or eye-lashes, causing a disagreeable deformity, and painful sensation of the eyes, in a strong light.

MADDER. See *Rubia.*

MADNESS. See *Melancholia,* and *Mania.*

Madness, canine. See *Hydrophobia.*

MA′DOR. Moisture. A sweating.

MADREPORA. *Madrepore.* 1. A genus in natural history, of the class, *Vermes;* and order, *Zoophyta.* An animal resembling a Medusa.

2. A species of coral. It consists of carbonate of lime, and a little animal membranaceous substance.

MAGATTI, CÆSAR, was born in 1579, in the duchy of Reggio. He distinguished himself by his early proficiency in philosophy and medicine at Bologna, where he graduated in his 18th year; and afterwards went to Rome. Returning at last to his native country, he soon acquired so much reputation in his profession, that he was invited, as professor of surgery, to Ferrara; and after greatly distinguishing himself in that capacity, he was induced, during a severe illness, to enter into the fraternity of Capuchins. He still continued, however, to practise, and acquired the confidence of persons of the first rank, especially the duke of Modena. But suffering severely from the stone, he underwent an operation at Bologna in 1647, which he did not long survive. He was author of a considerable improvement in the art of surgery, by his work entitled "De rara Medicatione Vulnerum," condemning the use of tents, and recommending a simple, easy method of dressing, without the irritation of frequently cleansing and rubbing the tender granulations: and in an appendix he refutes the notion of gun-shot wounds being envenomed, or attended with cauterization. He afterwards published a defence of this work against some objections of Sennertus.

MAGDA′LEON. (From μασσω, to knead.) A mass of plaster, or other composition, reduced to a cylindrical form.

MAGELLA′NICUS CORTEX. See *Wintera aromatica.*

MA′GISTERY. (*Magisterium;* from *magister,* a master.) An obsolete term used by ancient chemists to signify a peculiar and secret method of preparing any medicine, as it were, by a masterly process. The term was also long applied to all precipitates.

MAGISTRA′LIA. (From *magister,* a master.) Applied by way of eminence, to such medicines as are extemporaneous, or in common use.

MAGISTRA′NTIA. (From *magistro,* to rule: so called by way of eminence, as exceeding all others in virtue.) See *Imperatoria.*

MA'GMA. (From μασσω, to blend together.) *Ecpiesma*. 1. A thick ointment.

2. The fæces of an ointment after the thinner parts are strained off.

3. A confection.

MA'GNES. (From *Magnes*, its inventor.) The magnet, or load-stone. A muddy iron-ore, in which the iron is modified in such a manner as to afford a passage to a fluid called the magnetic fluid. The magnet exhibits certain phenomena; it is known by its property of attracting steel filings, and is found in Auvergne, in Biscay, in Spain, in Sweden, and Siberia.

MAGNES ARSENICALIS. Arsenical magnet. It is a composition of equal parts of antimony, sulphur, and arsenic, mixed and melted together, so as to become a glassy body.

MAGNES EPILEPSIÆ. An old and obsolete name of native cinnabar.

MAGNE'SIA. 1. The ancient chemists gave this name to such substances as they conceived to have the power of attracting any principle from the air. Thus an earth which, on being exposed to the air, increased in weight, and yielded vitriol, they called *magnesia vitriolata*: and later chemists, observing in their process for obtaining magnesia, that nitrous acid was separated, and an earth left behind, supposing it had attracted the acid, called it *magnesia nitri*, which, from its colour, soon obtained the name of *magnesia alba*.

2. The name of one of the primitive earths, having a metallic basis, called magnesium. It has been found native in the state of hydrate.

Magnesia may be obtained, by pouring into a solution of its sulphate a solution of subcarbonate of soda, washing the precipitate, drying it, and exposing it to a red heat. It is usually procured in commerce, by acting on magnesian limestone with the impure muriate of magnesia, or bittern of the sea-salt manufactories. The muriatic acid goes to the lime, forming a soluble salt, and leaves behind the magnesia of both the bittern and limestone. Or the bittern is decomposed by a crude subcarbonate of ammonia, obtained from the distillation of bones in iron cylinders. Muriate of ammonia and subcarbonate of magnesia result. The former is evaporated to dryness, mixed with chalk and sublimed. Subcarbonate of ammonia is thus recovered, with which a new quantity of bittern may be decomposed; and thus in ceaseless repetition, forming an elegant and economical process. 100 parts of crystallised Epsom salt, require for complete decomposition 56 of subcarbonate of potassa, or 44 dry subcarbonate of sodá, and yield 16 of pure magnesia after calcination.

Magnesia is a white, soft powder. Its sp. gr. is 2.3 by Kirwan. It renders the syrup of violets, and infusion of red cabbage, green, and reddens turmeric. It is infusible, except by the hydroxygen blowpipe. It has scarcely any taste, and no smell. It is nearly insoluble in water; but it absorbs a quantity of that liquid with the production of heat. And when it is thrown down from the sulphate by a caustic alkali, it is combined with water constituting a hydrate, which, however, separates at a red heat. It contains about one-fourth its weight of water.

When magnesia is exposed to the air, it very slowly attracts carbonic acid. It combines with sulphur, forming a sulphuret.

The metallic basis, or magnesium, may be obtained in the state of amalgam with mercury, by electrisation.

When magnesia is strongly heated in contact with two volumes of chlorine, this gas is absorbed, and one volume of oxygen is disengaged. Hence it is evident that there exists a combination of magnesium and chlorine, or a true chloride. The salt called muriate of magnesia, is a compound of the chloride and water. When it is acted on by a strong heat, by far the greatest part of the chlorine unites to the hydrogen of the water, and rises in the form of muriatic acid gas; while the oxygen of the decomposed water combines with the magnesium to form magnesia.

Magnesia is often associated with lime in minerals, and their perfect separation becomes an interesting problem in analysis.

Properties. Pure magnesia does not form with water an adhesive ductile mass. It is in the form of a very white spongy powder, soft to the touch, and perfectly tasteless. It is very slightly soluble in water. It absorbs carbonic acid gradually from the atmosphere. It changes very delicate blue vegetable colours to green. Its attraction to the acids is weaker than those of the alkalies. Its salts are partially decomposed by ammonia, one part of the magnesia being precipitated, and the other forming a triple compound. Its specific gravity is about 2.3. It is infusible even by the most intense heat; but when mixed with some of the other earths it becomes fusible. It combines with sulphur. It does not unite to phosphorus or carbon. It is not dissolved by alkalies in the humid way. When heated strongly, it becomes phosphorescent. With the dense acids it becomes ignited. With all the acids it forms salts of a bitter taste, mostly very soluble.

The magnesia of the present London Pharmacopœia was formerly called *Magnesia calcinata*; *usta*; *pura*. It is directed to be made thus:—Take of carbonate of magnesia, four ounces; burn it in a very strong fire, for two hours, or until acetic acid being dropped in, extricates no bubbles of gas. It is given as an absorbent, antacid, and eccoprotic, in cardialgia, spasms, convulsions, and tormina of the bowels of infants; pyrosis, flatulencies, and other diseases of the primæ viæ; obstipation, leucorrhœa, rickets, scrofula, crusta lactea, and podagra. The dose is from half a drachm to a drachm.

MAGNESIA CALCINATA. See *Magnesia*.

MAGNESIA, HYDRATE OF. A mineral found in New Jersey, consisting of magnesia and water.

MAGNESIA USTA. See *Magnesia*.

MAGNESIA VITRIOLATA. See *Magnesiæ sulphas*.

MAGNESIÆ SUBCARBONAS. *Magnesiæ carbonas*; *Magnesia alba*. Subcarbonate of magnesia. The London College direct it to be made as follows:—Take of sulphate of magnesia, a pound; subcarbonate of potassa, nine ounces; water, three gallons. Dissolve the subcarbonate of potassa in three pints of the water, and strain; dissolve also the sulphate of magnesia separately in five pints of the water, and strain; then add the rest of the water to this latter solution, apply heat, and when it boils, pour in the former solution, stirring them well together; next, strain through a linen cloth; lastly, wash the powder repeatedly with boiling water, and dry it upon bibulous paper, in a heat of 200°. It is in form of very fine powder, considerably resembling flour in its appearance and feel; it has no sensible taste on the tongue; it gives a faint greenish colour to the tincture of violets, and converts turnsole to a blue. It is employed medicinally as an absorbent, antacid, and purgative, in doses from half a drachm to two drachms.

MAGNESIÆ SULPHAS. *Sulphas magnesiæ*; *Sulphas magnesiæ purificata*; *Magnesia vitriolata*; *Sal catharticus amarus*. *Sal cathar-*

ticum amarum. Sulphate of magnesia. Epsom salt. Bitter purging salt.

The sulphate of magnesia exists in several mineral springs, and in sea-water.

It is from these saline solutions that the salt is obtained; the method generally adopted for obtaining it, is evaporation, which causes the salt to crystallise in tetrahedral prisms. It has a very bitter taste, and is soluble in its own weight of water at 60°, and in three-fourths of its weight of boiling water. Sulphate of magnesia, when perfectly pure, effloresces; but that of commerce generally contains foreign salts, such as the muriate of magnesia, which renders it so deliquescent, that it must be kept in a close vessel or bladder. By the action of heat it undergoes the watery fusion, and loses its water of crystallisation, but does not part with its acid. One hundred parts of crystallised sulphate of magnesia consist of 29.35 parts of acid, 17 of earth, and 53.65 of water. The alkalies, strontian, barytes, and all the salts formed by these salifiable bases, excepting the alkaline muriates, decompose sulphate of magnesia. It is also decomposed by the nitrate, carbonate, and muriate of lime.

Epsom salt is a mild and gentle purgative, operating with sufficient efficacy, and in general with ease and safety, rarely occasioning any gripes, or the other inconveniences of resinous purgatives. Six or eight drachms may be dissolved in a proper quantity of common water; or four, five, or more in a pint or quart of the purging mineral waters. These solutions may likewise be so managed, in small doses, as to produce evacuation from the other emunctories; if the patient be kept warm, they increase perspiration, and by moderate exercise in the cool air, the urinary discharge. Some allege that this salt has a peculiar effect in allaying pain, as in colic, even independently of evacuation.

It is, however, principally used for the preparation of the subcarbonate of magnesia.

MAGNESITE. A yellowish grey or white mineral, composed of magnesia, carbonic acid, alumina, a ferruginous manganese, lime, and water, found in serpentine rocks, in Moravia.

MAGNESIUM. The metallic basis of magnesia. See *Magnesia.*

MAGNET. See *Magnes.*

MAGNETISM. The property which iron possesses of attracting or repelling other iron, according to circumstances, that is, similar poles of magnets repel, but opposite poles attract each other.

Magnetism, animal. A sympathy lately supposed, by some persons, to exist between the magnet and the human body; by means of which, the former became capable of curing many diseases in an unknown way, somewhat resembling the performances of the old magicians. Animal magnetism is now entirely exploded.

Magnum os. The third bone of the lower row of bones of the carpus, reckoning from the thumb towards the little finger.

MAGNUS. The term is applied to parts from their relative size; and to diseases and remedies from their importance; as *magnum os, magnus morbus, magnum dei donum,* &c.

Magnum dei donum. So Dr. Mead calls the Peruvian bark.

Magnus morbus. The great disease. So Hippocrates calls the epilepsy.

Magy′daris. The root of the laser-wort.

Mahagoni. See *Swietenia.*

Mahaleb. A species of *Prunus.*

Mahmou′dy. *Scammonium.*

MAIDENHAIR. See *Adianthum.*

Maidenhair, Canada. See *Adianthum pedatum.*

Maidenhair, common. See *Asplenium trichomanes.*

Maidenhair, English. See *Adianthum.*

Maidenhair, golden. See *Polytrichum.*

Maidenhair-tree. *Ginan itsio.* The *Gingko biloba.* In China and Japan, where this tree grows, the fruit acquires the size of a damask plum, and contains a kernel resembling that of our apricot. These kernels always make part of the desert at all public feasts and entertainments. They are said to promote digestion, and to cleanse the stomach and bowels. The oil is used at the table.

Majanthemum. See *Convallaria majalis.*

MAJORA′NA. (*Quod mense Maio floreat,* because it flowers in May.) See *Origanum majorana.*

Majorana syriaca. See *Teucrium marum.*

MA′LA. (From *malus,* an apple: so called from its roundness.) A prominent part of the cheek. See *Jugale os.*

Mala æthiopica. A species of love-apple. See *Solanum lycopersicum.*

Mala assyria. The citron.

Mala aurantia. See *Citrus aurantium.*

Mala cotonea. The quince.

Mala insana nigra. See *Solanum melongena.*

Malabar plum. See *Eugenia jambos.*

Malabathri oleum. Oil of cassia.

Malaba′thrinum. (From *μαλαβαθρον,* malabathrum.) Ointment of malabathrum. It is compounded of myrrh, spikenard, malabathrum, and many other aromatic ingredients.

Malaba′thrum. (*Μαλαβαθρον*: from *Malabar,* in India, whence it was brought, and *betre,* a leaf, Ind.) See *Laurus cassia.*

Ma′laca radix. See *Sagittaria alexipharmaca.*

Malacca bèan. See *Avicennia tomentosa.*

Ma′lache. (*Malache, es,* f.; from *μαλακος,* soft: so called from the softness of its leaf. The mallow. See *Malva.*

MALACHITE. (From *μαλαχη,* the mallow: from its resemblance in colour to the mallow.) Mountain blue, a carbonate of copper ore found in Siberia.

MALACHOLITE. See *Sahlite.*

Mala′cia. (From *μαλαχιον,* a ravenous fish.) Depraved appetite, when such things are coveted as are not proper for food. See *Pica.*

MALACO′STEON. (From *μαλακος,* soft, and *οςεον,* a bone.) A softness of the bones. *Mollities ossium.* A disease of the bones, wherein they can be bent without fracturing them, in consequence either of the inordinate absorption of the phosphate of lime, from which their natural solidity is derived, or else of this matter not being duly secreted and deposited in their fabric. In rickets, the bones only yield and become distorted by slow degrees; but in the present disease they may be at once bent in any direction. The mollities ossium is rare, and its causes not well understood. All the cases of mollities ossium yet on record have proved fatal, and no means of cure are yet known. On dissection of those who have died, all the bones, except the teeth, have been found unusually soft, so that scarcely any of them could resist the knife, the periosteum has been found thicker than usual, and the bones have been found to contain a great quantity of oily matter and little earth.

Mala′ctica. (From *μαλασσω,* to soften.) Emollient medicines.

Malagfue′tta. Grains of paradise.

Malaguetta. Grains of paradise.

MALA'GMA. (From *μαλασσω*, to soften.) A poultice.

Malamiris. A species of *Piper*.

MALA'RIA. The name in Italy of an endemic intermittent, which attacks people in the neighbourhood of Rome, and especially about the Pontine marshes, which have often been drained to carry off the decomposing animal and vegetable materials that spread their *Aria cattiva*, as it is called, over the whole of the campagna.

Malarum ossa. See *Jugale os.*

MA'LATE. *Malas.* A salt formed by the union of the malic acid, or acid of apples with salifiable bases; thus *malate of copper*, *malate of lead*, &c.

Ma'le. The arm-pit.

Male fern. See *Polypodium filix mas.*

Male orchis. See *Orchis mascula.*

Male speedwell. See *Veronica officinalis.*

MALIC ACID. *Acidum malicum.* This acid is obtained by saturating the juice of apples with alkali, and pouring in the acetous solution of lead, until it occasions no more precipitate. The precipitate is then to be edulcorated, and sulphuric acid poured on it, until the liquor has acquired a fresh acid taste, without any mixture of sweetness. The whole is then to be filtered, to separate the sulphate of lead. The filtered liquor is the malic acid, which is very pure, remains always in a fluid state, and cannot be rendered concrete. See *Sorbic acid.*

MALIASMUS. (From *μαλις*, cutaneous vermination.) Breeding animalcules on the skin, as the louse, flea, tick, &c.

MALI'GNANT. (*Malignus*; from *malus*.) A term which may be applied to any disease, the symptoms of which are so aggravated as to threaten destruction of the patient. It is frequently used to signify a dangerous epidemic.

Malignant fever. See *Typhus.*

Malignant sore throat. See *Cynanche maligna.*

MA'LIS. (*Μαλις* and *μαλιασμος* are Greek nouns composing cutaneous vermination.) The name of a genus of diseases in Good's Nosology. Class, *Eccritica*; Order, *Acrotica.* Cutaneous vermination. It has six species, viz. *Malis pediculi*; *pulicis*; *acari*; *filariæ*; *œstri*; *gordii.*

MALLEABILITY. (*Malleabilitas*; from *malleus*, a hammer.) The property which several metals possess of being extended under the hammer into thin plates, without cracking. The thin leaves of silver and gold are the best examples of malleability. See *Ductility.*

Malleamothe. *Pavette*; *Pavate*; *Erysipelas curans arbor.* A shrub which grows in Malabar. The leaves, boiled in palm oil, cure the impetigo; the root, powdered and mixed with ginger, is diuretic.

MALLEATIO. A species of St. Vitus' dance, in which the person has a convulsive action of one or both hands which strike the knee like a hammer.

Mallei anterior. See *Laxator tympani.*

Mallei externus. See *Laxator tympani.*

Mallei internus. See *Tensor tympani.*

MALLE'OLUS. (Dim. of *malleus*, a mallet: so called from its supposed resemblance to a mallet.) The ancle, distinguished into external and internal, or *malleolus externus* and *internus.*

MA'LLEUS. (*Malleus quasi molleus*; from *mollio*, to soften; a hammer.) A bone of the internal ear is so termed from its resemblance. It is distinguished into a head, neck, and manubrium. The *head* is round, and encrusted with a thin cartilage, and annexed to another bone of the ear, the incus, by ginglymus. Its *neck* is narrow, and situated between the head and manubrium, or handle; from which a long slender process arises, adheres to a furrow in the auditory canal, and is continued as far as the fissure in the articular cavity of the temporal bone. The *manubrium* is terminated by an enlarged extremity, and connected to the membrana tympani by a short conoid process.

MALLOW. See *Malva.*

Mallow, round-leaved. See *Malva rotundifolia.*

Mallow, vervain. See *Malva alcea.*

Malograna'tum. (From *malum*, an apple, and *granum*, a grain: so named from its grain-like seeds.) The pomegranate.

MALPIGHI, Marcello, was born near Bologna, in 1628. He went through his preliminary studies with great eclat, and especially distinguished himself by his zealous pursuit of anatomy. His merit procured him, in 1653, the degree of doctor in medicine, and three years after, the appointment of professor of physic, at Bologna; but he was soon invited to Pisa, by the Grand Duke of Tuscany. However, the air of this place injuring his health, which was naturally delicate, he was obliged in 1659 to return to his office at Bologna. Three years after he was tempted by the magistrates of Messina to accept the medical professorship there; but his little deference to ancient authorities involved him in controversies with his colleagues, which forced him to return again to Bologna, in 1666. His reputation rapidly extended throughout Europe as a philosophical enquirer, and he was chosen a member of the Royal Society of London, which afterwards printed his works at their own expense. In 1691, Pope Innocent XII. on his election, chose Malpighi for his chief physician and chamberlain, when he removed to Rome; but three years after he was carried off by an apoplectic stroke. He joined with an indefatigable pursuit of knowledge, a remarkable degree of candour and modesty; and ranks very high among the philosophers of the physiological age in which he lived. He was the first to employ the microscope in examining the circulation of the blood; and the same instrument assisted him in exploring the minute structure of various organs, as is evident from his first publication on the lungs, in 1661; and this was followed by successive treatises on many other parts. In 1669, his essay "De Formatione Pulli in Ovo," was printed at London, with his remarks on the silkworm, and on the conglobate glands: much light was thrown by these investigations on the obscure subject of generation, and other important points of physiology. He was thence led to the consideration of the structure and functions of plants, and evinced himself an original, as well as a very profound observer. His "Anatome Plantarum" was published by the Royal Society in 1675 and 1679, with some observations on the incubation of the egg. His only medical work, "Consultatiorum Medicinalium Centuria Prima," did not appear till 1713: he was not distinguished as a practitioner, but deserves praise for pointing out the mischief of bleeding in the malignant epidemics, which prevailed in Italy in his time.

MALPI'GHIA. (So named in honour of Malpighi, the celebrated vegetable anatomist.) The name of a genus of plants in the Linnæan system. Class, *Decandria;* Order, *Trigynia.*

MALPIGHIA GLABRA. The systematic name of a tree which affords an esculent cherry.

MALT. Grain which has become sweet, from the conversion of its starch into sugar, by an incipient growth or germination articially induced, called malting.

MA′LTHA. (From μαλασσω, to soften.) *Malthacodes.* 1. A medicine softened and tempered with wax.

2. The name of the mineral tallow of Kirwan, which resembles wax, and is said to have been found on the coast of Finland.

MALTHA′CTICA. (From μαλθακιζω, to soften.) Emollient medicines.

MALTHEORUM. Common salt.

MA′LUM. 1. A disease.

2. An apple.

MALUM MORTUUM. A disease that appears in the form of a pustule, which soon forms a dry, brown, hard, and broad crust. It is seldom attended with pain, and remains fixed for a long time before it can be detached. It is mostly observed on the tibia and os coccygis, and sometimes the face.

MALUM PILARE. See *Plica.*

MA′LUS. See *Pyrus malus.*

MALUS INDICA. *Bilumbi biting-bing,* of Bontius. The *Malus indica—fructu pentagono* of Europeans. It is carefully cultivated in the gardens of the East Indies, where it flowers throughout the year. The juice of the root is cooling, and drank as a cure for fevers. The leaves boiled and made into a cataplasm with rice, are famed in all sorts of tumours, and the juice of the fruit is used in almost all external heats, dipping linen rags in it, and applying them to the parts. It is drank, mixed with arrack, to cure diarrhœas; and the dried leaves, mixed with betel leaves, and given in arrack, are said to promote delivery. The ripe fruit is eaten as a delicacy, and the unripe made into a pickle for the use of the table.

MA′LVA. (*Malva, quasi molva;* from *mollis,* soft: named from the softness of its leaves.) 1. The name of a genus of plants in the Linnæan system. Class, *Monodelphia;* Order, *Polyandria.*

2. The pharmacopœial name of the common mallow. See *Malva sylvestris.*

MALVA ALCEA. *Malva verbenaca.* The vervain mallow. This plant is distinguished from the common mallow, by its leaves being jagged, or cut in about the edges. It agrees in virtues with the other mallows, but it is the least mucilaginous of any. This, like to the other mallows, abounds with a mucilage, and is good for pectoral drinks.

MALVA ARBOREA. See *Alcea rosea.*

MALVA ROTUNDIFOLIA. Round-leaved mallow. The whole herb and root possess similar virtues to the common mallow. See *Malva sylvestris.*

MALVA SYLVESTRIS. The systematic name of the common mallow. *Malva vulgaris; Malva—caule erecto herbaceo, foliis septemlobatis acutis, pedunculis petiolisque pilosis.* This indigenous plant has a strong affinity to the althæa, both in a botanical and a medical respect. See *Althæa.* The leaves and flowers are principally used in fomentations, cataplasms, and emollient enemas. The internal use of the leaves seems to be wholly superseded by the radix althæa.

MALVA VERBENACA. See *Malva alcea.*

MALVA VULGARIS. See *Malva sylvestris.*

MALVAVI′SCUS. (From *malva,* the mallow, and *viscus,* glue: so named from its viscidity.) See *Althæa officinalis.*

MALVERN. The village of Great Malvern has, for many years, been celebrated for a spring of remarkable purity, which has acquired the name of the holy well, from the reputed sanctity of its waters, and the real and extensive benefit long derived in various cases from its use.

The holy well water, when first drawn, appears quite clear and pellucid, and does not become sensibly turbid on standing. It possesses somewhat of an agreeable pungency to the taste; but this is not considerable. In other respects it does not differ in taste from pure good water.

The contents of Malvern holy well are:—some carbonic acid, which is in an uncombined state, capable of acting upon iron, and of giving a little taste to the water; but the exact quantity of which has not been ascertained:—a very small portion of earth, either lime or magnesia, united with the carbonic and marine acids: perhaps a little neutral alkaline salt, and a very large proportion of water:—for we may add, that, the carbonic acid perhaps excepted, the foreign matter is less than that of any spring-water which we use. No iron or metal of any kind is found in it, though there are chalybeates in the neighbourhood.

It is singular that, notwithstanding its apparent purity, this water is said not to keep well, and soon acquires a fœtid smell, by standing in open vessels.

Malvern water, like many others, was at first only employed as an external application; and this, indeed, is still its principal use, though it is extended, with some advantage, to a few internal diseases. It has been found highly efficacious in painful and deep ulcerations, the consequence of a scrophulous habit of body, and which are always attended with much local irritation, and often general fever. Applied to the sore, it moderates the profuseness of the discharge, corrects the fœtor, which so peculiarly marks a caries of the bone, promotes the granulating process, and a salutary exfoliation of the carious part; and by a long perseverance in this course, very dangerous and obstinate cases have at last been cured. Inflammation of the eye, especially the ophthalmia, which is so troublesome in scrophulous habits, often yields to this simple application, and we find that, for a great number of years, persons afflicted with sore eyes have been in the habit of resorting to Malvern holy well. Another order of external diseases, for which this water is greatly celebrated, is cutaneous eruptions; even those obstinate cases of dry desquamations, that frequently follow a sudden application of cold in irritable habits, are often cured by this remedy. Where the skin is hot and dry, it remarkably relieves the intolerable itching of herpetic disorders, and renders the surface of the body more cool and perspirable. It appears, however, from a nice observation of Dr. Wall, that this method of treatment is not so successful in the cutaneous eruptions of very lax leucophlegmatic habits, where the extremities are cold and the circulation languid; but that it succeeds best where there is unusual irritation of the skin, and where it is apt to break in painful fissures, that ooze out a watery acrid lymph. On the first application of this water to an inflamed surface, it will often for a time increase the pain and irritation, but these effects go off in a few days.

The great benefit arising from using Malvern waters, as an external remedy, in diseases of the skin and surface of the body, has led to its employment in some internal disorders, and often with considerable advantage. Of these, the most important are painful affections of the kidneys and bladder, attended with the discharge of bloody, purulent, or fœtid urine, the hectic fever, produced by scrophulous ulceration of the lungs, or very extensive and irritating sores on the surface of the body, and also fistulas of long standing, that have been neglected, and have become constant and troublesome sores.

The Malvern water is in general a perfectly safe application, and may be used with the utmost freedom, both as an external dressing for sores, and as a common drink.

The internal use of Malvern waters is sometimes attended at first with a slight nausea, and not unfrequently, for the first day or two, it occasions some degree of drowsiness, vertigo, or slight pain of the head, which comes on a few minutes after drinking it. These symptoms go off spontaneously, after a few days, or may readily be removed by a mild purgative. The effects of this water on the bowels are not at all constant; frequently it purges briskly for a few days, but it is not uncommon for the body to be rendered costive by its use, especially, as Dr. Wall observes, with those who are accustomed to malt liquors. In all cases, it decidedly increases the flow of urine, and the general health of the patient. The duration of a course of Malvern waters must vary very considerably on account of the different kinds of disease for which this spring is resorted to.

Mame′i. The mammoe, momin, or toddy-tree. This tree is found in different parts of the West Indies, but those on the Island of Hispaniola are the best. From incisions made in the branches, a copious discharge of pellucid liquor is obtained, which is called momin, or toddy wine. It must be drank very sparingly, because of its very diuretic quality. It is esteemed as an effectual preservative from the stone, as also a solvent of it when generated. There are two species.

MAMI′LLA. (Diminutive of *mamma*, the breast.) 1. The breast of man.

2. The nipple of the male and female breasts.

Mami′ra. It is said, by Paulus Ægineta, to be the root of a plant which is of a detergent quality. Some think it is the root of the doronicum; but what it really is cannot be ascertained.

MA′MMA. See *Breast*.

MA′MMARY. Belonging to the breast.

Mammary artery. *Arteria mammillaris.* The internal mammary artery is a branch of the subclavian, and gives off the mediastinal, thymal, and pericardial arteries. The external mammary is a branch of the axillary artery.

Mammary vein. *Vena mamillaris.* These vessels accompany the arteries, and evacuate their blood into the subclavian vein.

MAMMEA. (So called from its vernacular appellation in the West Indies, *mamei*, and allowed by Linnæus, because of its affinity to *mamma*, a breast, alluding to the shape of its fruit.) The name of a genus of plants. Class, *Polyandria*; Order, *Monogynia*.

Mammea americana. The systematic name of a tree, which affords a delicious fruit called *mammea*. It has a very grateful flavour when ripe, and is much cultivated in Jamaica, where it is generally sold in the markets for one of the best fruits of the island.

MAN. *Homo*. Man is compounded of solids, fluids, a vital principle, and, what distinguishes him from every other animal, a soul. See *Animal*.

Ma′ncoron. According to Oribasius, a kind of sugar found in a sort of cane.

Mancura′na. See *Origanum vulgare*.

MANDI′BULA. (From *mando*, to chew.) The jaw. See *Maxilla inferior*.

MANDRA′GORA. (From μανδρα, a den, and αγειρω, to collect: because it grows about caves and dens of beasts; or from the German *mandragen*, bearing man.) See *Atropa mandragora*.

Mandragori′tes. (From μανδραγορα, the mandrake.) Wine, in which the roots of the male mandrake are infused.

MANDRAKE. See *Atropa mandragora*.

MANDUCA′TOR. (From *manduco*, to chew.) A muscle which assists in the action of chewing.

Ma′nga. (Indian.) The mango-tree.

MANGANESE. This metallic substance seems, after iron, to be the most frequently diffused metal through the earth; its ores are very common. As a peculiar metal, it was first noticed by Gahn and Scheele, in the years 1774 and 1777. It is always found in the state of an oxide, varying in the degree of oxidisement. La Peyrouse affirmed that he had found manganese in a metallic state; but there was probably some mistake in his observation. The ores are distinguished into *grey oxide of manganese*, *black oxide of manganese*, *reddish white oxide of manganese*, and *carbonate of manganese*. All these combinations have an earthy texture; they are very ponderous; they occur both amorphous and crystallised; and generally contain a large quantity of iron. Their colour is black, blackish-brown, or grey, seldom white. They soil the fingers like soot. They are sometimes crystallised in prisms, tetrahedral, rhomboidal, or striated.

Properties.—Manganese is of a whitish grey colour. Its fracture is granulated, irregular, and uneven. It is of a metallic brilliancy, which it, however, soon loses in the air. Its specific gravity is about 8. It is very hard and extremely brittle. It is one of the most refractory metals, and most difficult to fuse, requiring at least 160° of Wedgwood's pyrometer. Its attraction of oxygen is so rapid, that exposure to the air is sufficient to render it red, brown, black, and friable, in a very short time; it can therefore, only be kept under water, oil, or ardent spirit. It is the most combustible of all the metals. It decomposes water, by means of heat, very rapidly, as well as the greater part of the metallic oxides. It decomposes sulphuric acid. It is soluble in nitric acid. It is fusible with earths, and colours them brown, violet, or red, according to its state of oxidisement. It frees from colour glasses tinged by iron. It does not readily unite with sulphur. It combines with phosphorus. It unites with gold, silver, and copper, and renders them brittle. It unites to arsenic in close vessels, but does not enter into union with mercury.

Manganese, heated in oxygen or clorine, takes fire and forms an oxide or chloride. It has been thought difficult to decide on the oxides of manganese.

According to Sir H. Davy there are two oxides only, the olive and the black; Mr. Brande has three, the olive, dark red, and black; Thenard has four, the green, the white (in the state of hydrate,) the chesnut-brown, and the black; Berzelius has five, the first grey, the second green, the third and fourth are not well defined, and the fifth is the black.

Two oxides, however, are well defined.

1. The first oxide may be obtained by dissolving common black manganese in sulphuric or ni-

tric acid, adding a little sugar, and precipitating by solution of potassa. A white powder is obtained, which being heated to redness out of the contact of air, becomes yellow, puce-coloured, and, lastly, red-brown. To be preserved, it should be washed in boiling water, previously freed from air, and then dried by distilling off the moisture in a retort filled with hydrogen. The dark olive oxide, when examined in large quantities, appears almost black; but when spread upon white paper, its olive tint is apparent. It takes fire when gently heated, increases in weight, and acquires a browner tint. It slowly absorbs oxygen from the air, even at common temperatures. It dissolves in acids without effervescence. The white powder obtained above, is the hydrated protoxide. The different tints which it assumes by exposure to air, are supposed by Sir H. Davy to depend on the formation of variable quantities of the black-brown oxide, which probably retains the water contained in the white hydrate, and is hence deep puce-coloured.

2. The black *peroxide*. Its sp. gr. is 4. It does not combine with any of the acids. It yields oxygen when heated; and by intense ignition passes in a great measure into the protoxide.

Method of obtaining Manganese.—This metal is obtained by mixing the black oxide, finely powdered, with pitch; making it into a ball, and putting this into a crucible, with powdered charcoal, one-tenth of an inch thick at the sides, and one-fourth of an inch deep at the bottom. The empty space is then to be filled with powdered charcoal; a cover is to be luted on; and the crucible exposed, for an hour, to the strongest heat that can be raised. Or, digest the black oxide of manganese repeatedly, with the addition of one-sixteenth of sugar, in nitric acid; dilute the mixture with three times its bulk of water; filter it, and decompose it by the addition of potassa; collect the precipitate, form it into a paste with oil, and put it into a crucible, well lined with charcoal. Expose the crucible for at least two hours to the strongest heat of a forge.

MANGANESIC ACID. (*Acidum manganesium;* from *manganese*, its base.) Chevillot and Edwards have ascertained that the carnelion mineral which is formed by igniting a mixture of the black oxide of manganese and nitre, has the property of making a neutral manganesate of potassa.

Mangel wursel. The root of scarcity. The *Beta hybrida* of Linnæus. A plant of great importance, as a substitute for bread in periods of famine. It is cultivated here as green food for cattle, especially milch cows. It has not however succeeded so well in this country as in Germany.

MANGET, John James, was born at Geneva in 1652. He originally studied for the clerical profession, but, after five years' labour, his inclination to medical pursuits prevailed, and he made such progress, without the aid of any teacher, that he was admitted to the degree of doctor at Valence in 1678. He then commenced practice in his native city, and obtained considerable reputation, and refused many invitations to go to other countries. In 1699 he was appointed chief physician to Frederick III. afterwards first King of Prussia. In his literary labours he was indefatigable even to the end of his life, which terminated in his 91st year. Among the numerous works of compilation, executed by him, originality is not to be expected; nor are they remarkable for judgment or accuracy, though still sometimes useful for reference. He published ample collections on almost every subject connected with medicine, besides improved editions of the works of others: but the most important of his productions is entitled, "Bibliotheca Scriptorum Medicorum veterum et recentiorum," at which he laboured when at least eighty years of age.

MANGI'FERA. (From *mango*, the name of the fruit which it bears.) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia.* The Mango-tree.

Mangifera indica. The systematic name of the mango-tree, which is cultivated all over Asia. Mangoes, when ripe, are juicy, of a good flavour, and so fragrant as to perfume the air to a considerable distance. They are eaten either raw or preserved with sugar. Their taste is so luscious, that they soon pall the appetite. The unripe fruits are pickled in the milk of the cocoa-nut, that has stood until sour, with salt, capsicum, and garlick. From the expressed juice is prepared a wine; and the remainder of the kernel can be reduced to an excellent flour for the making of bread.

MANGO. See *Mangifera indica.*

Mangostana. See *Garcinia mangostana.*

Mangosteen. See *Garcinia mangostana.*

MA'NIA. (From μαινομαι, to rage.) Raving or furious madness. A genus of disease in the class *Neuroses;* and order *Vesaniæ*, of Cullen. The definition of mania is delirium, unaccompanied with fever; but this does not seem altogether correct, as a delirium may prevail without any frequency of pulse or fever; as happens sometimes with women in the hysteric disease. In mania, the mind is not perfectly master of all its functions; it receives impressions from the senses, which are very different from those produced in health; the judgment and memory are both lost, or impaired, and the irritability of the body is much diminished, being capable, as is supposed, of resisting the usual morbid effects of cold, hunger, and watching, and being likewise less susceptible of other diseases than before.

Mania may be said to be a false perception of things, marked by an incoherence, or raving, and a resistance of the passions to the command of the will, accompanied, for the most part, with a violence of action, and furious resentment at restraint.

There are two species of madness, viz. the melancholic and furious.

Madness is occasioned by affections of the mind, such as anxiety, grief, love, religion, terror, or enthusiasm; the frequent and uncurbed indulgence in any passion, or emotions, and by abstruse study. In short, it may be produced by any thing that affects the mind so forcibly as to take off its attention from all other affairs. Violent exercise, frequent intoxication, a sedentary life, the suppression of periodical and occasional discharges and secretions, excessive evacuations, and paralytic seizures, are likewise enumerated as remote causes. Certain diseases of the febrile kind have been found to occasion madness, where their action has been very violent. In some cases it proceeds from an hereditary predisposition. Two constitutions are particularly the victims of madness; the sanguine and melancholic: by the difference of which its appearance is somewhat modified. Each species of mania is accompanied with particular symptoms. Those which attend on the melancholic are sadness, dejection of spirits, and its attendants. Those which accompany an attack of furious madness, are severe pains in the head, redness of the face, noise in the ears, wildness of the countenance, rolling and glistening of the eyes, grinding of the teeth, loud roaring, violent exertion of strength, absurd incoherent discourse, unaccountable malice to certain persons, particularly to the nearest relatives and friends, a dislike to such places and scenes as formerly afforded particular pleasure, a diminution of the irritability of the body, with respect to the morbid effects of cold, hunger, and watching, together with a full, quick pulse.

Mania comes on at different periods of life; but, in the greater number of cases, it makes its attack between thirty and forty years of age. Females appear to be more subject to mania than males.

Dissections of maniacal cases, Dr. Thomas observes, most generally show an effusion of water into the cavities of the brain; but in some cases, we are able to discover evident marks of previous inflammation, such as thickening and opacity of the tunica arachnoides and pia mater. In a few instances, a preternatural hardness of the substance of the brain.

From Dr. Greding's observations, it appears that the skulls of the greater number of such persons are commonly very thick. Some he found of a most extraordinary degree of thickness; but it appears that the greater number of insane people die of atrophy and hydrothorax.

The treatment of madness is partly corporeal, partly mental. The leading indications under the first head are: to diminish vascular or nervous excitement when excessive, as in mania; to increase them when defective, as in melancholia; at the same time guarding against the several exciting causes, and removing any obvious fault in the constitution, or in particular parts, by which the brain may be sympathetically affected. Among the most powerful means of lessening excitement is the abstraction of blood, which freely practised has been often an effectual remedy in recent cases and robust habits; but repeated small bleedings are rather likely to confirm the disease; and in those, who have long laboured under it, the object should merely be to obviate dangerous accumulation in the head, by occasionally withdrawing the requisite quantity locally. Purging is much more extensively applicable: where the strength will admit, it may be useful to make very large evacuations in this way; and in all cases it should be a rule to procure regular discharges from the bowels, which are generally torpid. Calomel is mostly proper, as it may evacuate bile more freely, and have other beneficial effects; but it usually requires the assistance of other cathartics. The application of cold to the head is materially serviceable under increased excitement, and some have advised it to the body generally; at any rate, the accumulation of heat should be avoided, and the antiphlogistic regimen steadily observed. Emetics have sometimes had a good effect, especially as influencing the mind of the patient; but to diminish excitement, and induce diaphoresis, it will generally be better to give merely nauseating doses; and occasionally their operation may be promoted by the tepid bath; even the hot bath has been found useful, producing great relaxation, and rendering the patient more tractable. Digitalis may be employed with advantage from its sedative power, exerted especially on the circulation, pushing it till some obvious effect is produced. Narcotics, particularly opium, have been much used, but certainly are not indiscriminately proper; where there is fulness of the vessels of the head, they may even do mischief; and where organic disease exists, they will probably only palliate: whenever resorted to, the dose should be large, such as may induce sleep, and if no mitigation of the disease appear, it may be better not to persevere in them. Camphor has been sometimes decidedly useful, carried gradually to a very considerable extent. Blisters and other means of lessening fulness and irritation in the brain, should not be neglected, where circumstances indicate their use.—In the melancholic, on the other hand, where there is rather a deficiency of excitement, it is necessary to direct a more generous diet, nutritious and easy of digestion, as the stomach is usually weak, with a moderate quantity of some fermented liquor, and medicines of a tonic or even stimulant nature, especially ammonia, to relieve flatulence and acidity. Attention should be paid to the bowels, and to maintain the function of the skin, &c. The utility of the cold bath seems questionable in melancholics; though it may occasionally arrest a paroxysm of mania. Regular exercise may contribute materially to improve the health; and even hard labour has been often signally useful in a convalescent state, particularly to those accustomed to it. If the mental derangement supervened on the stoppage of any evacuation, or the metastasis of any other disorder; or appear connected with a scrophulous or syphilitic taint; proper remedies to restore the former, or remove the latter, should be exhibited: and in some instances trepanning has relieved the brain from local irritation. In the management of the insane, it is necessary to inspire a certain degree of awe from a conviction of superior power, and at the same time seek to gain their confidence and affection by steadiness and humanity. Some restraint is often necessary for the security of the patient, or of others, carefully watching, or even confining them, if they threaten the lives of their attendants. When they refuse to take food, or medicine, or any thing which appears absolutely necessary, coercion is proper, or sometimes these caprices may be overcome by stratagem; or exciting uneasy sensations by the motion of a swing, whirling chair, &c. In order to remove any deranged association of ideas, it will be right to endeavour to occupy their minds with some agreeable and regular train of thought, cheerful music, poetry, narrative, the elementary parts of geometry, &c. according to their previous inclinations; to lead them gradually to their former habits, and the society of their friends, engage them in rural sports, take them to public amusements, the watering places, &c. but with as little appearance of design as possible.

MANIGUETTA. See *Amomum granum Paradisi.*

MA'NIHOT. See *Jatropha manihot.*

MANI'PULUS. (*Quod manum impleat*, because it fills the hand.) A handful.

MANJAPU'MERAM. A common tree in the West Indies, the flowers of which are distilled, and the water used against inflammations of the eyes.

MA'NNA. (From *mano*, a gift, Syrian; it being the food given by God to the children of Israel in the wilderness: or from *mahna*, what is it? an exclamation occasioned by their wonder at its appearance.) See *Fraxinus ornus.*

MANNA BRIGANTIACA. A species of manna brought from the neighbourhood of Brianconois, in Dauphiny.

MANNA CALABRINA. Calabrian manna.

MANNA CANULATA. Flaky manna, or manna concreted on straw, or chips.

MANNA THURIS. A coarse powder of olibanum.

MANNIFERA ARBOR. (From *manna*, and *fero*, to bear.) See *Fraxinus ornus.*

MANSO'RIUS. (From *mando*, to chew.) The masseter muscle.

Manti'le. The name of a bandage.

MANUS. The hand. This consists of the carpus, metacarpus, and fingers.

Ma'nus dei. 1. A name of a resolvent plaster, described by Lemery.

2. An old name of opium.

MAPLE. See *Acer pseudoplatanus.*

Mara'nda. A species of myrtle, growing in the island of Ceylon, a decoction of the leaves of which is said to be excellent against the venereal disease.

MARA'NTA. 1. The name of a genus of plants in the Linnæan system. Class, *Monandria;* Order, *Monogynia.*

2. The name of the Indian arrow-root of which there are three species, the *Arundinacea, Galanga,* and *Comesa,* all of them herbaceous, perennial exotics of the Indies, kept here in hot-houses for curiosity; they have thick, knotty, creeping roots, crowned with long, broad, arundinaceous leaves, ending in points, and upright stalks half a yard high, terminated by bunches of monopetalous, ringent, five-parted flowers. They are propagated by parting the roots in spring, and planting them in pots of light rich earth, and then plunging them in the bark-bed.

Maranta arundinacea. The root of this species, commonly called arrow-root, is used by the Indians to extract the virus communicated by their poisoned arrows, from whence it has obtained its name. It is cultivated in gardens and provision-grounds in the West Indies; and the starch is obtained from it by the following process:—The roots, when a year old, are dug up, well washed in water, and then beaten in a large deep wooden mortar, to a pulp; this is thrown into a large tub of clean water: the whole is then well stirred, and the fibrous part rung out by the hands, and thrown away. The milky liquor being passed through a hair sieve, or coarse cloth, is suffered to settle, and the clear water drained off. At the bottom of the vessel is a white mass, which is again mixed with clean water, and drained: lastly, the mass is dried on sheets in the sun, and is pure starch.

Arrow-root contains, in small bulk, a greater proportion of nourishment than any other yet known. The powder, boiled in water, forms a very pleasant transparent jelly, very superior to that of sago or tapioca, and is much recommended as a nutritious diet for children and invalids. The jelly is made in the following manner—to a dessert-spoonful of powder, add as much cold water as will make it into a paste; then pour on half a pint of boiling water: stir it briskly, and boil it a few minutes, when it will become a clear smooth jelly; a little sugar and sherry wine may be added for debilitated patients, but for infants a drop or two of essence of caraway-seeds or cinnamon, is preferable, wine being very liable to become acescent in the stomachs of infants, and thus disagree with the bowels. Fresh milk, either alone or diluted with water may be substituted for the water. For very debilitated frames, and especially for ricketty children, this jelly blended with an animal jelly, as that of the stag's horn (*rasuræ cornu cervi,*) affords a more nutritious diet than arrow-root alone, which may be done in the following manner:—Boil half an ounce of stag's horn shavings, in a pint of water, for fifteen minutes; then strain and add two dessert-spoonsful of arrow-root powder, previously well-mixed with a tea-cupful of water; stir them briskly together, and boil them for a few minutes. If the child should be much troubled with flatulency, two or three drops of essence of caraway-seeds, or a little grated nutmeg may be added; but for adults, port wine, or brandy, will answer best.

Maranta galanga. The smaller galangal. The roots of this plant are used medicinally; two kinds of galangal are mentioned in the pharmacopœias; the greater galangal obtained from the *Kæmpferia galanga* of Linnæus, and the smaller galangal, the root of the *Maranta galanga; caulino simplici foliis lanceolatis subsessilibus* of Linnæus. The dried root is brought from China, in pieces from an inch to two in length, scarcely half so thick, branched, full of knots and joints, with several circular rings of a reddish-brown colour on the outside, and brownish within. It has an aromatic smell, not very grateful, and an unpleasant, bitterish, hot, biting taste. It was formerly much used as a warm stomachic bitter, and generally ordered in bitter infusions. It is now, however, seldom employed.

MARA'SMUS. (From μαραινω, to grow lean.) Emaciation. 1. A wasting away of the flesh, without fever or apparent disease. See *Atrophia.*

2. The name of a genus of diseases in Good's Nosology. Class, *Hemætica;* Order, *Dysthetica.* Emaciation. It embraces four species, viz. *Marasmus atrophia, climactericus, tabes, phthisis.*

Marathri'tes. (From μαραθρον, fennel.) A vinous infusion of fennel; or wine impregnated with fennel.

MARATHROPHY'LLUM. (From μαραθρον, fennel, and φυλλον, a leaf: so named because its leaves resemble those of the common fennel.) See *Peucedanum officinale.*

Mara'thrum. (From μαραινω, to wither: so called because its stalk and flowers wither in the autumn.) See *Anethum fœniculum.*

Marathrum sylvestre. See *Peucedanum officinale.*

MARBLE. A species of limestone or carbonate of lime. Powdered marble is used, in pneumatic medicine, to give out carbonic acid gas.

MARCASITE. See *Bismuth.*

MARCESCENS. Withering, decaying: applied to the perianths of the *Pyrus communis,* and *Mespilus germanica.*

MARCHANTIA. (Named after Marchant, who wrote several Essays on the Memoirs of the Academy of Science, 1713.) The name of a genus of plants. Class, *Cryptogamia;* Order, *Algæ.*

Marchantia polymorpha. The systematic name of the liver-wort. *Hepatica terrestris; Jecoraria.* A plant very common in this country. It has a penetrating though mild pungency, and bitter taste, sinking, as it were, into the tongue. It is recommended as an aperient, resolvent, and antiscorbutic, and though seldom used in this country, appears to be a plant of no inconsiderable virtue.

MARCO'RES. (*Marcores,* pl. of *marcor;* from *marceo,* to become lean.) Universal emaciation. The first order in the class *Cachexiæ,* of Cullen's Nosology.

MARESTAIL. See *Hippuris vulgaris.*

MARGARI'TA. (From *margalith,* Rab.) The pearl. 1. The pearl. *Perla; Unio.* A small, calcareous concretion, of a bright transparent whiteness, found on the inside of the shell, *Concha margaritifera* of Linnæus, or mother-of-pearl fish. Pearls are very highly prized. They consist of alternating concentric layers of membrane and carbonate of lime. They were formerly exhibited as antacids.

2. A tumour upon the eye resembling a pearl.

MARGARITIC ACID. (*Acidum margariticum; from margarita*, the pearl: so called from its pearly appearance.) Margaric acid. When we immerse soap made of pork-grease and potassa in a large quantity of water, one part is dissolved, while another part is precipitated in the form of several brilliant pellets. These are separated, dried, washed in a large quantity of water, and then dried on a filter. They are now dissolved in boiling alkohol, sp. gr. 0.820, from which, as it cools, the pearly substance falls down pure. On acting on this with dilute muriatic acid, a substance of a peculiar kind, which Chevreuil, the discoverer, calls margarine, or margaric acid, is separated. It must be well washed with water, dissolved in boiling alkohol, from which it is recovered in the same crystalline pearly form, when the solution cools.

Margaric acid is pearly white, and tasteless. Its smell is feeble, and a little similar to that of melted wax. Its specific gravity is inferior to water. It melts at 134° F. into a very limpid, colourless liquid, which crystallises on cooling, into brilliant needles of the finest white. It is insoluble in water, but very soluble in alkohol, sp. gr. 0.800. Cold margaric acid has no action on the colour of litmus; but when heated so as to soften without melting, the blue was reddened. It combines with the salifiable bases, and forms neutral compounds. Two orders of margarates are formed, the *margarates* and the *supermargarates*, the former being converted into the latter, by pouring a large quantity of water on them. Other fats besides that of the hog yield this substance.

That of man is obtained under three different forms. 1. In very fine long needles, disposed in flat stars. 2. In very fine and very short needles, forming waved figures, like those of the margaric acid of carcases. 3. In very large brilliant crystals disposed in stars, similar to the margaric acid of the hog. The margaric acids of man and the hog resemble each other; as do those of the ox and the sheep; and of the goose and the jaguar. The compounds with the bases, are real soaps. The solution in alkohol affords the transparent soap of this country.

MARIGOLD. See *Calendula officinalis.*

Marigold, marsh. See *Caltha palustris.*

MARINE. (*Marinus*; from *mare*, the sea.) Appertaining to the sea.

Marine acid. See *Muriatic acid.*

Marine salt. See *Sodæ murias.*

Marife'ndam. A plant in the island of St. Domingo: a distilled water from the tops is held in great esteem against pains in the stomach.

MARI'SCA. An excrescence about the anus, or the piles in a state of tumefaction.

Mari'sicum. The *Mercurialus fruticosa.*

MARJORAM. See *Origanum.*

MARJORA'NA. See *Origanum.*

MARLE. See *Limestone.*

MARMALADE. The pulp of quinces, or any other fruit, boiled into a consistence with honey.

Marmary'gæ. (From μαρμαιρω, to shine.) An appearance of sparks, or coruscations, flashing before the eyes.

Marmola'ria. (From *marmor*, marble: so named because it is spotted like marble.) See *Acanthus mollis.*

MARMOR. Marble.

Marmor metalicum. Native sulphate of barytes.

Marmora'ta aurium. (From *marmor*, marble.) The wax of the ear.

Marmo'reus tartarus. The hardest species of *human calculus.*

Marmorigr. An affection of the eyes, in which sparks and flashes of fire are supposed to present themselves.

Maroco'stinum. A purgative extract made of the marum and costus; originally made by Mindererus.

MARROW. *Medulla.* The fat substance secreted by the small arteries of its proper membrane; and contained in the medullary cavities of the long cylindrical bones. See *Bone.*

Marrow, spinal. See *Medulla spinalis.*

Marrubia'strum. The *Balote nigra*, or stinking horehound.

MARRUBIUM. (From *marrob*, a bitter juice, Heb.) Horehound. 1. The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Gymnospermia.*

2. The pharmacopœial name of the common horehound. See *Marrubium vulgare.*

Marrubium album. See *Marrubium vulgare.*

Marrubium alysson. *Alyssum.* Galen's madwort. It is supposed to be diaphoretic.

Marrubium aquaticum. Water horehound; opening, corroborant.

Marrubium hispanicum, or Spanish horehound. See *Marrubium verticillatum.*

Marrubium nigrum fœtidum. The black, stinking horehound, or *Balote nigra.*

Marrubium verticillatum. *Marrubium hispanicum.* The *Sideritis syriaca*, or base horehound.

Marrubium vulgare. The systematic name of the common horehound. *Marrubium album; Marrubium—dentibus calycinis, setaceis uncinatis* of Linnæus. The leaves of this indigenous plant have a moderately strong smell of the aromatic kind, but not agreeable; which, by drying, is improved; and in keeping for some months is, in great part, dissipated; their taste is very bitter, penetrating, diffusive, and durable in the mouth. That horehound possesses some share of medicinal power, may be inferred from its sensible qualities; but its virtues do not appear to be clearly ascertained. It is a favourite remedy with the common people in coughs and asthmas. The usual dose is from half an ounce to an ounce, in infusion, two or three times a-day. The dose of the extract is from gr. x. to ℥ss.

MARS. The mythological and alchemistical name of iron.

Mars alkalizatus. One of the alkalies with an admixture of iron.

Mars saccharatus. Iron mixed with starch and melted sugar.

Mars solubilis. Ferrum tartarizatum.

Mars sulphuratus. Iron filings, and sulphur deflagrated.

Marseilles hart-wort. See *Seseli tortuosum.*

Marsh-mallow. See *Althæa officinalis.*

Marsh trefoil. See *Menyanthes trifoliata.*

MARSUPIA'LIS. (From *marsupium*, a purse: so named from its resemblance.) See *Obturatur internus.*

Martagon lily. See *Lilium martagon.*

MARTIAL. (*Martialis*; from *Mars*, iron.) Sometimes used to express preparations of iron, or such as are impregnated therewith; as the *Martial Regulus* of antimony, &c.

Martial ethiops. The protoxyde of iron.

Martial salts. Salts of iron.

Martia'tum unguentum. Soldiers' ointment. Ointment of laurel, rue, marjoram, &c.

MA'RTIS LIMATURA PRÆPARATA. Purified filings of iron.

MARTYN, JOHN, was born in 1699. His father, being in a mercantile station in London, he was intended to succeed in this, which he does not appear to have neglected; but his taste for literature led him to devote much of the night to study. His partiality, however, was particularly directed to botany, and he made many experiments on the germination of seeds, &c. When about 22 years of age, he became secretary of a botanical society, and proved one of its most active members: three years after, he was admitted into the Royal Society, and many of his papers appeared in the Philosophical Transactions, of which he subsequently took a part in the Abridgment. At what period he changed to the medical profession is not known. In 1726, he published his tables of officinal plants, disposed according to Ray's system. Having given public lectures on botany in London with much approbation, he was thought qualified to teach that science at Cambridge; and accordingly, in the following year, he delivered the first course ever heard in that university. In 1730, he entered at Emanuel college, with an intention of graduating in physic; but this was soon abandoned on his marriage, and from the necessary attendance to his profession in London. On the death of the botanical professor at Cambridge, Mr. Martyn was appointed to succeed him in the beginning of 1733; but he continued lecturing only two or three years, owing to the want of sufficient encouragement, and especially of a botanic garden there. In 1741, he published a splendid quarto edition of Virgil's Georgics, in which much new light was thrown on the natural history of that author. Dr. Halley having assisted him in the astronomical part; this was followed by the Bucolics, on the same plan. In 1752, he retired from practice, and about nine years after resigned his professorship in favour of his son, the Rev. Thomas Martyn; in consequence of whose election he presented his botanical library, of above 200 volumes, with his drawings, herbarium, &c. to the university. He died in 1768.

MA'RUM. (From *mar*, Hebrew for bitter: so named from its taste.) Several species of teucrium were so named.

MARUM CRETICUM. See *Teucrium marum.*

MARUM SYRIACUM. (From *mar*, bitter, Hebrew.) See *Teucrium marum.*

MARUM VERUM. See *Teucrium marum.*

MARUM VULGARE. See *Thymus mastichina.*

MA'RVISUM. Malmsey wine.

MA'SCHALE. Μασχαλη. The arm-pit.

MASCHALI'STER. (From μασχαλιϛηρ.) The second vertebra of the back.

MASCULUS. There are two sexes of animals and vegetables, the male and the female. The male of animals is distinguished by his peculiar genital organs, and the analogy is carried to vegetables. A flower is called a male flower, which has stamina only, which are reckoned by the sexualists to be the male organ.

MA'SLACH. A medicine of the opiate kind, in use among the Turks.

MASPETUM. The leaf of the asafœtida plant.

MA'SSA. (From μασσω, to blend together.) A mass. A term generally applied to the compound out of which pills are to be formed.

MASSA CARNEA JACOBI SYLVII. See *Flexor longus digitorum pedis.*

MA'SSALIS. An old name for mercury.

MASSE'TER. (From μασσαομαι, to chew; because it assists in chewing.) *Zigomato-maxillaire*, of Dumas. A muscle of the lower jaw, situated on the side of the face. It is a short, thick muscle, which arises, by fleshy and tendinous fibres, from the lower edge of the malar process of the maxillary bone, the lower horizontal edge of the os malæ, and the lower edge of the zygomatic process of the temporal bone, as far backwards as the eminence belonging to the articulation of the lower jaw. From some little interruption in the fibres of this muscle, at their origin, some writers describe it as arising by two, and others by three distinct portions, or heads. The two layers of fibres of which it seems to be composed, cross each other as they descend, the external layer extending backwards, and the internal one slanting forwards. It is inserted into the basis of the coronoid process, and into all that part of the lower jaw which supports the coronoid and condyloid processes. Its use is to raise the lower jaw, and, by means of the above-mentioned decussation, to move it a little forwards and backwards in the act of chewing.

MASSICOT. The yellow oxide of lead.

MA'SSOY CORTEX. See *Cortex massoy.*

MASTERWORT. See *Imperatoria.*

MASTIC. See *Pistachia lentiscus.*

MASTICATION. (*Masticatio*; from *mastico*, to chew.) Chewing. A natural function. It embraces the seizing, catching, or taking the food, the chewing and the insalivation. The organs for taking in food are the superior extremities and the mouth.

The mouth is the oval cavity formed above, by the palate and the upper jaw; below, by the tongue and the lower jaw; on the sides, by the cheeks; behind, by the *velum* of the palate and the pharynx; and in front by the lips.

The dimensions of the mouth are variable in different persons, and are susceptible of an enlargement in every direction; downwards, by lowering the tongue and separating the jaws; transversely, by the distension of the cheeks, and from the front backward, by the motion of the lips, and of the *velum* of the palate.

The jaws determine most particularly the form and dimensions of the mouth; the superior jaw makes an essential part of the face, and moves only along with the head; on the contrary, the inferior possesses a very great mobility.

The jaws are furnished with small, very hard bodies, called teeth.

The edge of the socket is covered with a thick layer, fibrous, resisting, denominated gum.

We ought to consider in the parts that contribute to the apprehension of aliments, the muscles that move the jaws, and particularly the inferior. The same thing takes place with the tongue, the numerous motions of which have a great influence on the dimensions of the mouth.

Mechanism of the taking of food.—Nothing is simpler than the taking in of aliments: it consists in the introduction of alimentary substances into the mouth. For this purpose the hands seize the aliments and divide them into small portions susceptible of being contained in the mouth, and introduce them into it either directly or by means of proper instruments.

But, in order to their being received into this cavity, the jaws must separate; in other words, the mouth opens.

In many cases, when the food is introduced into the mouth, the jaws come together to retain it, and assist in mastication, or deglutition; but frequently the elevation of the inferior jaw contributes to the taking of the food. We have an example of it when one bites into fruit: then the incisors are thrust into the alimentary substance in opposite directions, and, acting as the blades of scissors, they detach a portion of the mass.

This motion is produced, principally by the contraction of the elevated muscles of the lower jaw, which represents a lever of the third kind, the *power* of which is at the insertion of the elevating muscles, the *point of support* at the articulation temporo-maxillary, and the resistance in the substance upon which the teeth act. The volume of the body placed between the incisors has an influence upon the force by which it may be pressed. If it is small the power will be much greater, for all the elevating muscles are inserted perpendicularly to the jaw, and the whole of their force is employed in moving the lever that it represents; if the volume of the body is such that it can hardly enter the mouth, though it presents very little resistance, the incisors will not enter it, for the *masseter*, the temporal, and the internal *pterygoid* muscles, are inserted very obliquely into the jaw, whence results the loss of the greater part of the force that they develope in contracting. When the efforts of the muscles of the jaws are not sufficient to detach a portion of the alimentary mass, the hand so acts upon it as to separate it from the portion retained by the teeth. On the other hand, the posterior muscles of the neck draw the head strongly back, and from the combination of these efforts results the separation of a portion of the food which remains in the mouth. In this mode the incisors and eye teeth are generally employed; the grinders are rarely used. By the succession of these motions of taking food the mouth is filled, and on account of the suppleness of the cheeks, and the easy depression of the tongue, a considerable quantity of food may be accumulated in it.

When the mouth is full, the *velum* of the palate is lowered, its inferior edge is applied upon the most distant part of the base of the tongue, so that all communication is intercepted between the mouth and the pharynx.

Independently of what we have said of the mouth, in respect to taking the food, to conceive its uses in mastication and insalivation, it is useful to remark that fluids abound in the mouth proceeding from different sources. First, the mucous membrane which covers its sides secretes an abundant mucosity; numerous isolated, or agglomerated follicles that are observed in the interior of the cheeks, at the junction of the lips with the gums, upon the back of the tongue, on the anterior aspect of the *velum* and the uvula, pour continually the liquid that they form into the internal surface of the mouth. The same thing takes place with mucous glands, which exist in great number in the interior of the cheeks and palate.

Lastly, there is poured into the mouth, the saliva secreted by six glands, three on each side, and which bear the name of *parotid sub-maxillary*, and *sub-lingual*. The first, placed between the external ear and the jaw, have each a secreting canal which opens on the level of the second small superior grinder; each maxillary gland has one which terminates on the sides of the ligaments of the tongue, near which those of the sub-lingual glands open.

These fluids are probably variable in their physical and chemical properties according to the organs by which they are formed; but the distinction has not yet been established by chemistry by direct experiments; the mixture under the name of saliva has been exactly analysed.

Among the alimentary substances deposited in the mouth, the one sort only traverse this cavity without suffering any change; the others, on the contrary, remain a considerable time in it, and undergo important modifications.

The first are the soft sorts of food, or nearly liquid, of which the temperature is little different from that of the body; the second are the aliments, which are hard, dry, fibrous, and those whose temperature is more or less different from what is proper for the animal economy. They are both in common, however, appreciated by the organs of taste in passing through the mouth.

We may attribute to three principal modifications the changes that the food undergoes in the mouth: 1st, change of temperature; 2d, mixture with the fluids that are poured into the mouth, and sometimes dissolution in these fluids; 3d, pressure more or less strong, and very often division, which bruising destroys the cohesion of their parts. It is besides, easily and frequently transported from one part of this cavity to another. These three modes of change do not take place successively, but simultaneously, by mutually favouring each other.

The change of temperature of the food retained in the mouth is evident; the sensation which it excites in it is sufficient to prove this. If it has a low temperature, it produces a vivid impression of cold, which continues until it has absorbed the caloric necessary to bring it near to the temperature of the sides of the mouth; the contrary takes place if the temperature is higher than that of the mouth.

It is the same with our judgment on this occasion, as with that which relates to the temperature of bodies which touch the skin: we join to it, unknown to us, a comparison with the temperature of the atmosphere and with that of the bodies which have been previously in contact with the mouth; so that a body preserving the same degree of heat will appear to us alternately hot or cold, according to the temperature of the bodies formerly in the mouth.

The change of temperature that the food undergoes in the mouth is only an accessary phenomenon; its trituration and its mixture more or less intimate with the fluids poured into this cavity, are what merit particular attention.

As soon as an aliment is introduced into the mouth, it is pressed by the tongue, applying it against the palate, or against some other part of the sides of the mouth. If the aliment is soft, if its parts cohere but little, this simple pressure is enough to break it; if the alimentary substance is composed of liquid and solid, the liquid is expressed by this pressure, and the solid part only remains in the mouth. The tongue produces the effect, of which we speak, so much better in proportion as its membrane is muscular, and as a great number of muscles are destined to move it.

It might astonish us that the tongue which is so soft could be capable of breaking a body offering even small resistance; but on the one hand, it hardens in contracting, like all the muscles, and, besides, it presents under the mucous membrane which covers its superior aspect, a dense and thick fibrous layer.

Such are the phenomena that take place if the food has but little resistance; but if it presents a considerable resistance, it then undergoes the action of the masticating organs.

The essential agents of mastication are the muscles that move the jaws, the tongue, the cheeks, and the lips: the *maxillary* bones and the teeth serve only as simple instruments.

Though the motions of both jaws may contribute to mastication, it is produced almost always by those of the inferior one. This bone may be lowered, raised, and pressed strongly against the upper jaw; carried forward, backward, and even directed a little towards the sides. These different motions are produced by the numerous muscles which are attached to the jaw.

But the jaws could never have produced the necessary effect in mastication if they had not been furnished with teeth, the physical properties of which are particularly suited to this digestive action.

Mechanism of mastication.—For the commencement of mastication, the inferior jaw must be lowered, an effect which is produced by the relaxation of its elevating, and the contraction of its depressing muscles. The food must then be placed between the dental arches, either by the tongue or some other agent; the inferior jaw is then raised by the masseter, internal pterygoid, and temporal muscles, the intensity of whose contraction depends upon the resistance of the food. This being pressed between two unequal surfaces whose asperities fit into each other, is divided into small portions, the number of which is in proportion to the facility with which they have given way.

But a motion of this kind reaches only a part of the food contained in the mouth, and it must be all equally divided. This takes place by the successive motions of the inferior jaw, and by the contraction of the muscles of the cheeks, of those of the tongue and lips, which bring the food between the teeth successively and promptly during the separation of the jaws, that it may be bruised when they come together.

When the alimentary substances are soft and easily bruised, two or three masticatory motions are sufficient to divide all that is in the mouth; the three kinds of teeth are employed in it. A longer continued mastication is necessary when the substances are more resisting, fibrous, or tough: in this case we chew only with the *molares*, and often only with one side at a time, to allow the other to rest. In employing the grinders there is an advantage of shortening the arm of the lever represented by the jaw, and by so doing of rendering it more advantageous for the power that moves it.

In the mastication, the teeth have sometimes to support very considerable efforts, which would inevitably shake, or else displace them, were it not for the extreme solidity of their articulation with the jaws. Each root acts like a wedge, in transmitting to the sides of the sockets the force by which it is pressed.

The advantage of the conical form of the roots is not doubtful. By reason of this form, the force by which the tooth is pressed, and which tends to thrust it into the jaw, is decomposed; one part tends to separate the sides of the sockets, the other to lower them; and the transmission, instead of being carried to the extremity of the root, which could not have failed to take place in a cylindric form, is distributed over all the surface of the socket. The grinders that have more considerable efforts to sustain, have a number of roots, or at least one very large. The incisors and eye teeth, that have only one small root, have never any great pressure to support.

If the gums had not presented a smooth surface and a dense tissue, placed as they are round the neck of the teeth and filling their intervals, they would have been torn every instant; for, in the mastication of hard and irregular substances, they are constantly exposed to the pressure of their edges and angles. This inconvenience happens whenever their tissue becomes soft, as in scorbutic affections.

During the time of mastication the mouth is shut behind by the curtain of the palate, the anterior surface of which is pressed against the base of the tongue; the food is retained before by the teeth and the lips.

Insalivation of the aliments.—Whenever we have an appetite, the view of food determines a considerable afflux of saliva into the mouth; in some people it is so strong as to be projected to the distance of several feet.

Whilst the aliments are bruised and triturated by the masticating organs, they imbibe, and are penetrated completely by the fluids that are poured into the mouth, and particularly by the saliva. It is easy to conceive that the division of the food and the numerous displacements that it suffers during mastication, singularly favour its mixture with the mucous and salivary juices.

Most of the alimentary substances submitted to the action of the mouth are dissolved or suspended wholly or in part in the saliva, and immediately they become proper for being introduced into the stomach, and are forthwith swallowed.

On account of its viscosity, the saliva absorbs air, by which it is swept in the different motions necessary for mastication; but the quantity of air absorbed in this circumstance is inconsiderable, and has been generally exaggerated.

Of what use is the trituration of food and its mixture with the saliva? Is it a simple division which renders the aliments more proper for the alterations which they undergo in the stomach, or do they suffer the first degree of animalization in the mouth? On this point there is nothing certain known.

Let us remark that mastication and insalivation change the savour and odour of the food; that mastication, sufficiently prolonged, generally renders digestion more quick and easy; that, on the contrary, people who do not chew their food have often on this account very painful and slow digestion.—*Magendie's Physiology.*

MASTICATORY. (*Masticatorium*; from *mastico*, to chew.) A medicine intended for chewing.

MA'STICHE. (From μασσω, to express.) See *Pistacia lentiscus.*

Mastich-herb. See *Thymus mastichina.*

Mastich, Syrian. See *Teucrium marum.*

Mastich-tree. See *Pistacia lentiscus.*

Mastich wood. See *Pistacia lentiscus.*

MASTICHELÆ'UM. (From μαςιχη, mastich, and ελαιον, oil.) Oil of mastich.

MASTI'CHINA. (Diminutive of *mastiche.*) See *Thymus mastichina.*

Masticot. See *Massicot.*

MA'STIX. See *Pistacia lentiscus.*

MASTODY'NIA. (From μαςος, a breast, and οδυνη, pain.) *Nacta.* Phlegmon of the breast of women. This disease may take place at any period of life, but it most commonly affects those who give suck. It is characterised by tumefaction, tension, heat, redness, and pain; and comes sometimes in both breasts, but most commonly in one. Pyrexia generally attends the disease. It is sometimes very quickly formed, and in general without any thing preceding to show it; but now and then a slight shivering is the forerunner. This disease terminates either in resolution, in suppuration, or scirrhus. If the disease is left to itself, it generally terminates in suppuration.

The causes which give rise to this disease, are those which give rise to most of the phlegmasiæ, as cold, violent blows, &c. In women who are lying-in, or giving suck, it mostly arises either from a suppression of the lochia or a retention of milk. Mastodynia is often of long continuance;

it is a very painful disease, but it is seldom fatal, unless when absolutely neglected, when it may run into scirrhus, and finally cancer. The termination of the disease by gangrene is never to be apprehended, at least few, if any, have seen the disease terminate in this way.

MASTOID. (*Mastoideus*; from μαςος, a breast, and ειδος, resemblance.) 1. Those processes of bones are so termed that are shaped like the nipple of the breast, as the mastoid process of the temporal bone, &c.

2. The name of a muscle. See *Sterno-cleido-mastoideus.*

Mastoid foramen. A hole in the temporal bone of the skull.

MASTOIDEUS LATERALIS. A name for the complexus muscle.

MATALI'STA RADIX. A root said to be imported from America, where it is given as a purgative, its action being rather milder than that of jalap.

MA'TER. (Ματηρ, a mother: so called by the Arabians, who thought they gave origin to all other membranes of the body.) 1. Two membranes of the brain had this epithet given them. See *Dura mater*, and *Pia mater.*

2. A name of the herb mugwort, because of its virtue in disorders of the womb.

MATER HERBARUM. Common mugwort. See *Artemisia vulgaris.*

MATER METALLORUM. Quicksilver.

MATER PERLARUM. See *Margarita.*

MATE'RIA. A term given to a substance that is selected for a particular experiment or purpose, which is expressed by adding the name of that purpose; hence *materia medica, materia chemica*, &c.

MATERIA MEDICA. By this term is understood a general class of substances, both natural and artificial, which are used in the cure of diseases.

Cartheuser, Newman, Lewis, Gleditsch, Linnæus, Vogel, Alston, Bergius, Cullen, Murray, Paris, in his excellent work on pharmacology, and other writers on the Materia Medica, have been at much labour to contrive arrangements of these articles. Some have disposed them according to their natural resemblances; others according to their real or supposed virtues; others according to their active constituent principles. These arrangements have their peculiar advantages. The first may be preferred by the natural historian, the second by the physiologist, and the last by the chemist. The pharmacopœias published by the Colleges of Physicians of London, Dublin, and Edinburgh, have the articles of the Materia Medica arranged in alphabetical order; this plan is also adopted by almost all the continental pharmacopœias.

Dr. Cullen has arranged the Materia Medica as follows:—

- NUTRIMENTS, which are
  - Food,
  - Drinks,
  - Condiments;
- MEDICINES which act on the
  - Solids,
    - Simple, as
      - *Astringents,*
      - *Tonics,*
      - *Emollients,*
      - *Corrosives;*
    - Living, as
      - *Stimulants,*
      - *Sedatives,*
        - *Narcotics,*
        - *Refrigerants,*
      - *Antispasmodics.*
  - Fluids
    - Producing a change of fluidity,
      - *Attenuants,*
      - *Inspissants.*
    - Mixture,
      - Correctors of Acrimony,
        - *Demulcents,*
        - *Antacids,*
        - *Antalkalines,*
        - *Antiseptics.*
    - Evacuants; viz.
      - *Errhines,*
      - *Sialagogues,*
      - *Expectorants,*
      - *Emetics,*
      - *Cathartics,*
      - *Diuretics,*
      - *Diaphoretics,*
      - *Emmenagogues.*

The following is the list of articles which come under the preceding classes:—

I. NUTRIMENTS.

α. FRUITS.

a. *Fresh, sweet, acidulous,* as

Prunes

Oranges

Lemons

Raspberries

Red and black currants

Mulberries

Grapes, &c.

b. *Dried, sweet, acidulous,* as

Raisins

Currants

Figs.

β. OLERACEOUS HERBS.

Water-cresses

Dandelion

Parsley

Artichoke.

γ. Roots,

Carrot
Garlick
Satyrion.
6. Seeds and Nuts,
Almonds, sweet and bitter
Walnuts
Olives.
II. MEDICINES.
1. Astringents.
Red rose
Cinquefoil
Tormentil
Madder
Sorrel
Water-dock
Bistort
Fern
Pomegranate
Oak-bark
Galls
Logwood
Quince
Mulberry
Sloe
Gum-arabic
Catechu
Dragon's blood
Alkanet
Balaustine flower
St. John's wort
Millefoil
Plantain
Convallaria
Bear's berry.
2. Tonics.
Gentian
Lesser centaury
Quassia
Simarouba
Marsh trefoil
Fumitory
Camomile
Tansy
Wormwood
Southernwood
Sea-wormwood
Water-germander
Virginian snake-root
Leopard's bane
Peruvian bark.
3. Emollients.
Columniferous,
Marsh mallow
Mallow
Farinaceous,
Quince-seeds
Fænugreek-seed
Linseed.
Various emollients,
Pellitory
Verbascum
White lily.
4. Corrosives.
5. Stimulants.
Verticellated,
Lavender
Balm
Marjoram
Sweet marjoram
Syrian herb mastich
Rosemary
Hyssop
Ivy
Mint
Peppermint
Pennyroyal
Thyme
Mother of thyme
Sage.
Umbellated,
Fennel
Archangel
Anise
Caraway
Coriander
Cumin
Dill
Saxifrage.
Siliquose,
Horse-radish
Water-cress
Mustard
Scurvy-grass.
Alliaceous,
Garlick.
Coniferous,
Fir
Juniper.
Balsamics,
Venice turpentine
Common turpentine
Canada balsam
Copaiba balsam
Tolu balsam
Balm of Gilead.
Resinous,
Guaiacum
Ladanum
Storax
Benzoin.
Aromatics,
Cinnamon
Nutmeg
Mace
Clove
Allspice
Canella
Cascarilla
Black pepper
Long pepper
Indian pepper
Ginger
Lesser cardamom
Zedoary
Virginian snake-root
Ginseng
Aromatic reed.
Acrids,
Wake-robin
Pellitory
Stavesacre.
6. Narcotics.
Rhæadaceous,
White poppy
Red poppy.
Umbellated,
Hemlock
Water hemlock.
Solanaceous,
Belladonna
Henbane
Tobacco
Bitter sweet
Stramonium.
Varia,
Laurel
Camphor
Saffron
Wine.
7. Refrigerants.
Fruits of plants
Acidulous herbs and roots.
8. Antispasmodics.
Fœtid herbs,
Worm-wood
Fœtid goosefoot
Cumin
Pennyroyal
Rue
Savine.
Fœtid gums,
Asafœtida
Galbanum
Opoponax
Valerian.
9. Diluents.
Water.
10. Attenuants.
Alkalis
Sugar
Liquorice
Dried fruits.
11. Inspissants.
Acids
Farinaceous and mucilaginous demulcents.
12. Demulcents.
Mucilaginous,
Gum arabic
—— tragacanth.
Farinaceous,
as
Starch
Bland oils.
13. Antacids.
Alkalies and earths.
14. Antalkalines.
Acids.
15. Antiseptics.
Acid parts of plants
Acescent herbs
Sugar
Siliquose plants
Alliaceous plants
Astringents
Bitters
Aromatics
Essential oils
Camphor
Gum resins
Saffron
Contrayerva
Valerian
Opium
Wine.
16. Errhines.
Asarabacca
White hellebore
Water iris
Pellitory.
17. Sialagogues.
Archangel
Cloves
Masterwort
Tobacco
Pepper
Pellitory.
18. Expectorants.
Ivy
Horehound
Pennyroyal
Elecampane
Florentine orris-root
Tobacco
Squill
Coltsfoot
Benzoin
Storax
Canada balsam
Tolu balsam.
19. Emetics.

Asarabacca
Ipecacuan
Tobacco
Squill
Mustard
Horse-radish
Bitters.

20. CATHARTICUS.
Milder,
Mild acid fruits
Cassia pulp
Tamarind
Sugar
Manna
Sweet roots
Bland oils
Damask rose
Violet
Polypody
Mustard
Bitters
Balsamics.
Acrid,
Rhubarb
Seneka
Broom
Elder
Castor oil
Senna
Black hellebore
Jalap
Scammony
Buckthorn
Tobacco
White hellebore
Coloquintida
Elaterium.

21. DIURETICS.
Parsley
Carrot
Fennel
Pimpinel
Eryngo
Madder
Burdock
Bitter sweet
Wake-robin
Asarabacca
Foxglove
Tobacco
Rue
Savine
Snake-root
Squill
Bitters
Balsamics
Siliquosæ
Alliaceæ.

22. DIAPHORETICS.
Saffron
Bitter-sweet
Opium
Camphor
Contrayerva
Serpentaria
Sage
Water germander
Guaiacum
Sassafras
Seneka
Vegetable acids
Essential oil
Wine
Diluents.

23. EMMENAGOGUES.
Aloes
Fœtid gums
Fœtid plants
Saffron.

The following is the arrangement of the Materia Medica, according to J. Murray, in his Elements of Materia Medica and Pharmacy.

A. General stimulants.
a. Diffusible { Narcotics
Antispasmodics.
b. Permanent { Tonics
Astringents.
B. Local stimulants. Emetics
Cathartics
Emmenagogues
Diuretics
Diaphoretics
Expectorants
Sialagogues
Errhines
Epispastics
C. Chemical remedies. Refrigerants
Antacids
Lithontriptics
Escharotics.
D. Mechanical remedies. Anthelmintics
Demulcents
Diluents
Emollients.

Under the head of NARCOTICS are included—Alkohol. Ether. Camphor. Papaver somniferum. Hyoscyamus niger. Atropa belladonna. Aconitum napellus. Conium maculatum. Digitalis purpurea. Nicotiana tabacum. Lactuca virosa. Datura stramonium. Rhododendron chrysanthemum. Rhus toxicodendron. Arnica montana. Strychnos nux vomica. Prunus lauro-cerasus.

Under the second class, ANTISPASMODICS, are included—Moschus. Castoreum. Oleum animale empyreumaticum. Petroleum. Ammonia. Ferula asafœtida. Sagapenum. Bubon galbanum. Valeriana officinalis. Crocus sativus. Melaleuca leucadendron.

Narcotics used as Antispasmodics—
Ether. Camphor. Opium.

Tonics used as Antispasmodics—
Cuprum. Zincum. Hydrargyrus. Cinchona.

The head of TONICS embraces—

1. From the *mineral* kingdom,

Hydrargyrus. Ferrum. Zincum. Cuprum. Arsenicum. Barytes. Calx. Acidum. Nitricum. Oxy-murias potassæ.

2. From the *vegetable* kingdom;

Cinchona officinalis. Cinchona caribæa. Cinchona floribunda. Cusparia. Aristolochia serpentaria. Dorstenia contrayerva. Croton eleutheria. Calumba. Quassia excelsa. Quassia Simarouba. Swietenia febrifuga. Swietenia mahagoni. Gentiana lutea. Anthemis nobilis. Artemisia absinthium. Chironia centaurium. Marrubium vulgare. Menyanthes trifoliata. Centaurea benedicta. Citrus aurantium. Citrus medica. Laurus cinnamomum. Laurus cassia. Canella alba. Acorus calamus. Amomum zinziber. Kæmferia rotunda. Santalum album. Pterocarpus santalinus. Myristica moschata. Caryophyllus aromaticus. Capsicum annuum. Piper nigrum. Piper longum. Piper cubeba. Myrtus pimenta. Amomum repens. Carum carui. Coriandrum sativum. Pimpinella anisum. Anethum fœniculum. Anethum graveolens. Cuminum cyminum. Angelica archangelica. Mentha piperita. Mentha viridis. Mentha pulegium. Hysopus officinalis.

The class of ASTRINGENTS comprehends the following:—

1. From the *vegetable* kingdom,

Quercus robur. Quercus cerris. Tormentilla erecta. Polygonum bistorta. Anchusa tinctoria. Hæmatoxylon campechianum. Rosa gallica. Arbutus uva ursi. Mimosa catechu. Kino. Pterocarpus draco. Ficus indica. Pistachia lentiscus.

2. From the *mineral* kingdom,

Acidum sulphuricum. Argilla. Super-sulphas argillæ et potassæ. Calx. Carbonas calcis. Plumbum. Zincum. Ferrum. Cuprum.

The articles which come under the head of EMETICS, are

1. From the *vegetable* kingdom.

Calliocca ipecacuanha. Scilla maritima. Anthemis nobilis. Sinapis alba. Asarum Europæum. Nicotiana tabacum.

2. From the *mineral* kingdom.

Antimonium. Sulphas zinci. Sulphas cupri. Subacetas cupri. Ammonia. Hydro-sulphuretum ammoniæ.

CATHARTICS include

Laxatives. Manna. Cassia fistula. Tamarindus. Indica. Ricinus communis. Sulphur. Magnesia.

Purgatives. Cassia senna. Rheum palmatum.

Convolvulus jalapa. Helleborus niger. Bryonia alba. Cucumis colocynthis. Momordica elaterium. Rhamnus catharticus. Aloe perfoliata. Convolvulus scammonia. Gambojia gutta. Submurias hydrargyri. Sulphas magnesiæ. Sulphas sodæ. Sulphas potassæ. Supertartras potassæ. Tartras potassæ et sodæ. Murias sodæ. Terebinthina veneta. Nicotiana tabacum.

The medicines arranged under EMMENAGOGUES, are:

1. From the class of Antispasmodics.

Castoreum. Ferula asafœtida. Bubon galbanum.

2. From the class of Tonics.

Ferrum. Hydrargyrus. Cinchona officinalis.

3. From the class of Cathartics.

Aloe. Helleborus niger. Sinapis alba. Rosmarinus officinalis. Rubia tinctorum. Ruta graveolens. Juniperus sabina.

The class of DIURETICS includes,

1. Saline diuretics.

Supertartras pôtassæ. Nitras potassæ. Murias ammoniæ. Acetas potassæ. Potassa.

2. From the *vegetable* kingdom,

Scilla maritima. Digitalis purpurea. Nicotiana tabacum. Solanum dulcamara. Lactuca virosa. Colchicum autumnale. Gratiola officinalis. Spartium scoparium. Juniperus communis. Copaifera officinalis. Pinus balsamea. Pinus larix.

3. From the *animal* kingdom,

Meloe vesicatorius.

Under the class DIAPHORETICS, are,

Ammonia. Murias ammoniæ. Acetas ammoniæ. Citras ammoniæ. Submurias hydrargyri. Antimonium. Opium. Camphor. Guaiacum officinale. Daphne mezereum. Smilax sarsaparilla. Laurus sassafras. Cochlearia armoracia. Salvia officinalis.

The class EXPECTORANTS comprehends,

Antimonium. Ipecacuanha. Nicotiana tabacum. Digitalis purpurea. Scilla maritima. Allium sativum. Polygala senega. Ammoniacum. Myrrha. Styrax benzoin. Styrax officinalis. Toluifera balsamum. Myrroxylon peruiferum. Amyris gileadensis.

The articles of the class SIALAGOGUES are, Hydrargyrus. Anthemis pyrethrum. Arum maculatum. Amomum zinziber. Daphne mezereum. Nicotiana tabacum.

The class of ERRHINES are, Iris florentina. Æsculus hippocastanum. Origanum majorana. Lavendula spica. Assarum Europæum. Veratrum album. Nicotiana tabacum. Euphorbia officinalis.

In the class EPISPASTICS, and RUBEFACIENTS are, Meloe vesicatorius. Ammonia. Pix Burgundica. Sinapis alba. Allium sativum.

REFRIGERANTS are constituted by the following articles. Citrus aurantium. Citrus medica. Tamarindus Indica. Acidum acetosum. Supertartras potassæ. Nitras potassæ. Boras sodæ.

The list of articles that come under the class ANTACIDS are, Potassa. Soda. Ammonia. Calx. Carbonas calcis. Magnesia.

In the class LITHONTRIPTICS are, Potassa. Carbonas potassæ. Soda. Carbonas sodæ. Sapo albus. Calx.

In the class ESCHAROTICS are, Acida mineralia. Potassa. Nitras argenti. Murias antimonii. Sulphas cupri. Acetas cupri. Murias hydrargyri. Subnitras hydrargyri. Oxydum arsenici album. Juniperus sabina.

In the class ANTHELMINTICS are, Dolichos pruriens. Ferri limatura. Stannum pulveratum. Olea Europæa. Artemisia santonica. Spigelia marilandica. Polypodium filix mas. Tanacetum vulgare. Geoffrœa inermis. Gambojia gutta. Submurias hydrargyri.

DEMULCENTS are, Mimosa nilotica. Astragalus tragacantha. Linum usitatissimum. Althæa officinalis. Malva sylvestris. Glycyrrhiza glabra. Cycas circinalis. Orchis mascula. Maranta arundinacea. Triticum hybernum. Ichthyocolla. Olea Europæa. Amygdalus communis. Sevum ceti. Cera.

Water is the principal article of the class DILUENTS; and as for the last class, EMOLLIENTS, heat conjoined with moisture is the principal, though all unctuous applications may be included.

The New London Pharmacopœia presents us with the following list for the Materia Medica:—

Abietis resina
Absinthium
Acaciæ gummi
Acetosæ folia
Acetosella
Acetum
Acidum aceticum fortius
Acidum citricum
Acidum sulphuricum
Aconiti folia
Adeps
Ærugo
Allii radix
Aloes spicatæ extractum
Althææ folia et radix
Alumen
Ammoniacum
Ammoniæ murias
Amygdala amara et dulcis
Amylum
Anethi semina
Anisi semina
Anthemidis flores
Antimonii sulphuretum
Antimonii vitrum
Argentum
Armoraciæ radix
Arsenicum album
Asari folia
Asafœtidæ gummi resina
Avenæ semina
Aurantii baccæ
Aurantii cortex
Balsamum Peruvianum
Balsamum Tolutanum
Belladonnæ folia
Benzoinum
Bismuthum
Bistorta radix
Cajuputi oleum
Calamina
Calami radix
Calumba
Camphora
Canellæ cortex
Cantharis
Capsici baccæ
Carbo ligni
Cardamines flores
Cardamomi semina
Caricæ fructus
Carui semina
Caryophylli
Caryophyllorum oleum
Cascarillæ cortex
Cassiæ pulpa
Castoreum
Catechu extractum
Centaurii cacumina
Cera alba
Cera flava
Cerevisiæ fermentum
Cetaceum
Cinchonæ lancifoliæ, cordifoliæ et oblongifoliæ cortex
Cinnamomi cortex
Cinnamomi oleum
Coccus
Colchici radix et semina
Colocynthidis pulpa
Conii folia et semina
Contrayerva radix
Copaiba
Coriandri semina
Cornua
Creta
Croci stigmata
Cubeca
Cumini semina
Cupri sulphas
Cuspariæ cortex
Cydoniæ semina
Dauci radix
Dauci semina
Digitalis folia et semina
Dolichi pubes
Dulcamaræ caulis
Elaterii pepones
Elemi
Euphorbiæ gummi resina

Farina
Fœniculi semina
Ferrum
Filicis radix
Fucus
Galbani gummi resina
Gallæ
Gentianæ radix
Glycyrrhizæ radix
Granati cortex
Guaiaci resina et lignum
Hæmatoxyli lignum
Helenium
Hellebori fœtidi folia
Hellebori nigri radix
Hordei semina
Humuli strobili
Hydragyrum
Hyoscyami folia et semina
Ipecacuanhæ radix
Jalapæ radix
Juniperi baccæ et semina
Kino
Krameriæ radix
Lactuca
Lavendulæ flores
Lauri baccæ et folia
Lichen
Limones
Limonum cortex et oleum
Linum catharticum
Lini usitatissimi semina
Magnesiæ subcarbonas
Magnesiæ sulphas
Malva
Manna
Marmor album
Marrubium
Mastiche
Mel
Mentha piperita
Mentha viridis
Menyanthes
Mezerei cortex
Mori baccæ
Moschus
Myristicæ nuclei et oleum expressum
Myrrha
Olibanum
Olivæ oleum
Opium
Opopanacis gummi resina
Origanum
Ovum
Papaveris capsulæ
Petroleum
Pimentæ baccæ
Piperis longi fructus
Piperis nigri baccæ
Pix abietina
Pix liquida
Pix nigra
Plumbi subcarbonas
Plumbi oxydum semivitreum
Porri radix
Potassa impura
Potassæ nitras
Potassæ sulphas
Potassæ supertartras
Pruna
Pterocarpi lignum
Pulegium
Pyrethri radix
Quassiæ lignum
Quercûs cortex
Resina flava
Rhamni baccæ
Rhei radix
Rhœados petala
Ricini semina et oleum
Rosæ caninæ pulpa
Rosæ centifoliæ petala
Rosæ gallicæ petala
Rosmarini cacumina
Rubiæ radix
Rutæ folia
Sabinæ folia
Saccharum
——————— purificatum
Salicis cortex
Sagapenum
Sambuci flores
Sapo durus et mollis
Sarsaparillæ radix
Sassafras lignum et radix
Scammoneæ gummi resina
Scillæ radix
Senegæ radix
Sennæ folia
Serpentariæ radix
Sevum
Simaroubæ cortex
Sinapis semina
Sodæ murias
Sodæ subboras
Sodæ sulphas
Soda impura
Spartii cacumina
Spigeliæ radix
Spiritus rectificatus et tenuior
Spongia
Stramonii folia et semina
Stannum
Staphisagriæ semina
Styracis balsamum
Succinum
Sulphur et sulphur sublimatum
Tabaci folia
Tamarindi pulpa
Taraxaci radix
Tartarum
Terebinthina Canadensis
——————— Chia
——————— vulgaris
Terebinthinæ oleum
Testæ
Tiglii oleum
Tormentillæ radix
Toxicodendri folia
Tragacantha
Tussilago
Valerianæ radix
Veratri radix
Ulmi cortex
Uvæ passæ
Uvæ ursi folia
Zincum   Zingiberis radix.

Materia perlata. If, instead of crystalising the salts contained in the liquor separated from diaphoretic antimony, an acid be poured into it, a white precipitate is formed, which is nothing else but a very refractory calx of antimony.

Materiatu'ra. Castellus explains *morbi materiaturæ* to be diseases of intemperance.

MATLOCK. A village in Derbyshire. It affords a mineral water of the acidulous class: which issues from a limestone rock, near the banks of the Derwent. Several of the springs possess a temperature of 66°. Matlock water scarcely differs from common good spring water, in sensible properties. It is extremely transparent, and exhales no vapour, excepting in cold weather. It holds little or no excess of aërial particles; it curdles soap, when first taken up, but it looses this effect upon long keeping, perhaps from the deposition of its calcareous salts; it appears to differ very little from good spring water when tasted; and its effects seem referrible to its temperature. It is from this latter circumstance that it forms a proper tepid bath for the nervous and irritable, and those of a debilitated constitution; hence it is usually recommended after the use of Bath and Buxton waters, and as preparatory to sea-bathing.

MATRICA'LIA. (*Matricalis*; from *matrix*, the womb. Medicines appropriated to disorders of the uterus.

MATRICA'RIA. (From *matrix*, the womb: so called from its uses in disorders of the womb.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia superflua.*

2. The pharmacopœial name of the Matricaria parthenium. See *Matricaria parthenium.*

Matricaria chamomilla. *Chamæmelum vulgare; Chamomilla nostras; Leucanthemum* of Dioscorides. Common wild corn, or dog's camomile. The plant directed under this name in the pharmacopœias, is the *Matricaria—receptaculis conicis radiis patentibus; squamis calycinis, margine æqualibus*, of Linnæus. Its virtues are similar to those of the *parthenium*, but in a much inferior degree.

Matricaria parthenium. The systematic name of the fever-few. *Parthenium febrifuga.* Common fever-few, or febrifuge, and often, but very improperly, feather-few. Mother's wort. The leaves and flowers of this plant, *Matricaria—foliis compositis, planis; foliolis ovatis, incisis; pedunculis ramosis*, have a strong, not agreeable smell, and a moderately bitter taste, both which they communicate by warm infusion, to water and rectified spirit. The watery infusions, inspissated, leave an extract of considerable bitterness, and which discovers also a saline matter, both to the taste, and in a more sensible manner by throwing up to the surface small crystalline efflorescences in keeping. The peculiar flavour of the matricaria exhales in the evaporation, and impregnates the distilled water, on which also a quantity of essential oil is found floating. The quantity of spirituous extract, according to Cartheuser's experiments, is only about one-sixth the weight of the dry leaves, whereas the watery extract amounts to near one-half. This plant is evidently the *Parthenium* of Dioscorides, since whose time it has been very generally employed for medical purposes. In natural affinity, it ranks with camomile and tansy, and its sensible qualities show it to be nearly allied to them in its medicinal character. Bergius states its virtues to be tonic, stomachic, resolvent, and emmenagogue. It has been given successfully as a vermifuge, and for the cure of intermittents; but its use is most celebrated in female disorders, especially in hysteria; and hence it is supposed to have derived the name matricaria. Its smell, taste, and analysis, prove it to be a medicine of considerable activity; we may, therefore, say, with Murray—*Rarius hodie præscribitur, quam debetur.*

MATRISY'LVA. See *Asperula.*

MA'TRIX. (Ματηρ.) 1. The womb. See *Uterus.*

2. The earthy or stony matter which accompanies ores, or envelopes them in the earth.

MATRONA'LIS. (From *matrona*, a matron: so called because its smell is grateful to women.) The violet.

MATTHIOLUS, PETER ANDREW, was born at Sienna in 1501. He went to study the law at Padua; but disliking that pursuit, he turned his attention to medicine. His father's death interrupted him in his progress; but having conciliated the good opinion of the professors, the degree of doctor was conferred upon him before his departure. He speedily found ample employment in his native place, but afterwards went to Rome, and in 1527 to the court of the prince bishop of Trent. During his residence of fourteen years there, he acquired such general esteem, that on his removal, men, women, and children, accompanied him, calling him their father and benefactor. At Gorizia, where he then settled as public physician, he likewise experienced a signal mark of gratitude; a fire having consumed all his furniture, the people flocked to him next day with presents, which more than compensated his loss, and the magistrates advanced him a year's salary. After twelve years, he accepted an invitation to the Imperial court, where he was highly honoured, and created aulic counsellor: but finding the weight of age pressing upon him, he retired to Trent, where he shortly died of the plague in 1577. He left several works, chiefly relating to the virtues of plants: and that, by which he principally distinguished himself, was a Commentary on the writings of Dioscorides. This was first published in Italian, afterwards translated by him into Latin, with plates, and passed through numerous editions. He certainly contributed much to lay the foundation of botanical science, though he was not sufficiently scrupulous in consulting the original sources, and examining the plants themselves.

MATURA'NTIA. (*Maturans;* from *maturo*, to ripen.) Medicines which promote the suppuration of tumours.

MATURATION. (*Maturatio;* from *maturo*, to make ripe.) A term in surgery, signifying that process which succeeds inflammation, by which pus is collected in an abscess.

MAUDLIN. See *Achillea ageratum.*

MAURICEAU, FRANCIS, was born at Paris, where he studied surgery with great industry for many years, especially at the Hôtel-Dieu. He had acquired so much experience in midwifery, before he commenced public practice, that he rose almost at once to the head of his profession. His reputation was farther increased by his writings, and maintained by his prudent conduct during a series of years; after which he retired into the country, and died in 1709. He published several works, relating to the particular branch of the art which he practised, containing a great store of useful facts, though not well arranged, nor free from the false reasoning prevalent in his time.

MAURO-MARSON. See *Marrubium.*

Maw-worm. See *Ascaris.*

MAXI'LLA. (From μασσαω, to chew.) The jaw, both upper and lower.

MAXILLARE INFERIUS OS. *Maxilla inferior. Mandibula.* The maxilla inferior, or lower jaw, which, in its figure may be compared to a horse-shoe, is at first composed of two distinct bones; but these, soon after birth, unite together at the middle of the chin, so as to form only one bone. The superior edge of this bone has, like the upper jaw, a process, called the *alveolar* process. This, as well as that of the upper jaw, to which it is in other respects a good deal similar, is likewise furnished with cavities for the reception of the teeth. The posterior part of the bone, on each side, rises perpendicularly into two processes, one of which is called the *coronoid*, and the other the *condyloid* process. The first of these is the highest: it is thin and pointed; and the temporal muscle, which is attached to it, serves to elevate the jaw. The condyloid process is narrower, thicker and shorter than the other, terminating in an oblong, rounded head, which is formed for a moveable articulation with the cranium, and is received into the fore-part of the fossa described in the temporal bone. In this joint there is a moveable cartilage, which, being more closely connected to the condyle than to the cavity, may be considered as belonging to the former. This moveable cartilage is connected with both the articulating surface of the temporal bone and the condyle of the jaw, by distinct ligaments arising from its edges all round. These attachments of the cartilage are strengthened, and the whole articulation secured, by an external ligament, which is common to both, and which is fixed to the temporal bone, and to the neck of the condyle. On the inner surface of the ligament, which attaches the cartilage to the temporal bone, and backwards in the cavity, is placed what is commonly called the gland of the joint; at least the ligament is there found to be much more vascular than at any other part. At the bottom of each coronoid process, on its inner part, is a foramen, or canal, which extends under the roots of all the teeth, and terminates at the outer surface of the bone near the chin. Each of these foramina affords a passage to an artery, vein, and nerve, which send off branches to the several teeth.

This bone is capable of a great many motions. The condyles, by sliding from the cavity towards the eminences on each side, bring the jaw horizontally forwards, as in the action of biting; or the condyles only may be brought forwards, while the rest of the jaw is tilted backwards, as is the case when the mouth is open. The condyles may also slide alternately backwards and forwards from the cavity to the eminence, and *vice versâ;* so that while one condyle advances, the other moves backwards, turning the body of the jaw from side to side, as in grinding the teeth. The great use of the cartilages seems to be that of securing the articulation, by adapting themselves to the different inequalities in these several motions of the jaw, and to prevent any injuries from friction. This last circumstance is of great importance where there is so much motion, and, accordingly, this cartilage is found in the different tribes of carnivorous animals, where there is no eminence and cavity, nor other apparatus for grinding.

The alveolar processes are formed of an external and internal plate, united together by thin bony partitions, which divide the processes at the fore-part of the jaw, into as many sockets as there are teeth. But, at the posterior part, where the teeth have more than one root, each root has a distinct cell. These processes in both jaws, begin to be formed with the teeth, accompany them in their growth, and disappear when the teeth fall. So that the loss of the one seems constantly to be attended with the loss of the other.

Maxillare superius os. *Maxilla superior.* The superior maxillary bones constitute the most considerable portion of the upper jaw, are two in number, and generally remain distinct through life. Their figure is exceedingly irregular, and not easily to be described. On each of these bones are observed several eminences. One of these is at the upper and fore-part of the bone, and, from its making part of the nose, is called the *nasal* process. Internally, in the inferior portion of this process, is a fossa, which, with the os unguis, forms a passage for the lachrymal duct. Into this nasal process, likewise, is inserted the short round tendon of the *musculus orbicularis palpebrarum.* Backwards and outwards, from the root of the nasal process, the bone helps to form the lower side of the orbit, and this part is therefore called the *orbitar* process. Behind this orbitar process, the bone forms a considerable tuberosity, and, at the upper part of this tuberosity, is a channel, which is almost a complete hole. In this channel passes a branch of the fifth pair of nerves, which, together with a small artery, is transmitted to the face through the external orbiter foramen, which opens immediately under the orbit. Where the bone on each side is joined to the os malæ, and helps to form the cheeks, is observed what is called the *malar* process. The lower and anterior parts of the bone make a kind of circular sweep, in which are the *alveoli,* or sockets for the teeth; this is called the *alveolar* process. This alveolar process has posteriorly a considerable tuberosity on its internal surface. Above this alveolar process, and just behind the fore-teeth, is an irregular hole, called the *foramen incisivum,* which, separating into two, and sometimes more holes, serves to transmit small arteries and veins, and a minute branch of the fifth pair of nerves to the nostrils. There are two horizontal lamellæ behind the alveolar process, which, uniting together, form part of the roof of the mouth, and divide it from the nose. This partition, being seated somewhat higher than the lower edge of the alveolar process, gives the roof of the mouth a considerable hollowness. Where the ossa maxillaria are united to each other, they project somewhat forwards, leaving between them a furrow, which receives the inferior portion of the septum nasi. Each of these bones is hollow, and forms a considerable sinus under its orbitar part. This sinus, which is usually, though improperly, called *antrum Highmorianum,* is lined with the pituitory membrane. It answers the same purposes as the other sinuses of the nose, and communicates with the nostrils by an opening, which appears to be a large one in the skeleton, but which, in the recent subject, is much smaller. In the fœtus, instead of these sinuses, an oblong depression only is observed at each side of the nostrils, nor is the tuberosity of the alveolar process then formed. On the side of the palate, in young subjects, a kind of fissure may be noticed, which seems to separate the portion of the bone which contains the dentes incisores from that which contains the dentes canini. This fissure is sometimes apparent till the sixth year, but after that period it in general wholly disappears.

The ossa maxillaria not only serve to form the cheeks, but likewise the palate, nose, and orbits; and, besides their union with each other, they are connected with the greatest part of the bones of the face and cranium, viz. with the ossa nasi, ossa malarum, ossa unguis, ossa palati, os frontis, os sphenoides, and os ethmoides.

MAXILLARIS. (From *maxilla;* the jaw.) Maxillary: appertaining to the jaw.

Maxillary artery. *Arteria maxillaris.* A branch of the external carotid. The *external maxillary* is the fourth branch of the carotid; it proceeds anteriorly, and gives off the facial or mental, the coronary of the lips, and the angular artery. The *internal maxillary* is the next branch of the carotid; it gives off the spheno-maxillary, the inferior alveolar, and the spinous artery.

Maxillary gland. *Glandula maxillaris.* The gland so called is conglomerate, and situated under the angles of the lower jaw. The excretory ducts of these glands are called Warthonian, after their discoverer.

Maxillary nerve. *Nervus maxillaris.* The superior and inferior maxillary nerves are branches of the fifth pair, or trigemini. The former is divided into the spheno-palatine, posterior alveolar, and the infra-orbital nerve. The latter is divided into two branches, the internal lingual, and one, more properly, called the inferior maxillary.

May-lily. See *Convallaria majalis.*

May-weed. See *Anthemis cotula.*

MAYERNE, Sir Theodore Turquet de, Baron D'Aubonne, was born at Geneva in 1573, and graduated at Montpelier. He then went to Paris, and, by the influence of Riverius, was appointed in 1600 to attend the Duke de Rohan, in his embassy to the diet at Spire; and also one of the physicians in ordinary to Henry IV. On his return, he settled in Paris as a physician, and gave lectures in anatomy and pharmacy, in which he strongly recommended various chemical remedies: this drew upon him the ill-will of the faculty, and he was anonymously attacked as an enemy to Hippocrates and Galen; whence in his "Apologia," he cleared himself from this imputation, making also some severe strictures on his opponents. They consequently issued a decree against consulting with him; but the esteem of the king supported him against this persecution, and he would have been appointed first physician, had he not refused to embrace the catholic religion. After the assassination of Henry IV. in 1610, he received an invitation from James I. of England, to whom he had been introduced three years before: he accepted the office of his first physician, and passed the remainder of his life in this country. He was admitted to the degree of doctor in both universities, and into the College of Physicians, and met with very general respect. He incurred some obloquy, indeed, on the death of the Prince of Wales, having differed in opinion from the other physicians, but his conduct obtained the written approbation of the king and council. He was knighted in 1624, and honoured with the appointment of physician to the two succeeding monarchs; and accumulated a large fortune by his extensive practice. He died in 1655, and bequeathed his library to the College of Physicians. Several papers, written by him, were published after his death: among which are the cases of many of his distinguished patients, well drawn up.

MAYOW, John, was born in Cornwall in 1645. He studied at Oxford, and took a degree in civil law, but afterwards changed to medicine, which he practised chiefly at Bath; but he died in London at the age of 34. These are the only records of the life of a man, who went before his age in his views of chemical physiology, and anticipated, though obscurely, some of the most remarkable discoveries in pneumatic chemistry, which have since been made. He published at Oxford in 1669 two tracts, one on Respiration, the other on Rickets; which were reprinted five years after with three additional dissertations, one on the Respiration of the Fœtus in Utero et Ovo, another on Muscular Motion and the Animal Spirits, and the remaining one on Saltpetre and the Nitro-aërial Spirit. On this latter his claim above-mentioned chiefly rests, the existence of the nitro-aërial spirit being proved by many ingenious experiments, as a constituent of air, and of nitre, the food of life and flame, agreeing with the oxygen of modern chemists. Much vague speculation, indeed, occurs in the work: but he clearly maintains that this spirit is absorbed by the blood in the lungs, and proves the source of the animal heat, as also of the nervous energy and of muscular motion. He likewise anticipated the mode of operating with aërial fluids in vessels inverted over water, and transferring them from one to another.

Mays, Indian. See *Zea mays.*

MEAD,—1. The name of a physician, Dr. Richard, born near London in 1673. After studying some time at Leyden, and in different parts of Italy, he graduated at Padua in 1695. Then returning to his native country, he settled in practice, and met with considerable success. His first publication, "A Mechanical Account of Poisons," appeared in 1702, and displayed much ingenuity; though he afterwards candidly retracted some of his opinions, as inadequate to explain the functions of a living body. He was soon after elected a member of the Royal Society, and in the following year physician to St. Thomas's Hospital. In 1704, he published a treatise, maintaining the influence of the sun and moon on the human body, arguing from the Newtonian theory of the tides, and the changes effected by those bodies in the atmosphere. In 1707, he received a diploma from Oxford, and about four years after he was appointed to read the anatomical lectures at Surgeons' Hall, which he continued for some time with great applause. In 1714, on the death of his patron, Dr. Radcliffe, he took his house, and being then a fellow of the College of Physicians, and having been called into consultation, in the last illness of Queen Anne, when he displayed superior judgment, he seems to have been regarded among the first of the profession, and soon after, from his extensive engagements, resigned his office at St. Thomas's Hospital. The plague raging at Marseilles in 1719, he was officially consulted on the means of prevention, which led to a publication by him, in the following year, decidedly maintaining its infectious nature, which had been questioned in France, and recommending suitable precautions: this work passed rapidly through many editions. In 1721, he superintended the experiment of inoculating the small-pox in the persons of some criminals; and his report being favourable, the practice was rapidly diffused. He was soon after engaged in a controversy with Dr. Middleton, concerning the condition of physicians among the Romans, which was, however, carried on in a manner honourable to both parties. About the same period Dr. Freind having been committed to the Tower for his political sentiments, Dr. Mead obtained his liberation in a spirited manner, and presented him a considerable sum, received from his patients during his imprisonment. In 1727, he was appointed physician in ordinary to George II. and his professional occupations became so extensive, that he had no leisure for writing. It was not till 20 years after, therefore, that he printed his treatise on Small-pox and Measles, written in a pure Latin style, with a translation in the same language of Rhazes' Commentary on the former disease. In 1749, he published a treatise on the Scurvy, ascribing the disease to moisture and putridity, and recommending Mr. Sutton's ventilator, which was, in consequence of his interposition, received into the navy. His "Medicina Sacra," appeared in the same year, containing remarks on the diseases mentioned in the Scriptures. His last work was a summary of his experience, entitled "Monita et Præcepta Medica," in 1751; it was frequently reprinted, and translated into English. His life terminated in 1754; and a monument was erected to him in Westminster Abbey. He distinguished himself not only in his profession, but he was the greatest patron of science and polite literature of his time; and he made an ample collection of scarce and valuable books, manuscripts, and literary curiosities; to which all respectable persons had free access.

2. An old English liquor made from the honey-combs, from which honey has been drained out by boiling in water, and then fermenting. This is often confounded with metheglin.

Meadow crowfoot. See *Ranunculus acris.*

Meadow, queen of the. See *Spiræa ulmaria.*

Meadow saffron. See *Colchicum.*

Meadow saxifrage. See *Peucedanum silaus.*

Meadow sweet. See *Spiræa ulmaria.*

Meadow thistle, round leaved. See *Cnicus oleraceus.*

MEASLES. See *Rubeola.*

MEASURE. The English measures of capacity, are according to the following table:

One gallon, wine measure, is equal to	four quarts.
One quart, - - -	two pints.
One pint, - - -	28.875 cubic inches.

The pint is subdivided by chemists and apothecaries into 16 ounces.

MEA'TUS. An opening which leads to a canal or duct.

Meatus auditorius externus. The external passage of the ear is lined with the common integuments, under which are a number of glands, which secrete the wax. The use of this duct is to admit the sound to the tympanum, which is at its extremity.

Meatus auditorius internus. The internal auditory passage is a small bony canal, beginning internally by a longitudinal orifice at the posterior surface of the petrous portion of the temporal bone, running towards the vestibulum and cochlea, and there being divided into two less cavities by an eminence. The superior and smaller of these is the orifice of the aqueduct of Fallopius, which receives the portio dura of the auditory nerve: the other inferior and larger cavity is perforated by many small holes, through which the portio mollis of the auditory nerve passes into the labyrinth.

Meatus cæcus. A passage in the throat to the ear, called Eustachian tube.

Meatus cuticulares. The pores of the skin.

Meatus cysticus. The gall-duct.

Meatus urinarius. In women, this is situated in the vagina, immediately below the symphisis of the pubes, and behind the nymphæ. In men, it is at the end of the glans penis.

Mecca balsam. See *Amyris Gileadensis.*

MECHOACAN. See *Convolvulus mechoacanna.*

Mechoaca′nna. (From *Mechoacan*, a province in Mexico, whence it is brought.) See *Convolvulus Mechoacanna.*

Mechoacanna nigra. See *Convolvulus jalapa.*

Me′con. (From μηκος, bulk: so named from the largeness of its head.) The papaver, or poppy.

MECONIC ACID. (*Acidum meconicum;* so called from μηκων, the poppy from which it is procured.) This acid is a constituent of opium. It was discovered by Sertuerner, who procured it in the following way: After precipitating the *morphia*, from a solution of opium, by ammonia, he added to the residual fluid a solution of the muriate of barytes. A precipitate is in this way formed, which is supposed to be a quadruple compound, of barytes, morphia, extract and the meconic acid. The extract is removed by alcohol, and the barytes by sulphuric acid; when the meconic acid is left, merely in combination with a portion of the morphia; and from this it is purified by successive solutions and evaporations. The acid, when sublimed, forms long colourless needles; it has a strong affinity for the oxide of iron, so as to take it from the muriatic solution, and form with it a cherry-red precipitate. It forms a crystallisable salt with lime, which is not decomposed by sulphuric acid; and what is curious, it seems to possess no particular power over the human body, when received into the stomach. The essential salt of opium, obtained in Derosne's original experiments, was probably the meconiate of morphia.

Robiquet has made a useful modification of the process for extracting meconic acid. He treats the opium with magnesia, to separate the morphia, while meconiate of magnesia is also formed. The magnesia is removed by adding muriate of barytes, and the barytes is afterwards separated by dilute sulphuric acid. A larger proportion of meconic acid is thus obtained.

Me′conis. (From μηκων, the poppy: so called because its juice is soporiferous, like the poppy.) The lettuce.

MECO′NIUM. (From μηκων, the poppy.) 1. The inspissated juice of the poppy. Opium.

2. The green excrementitious substance that is found in the large intestines of the fœtus.

MEDIAN. *Medianus.* This term is applied to vessels, &c. from their situation between others.

Median nerve. The second branch of the brachial plexus.

Median vein. The situation of the veins of the arms is extremely different in different individuals. When a branch proceeds near the bend of the arm, inwardly from the basilic vein, it is termed the *basilic median;* and when a vein is given off from the cephalic in the like manner, it is termed the *cephalic median.* When these two veins are present, they mostly unite just below the bend of the arm, and the common trunk proceeds to the cephalic vein.

Media′num. The *Mediastinum.*

MEDIASTI′NUM. (*Quasi in medio stans,* as being in the middle.) The membraneous septum, formed by the duplicature of the pleura, that divides the cavity of the chest into two parts. It is divided into an anterior and posterior portion.

Mediastinum cerebri. The falciform process of the dura mater.

ME′DICA. (*Medicus;* from *medico,* to heal.) 1. Belonging to medicine.

2. (From Media, its native soil.) A sort of trefoil.

MEDICA′GO. (So called by Tourneforte; from *medica,* which is indeed the proper name of the plant—μηδικη, of Dioscorides.) The name of a genus of plants in the Linnæan system. Class, *Diadelphia;* Order, *Decandria.* The herb trefoil.

MEDICAMENTA′RIA. Pharmacy, or the art of making and preparing medicines.

MEDICAME′NTUM. (From *medico,* to heal.) A medicine.

MEDICA′STER. A pretender to the knowledge of medicine; the same as quack.

MEDICI′NA. (From *medico,* to heal.) Medicine. 1. The medical art: applied to the profession generally.

2. Any substance that is exhibited with a view to cure or allay the violence of a disease. It is also very frequently made use of to express the healing art, when it comprehends anatomy, physiology, and pathology.

Medicina diætetica. That department of medicine which regards the regulation of regimen, or the non-naturals.

Medicina diasostica. That part of medicine which preserves health.

Medicina gymnastica. That part of medicine which relates to exercise.

Medicina hermetica. The application of chemical remedies.

Medicina prophylactica. That part of medicine which relates to preservation of health.

Medicina tristitiæ. Common saffron.

MEDICINAL. (*Medicinalis;* from *medicina.*) Medicinal, having a power to restore health, or remove disease.

Medicinal days. Such days were so called by some writers, wherein the crisis or change is expected, so as to forbid the use of medicines, in order to wait nature's effort, and require all the assistance of art to help forward, or prepare the humours for such a crisis; but it is most properly used for those days wherein purging or any other evacuation, is most conveniently complied with.

Medicinal hours—are those wherein it is supposed that medicines may be taken to the greatest advantage, commonly reckoned in the morning fasting, about an hour before dinner, about four hours after dinner, and at going to bed; but in acute cases, the times are to be governed by the symptoms and aggravation of the distemper.

Medina. A species of ulcer, mentioned by Paracelsus.

MEDINE′NSIS VENA. (*Medinensis;* so called because it is frequent at Medina, and improperly called *vena* for *vermis;* and sometimes *nervus medinensis,* and no one knows why.) *Dracunculus; Gordius medinensis,* of Linnæus. The muscular hair-worm. A very singular animal, which, in some countries, inhabits the cellular membrane between the skin and muscles. See *Dracunculus.*

MEDITU'LLIUM. (From *medius*, the middle.) See *Diploë.*

ME'DIUS VENTER. The middle venter, the thorax, or chest.

MEDLAR. See *Mespilus.*

MEDU'LLA. (*Quasi in medio ossis.*)

1. The marrow. See *Marrow.*

2. The pith or pulp of vegetables. The centre or heart of a vegetable within the wood. "This," says Dr. E. Smith, "in parts most endowed with life, as roots and young growing stems or branches, is a tolerably firm juicy substance, of a uniform texture, and commonly a pale green or yellowish colour. In many annual stems the petal, abundant and very juicy while they are growing, becomes little more than a web, lining the hollow of the complete stem; as in some thistles. Concerning the nature and functions of this part various opinions have been held. Du Hamel considered it as merely cellular substance, connected with what is diffused through the whole plant, combining its various parts, but not performing any remarkable office in the vegetable economy. Linnæus, on the contrary, thought it the seat of life, and source of vegetation; that its vigour was the main cause of the propulsion of the branches, and that the seeds were more especially formed from it. This latter hypothesis is not better founded than his idea of the pith adding new layers to the wood. In fact, the pith is soon obliterated in the trunk of many trees; which, nevertheless, keep increasing for a long series of years, by layers of wood, added every year from the bark, even after the heart of the tree is become hollow from decay.

Some considerations have led Sir James Smith to hold a medium opinion between these two extremes. There is in certain respects, he observes, an analogy between the medulla of plants and the nervous system of animals. It is no less assiduously protected than the spinal marrow or principal nerve. It is branched off and diffused through the plant, as nerves are through the animal; hence it is not absurd to presume that it may, in like manner, give life and vigour to the whole, though by no means any more than nerves, the organ or source of nourishment.

It is certainly most vigorous and abundant in young and growing branches and must be supposed to be subservient, in some way or other, to their increase.

Mr. Lindsay, of Jamaica, thought he demonstrated the medulla in the leafstalk of the *Mimosa pudica*, or sensitive plant.

Knight supposes the medulla may be a reservoir of moisture, to supply the leaves whenever an excess of perspiration renders such assistance necessary, but it should be recollected that all the moisture in the medulla of a whole plant is, in some cases, too little to supply one hour's perspiration of a single leaf, and it is not found that the moisture of the medulla varies, let the leaves be ever so flaccid.

3. The white substance of the brain is called medulla, or the medullary part, to distinguish it from the cortical.

MEDULLA CASSIÆ. The pulp of the cassiæ fistularis. See *Cassia fistularis.*

MEDULLA OBLONGATA. *Cerebrum elongatum.* The medullary substance that lies within the cranium, upon the basillary process of the occipital bone. It is formed by the connexion of the crura cerebri and crura cerebelli, and terminates in the spinal marrow. It has several eminences, viz. pons varolii, corpora pyramidalia, and corpora olivaria.

MEDULLA SPINALIS. *Cerebrum elongatum. Æon.* The spinal marrow. A continuation of the medulla oblongata, which descends into the specus vertebralis from the foramen magnum occipitale, to the third vertebra of the loins, where it terminates in a number of nerves, which, from their resemblance, are called *cauda equina.* The spinal marrow is composed, like the brain, of a corticle and medullary substance; the former is placed internally. It is covered by a continuation of the dura mater, pia mater, and tunica arachnoidea. The use of the spinal marrow is to give off, through the lateral or intervertebral foramina, thirty pairs of nerves, called cervicle, dorsal, lumbar, and sacral nerves.

MEDULLARY. (*Medullaris;* from *medulla*, marrow.) Like unto marrow.

MEDULLARY SUBSTANCE. The white or internal substance of the brain is so called. See *Cerebrum.*

MEDULLIN. The name given by Dr. John to the porous pith of the sun-flower.

MEERSCHAM. *Kessecil* of Kirwan. A mineral composed of silica, magnesia, lime-water, and carbonic acid, of a yellowish and greyish white colour, and greasy feel, and soft when first dry. It lathers like soap, and is used by the Tartars for washing. In Turkey they make tobacco pipes from meerschaum, dug in Natolia and near Thebes.

MEGALOSPLA'NCHNUS. (From μεγας, great, and σπλαγχνον, a bowel.) Having some of the viscera enlarged.

ME'GRIM. A species of head-ache; a pain generally affecting one side of the head, towards the eye, or temple, and arising from the state of the stomach.

MEIBOMIUS, HENRY, was born at Lubeck in 1638. After studying in different universities, he graduated at Angers, and afterwards was appointed professor of medicine at Helmstadt, where he continued till his death in 1700. He published several works and commentaries on those of others. That which chiefly illustrates his name is entitled "De Vasis Palpebrarum novis," printed in 1666. He seems to have contemplated a history of medicine, and published a letter on the subject, which indeed his father had begun; but the difficulties, which he met with in investigating the medicine of the Arabians, arrested his progress.

MEIBOMIUS'S GLANDS. *Meibomii glandulæ.* The small glands which are situated between the conjunctive membrane of the eye and the cartilage of the eye-lid, first described by Meibomius.

MEIONITE. Prismatico-pyramidal felspar. This mineral occurs along with ceylanite, and nepheline, in granular limestone, at Monte Somma, near Naples.

MEL. *Honey.* A substance collected by bees from the nectary of flowers, resembling sugar in its elementary properties. It has a white or yellowish colour, a soft and grained consistence, and a saccharine and aromatic smell. It is supposed to consist of sugar, mucilage, and an acid. Honey is an excellent food, and a softening and slightly aperient remedy; mixed with vinegar, it forms *oxymel*, and is used in various forms, in medicine and pharmacy. It is particularly recommended to the asthmatic, and those subject to gravel complaints, from its detergent nature. Founded upon the popular opinion of honey, as a pectoral remedy, Dr. Hill's balsam of honey, a quack medicine, was once in demand; but this, besides honey, contained balsam of Tolu, or gum benjamin, in solution.

Mel acetatum. See *Oxymel.*

Mel boracis. Honey of borax.—Take of borax, powdered, a drachm; clarified honey, an ounce. Mix. This preparation is found very useful in aphthous affections of the fauces.

Mel despumatum. Clarified honey. Melt honey in a water bath, then remove the scum.

Mel rosæ. Rose honey.—Take of red-rose petals, dried, four ounces; boiling water, three pints; clarified honey, five pounds. Macerate the rose petals in the water, for six hours, and strain; then add the honey to the strained liquor, and, by means of a water bath, boil it down to a proper consistence. An admirable preparation for the base of various gargles and collutories. It may also be employed with advantage, mixed with extract of bark, or other medicines, for children who have a natural disgust to medicines.

Mel scillæ. See *Oxymel scillæ.*

Me'la. (From μαω, to search.) A probe.

MELÆ'NA. (From μελας, black.) The black vomit. The black disease. Μελαινα νουσος, of the Greeks. Hippocrates applies this name to two diseases. In the first, the patient vomits black bile, which is sometimes bloody and sour; sometimes he throws up a thin saliva; and at others a green bile, &c. In the second, the patient is as described in the article *Morbus niger.* See *Morbus niger.*

Melaina nosos. See *Melæna.*

MELALEU'CA. (From μελας, black, and λευκος, white: so named by Linnæus, because the principal, and indeed original, species was called *leucadendron*, and *arbor alba;* words synonymous with its appellation in the Malay tongue, *Caja-puti*, or white-tree, but it is not known why the idea of black was associated with white.) The name of a genus of plants in the Linnæan system. Class, *Polyandria;* Order, *Icosandria.*

Melaleuca leucadendron. The systematic name of the plant which is said to afford the cajeput oil. *Oleum cajeputæ; Oleum Wittnebianum; Oleum volatile melaleucæ; Oleum cajeput.* Thunberg says cajeput oil has the appearance of inflammable spirit, is of a green colour, and so completely volatile, that it evaporates entirely, leaving no residuum; its odour is of the camphoraceous kind, with a terebinthinate admixture. Goetz says it is limpid, or rather yellowish. It is a very powerful medicine, and in high esteem in India and Germany, in the character of a general remedy in chronic and painful diseases: it is used for the same purposes for which we employ the officinal æthers, to which it seems to have a considerable affinity; the cajeput, however, is more potent and pungent; taken into the stomach, in the dose of five or six drops, it heats and stimulates the whole system, proving, at the same time, a very certain diaphoretic, by which probably the good effects it is said to have in dropsies and intermittent fevers, are to be explained. For its efficacy in various convulsive and spasmodic complaints, it is highly esteemed. It has also been used both internally and externally, with much advantage, in several other obstinate disorders: as palsies, hypochondriacal, and hysterical affections, deafness, defective vision, tooth-ache, gout, rheumatism, &c. The dose is from two to six, or even twelve drops. The tree which affords this oil, by distillation of its leaves, generally was supposed to be the *Melaleuca leucadendron* of Linnæus, but it appears from the specimens of the tree producing the true oil, sent home from India, by Christopher Smith, that it is another species, which is therefore named *Melaleuca cajaputi.*

MELAMEMA. (From μελας, black, and αιμα, blood.) A term applied to blood when it is of a morbidly dark colour.

MELAMPHY'LLUM. (From μελας, black, and φυλλον, a leaf: so named from the blackness of its leaf.) See *Acanthus mollis.*

MELAMPO'DIUM. (From *Melampus*, the shepherd who first used it.) Black hellebore. See *Helleborus niger.*

Melanago'ga. (From μελας, black, and αγω, to expel.) Medicines which purge off black bile.

Melanchlo'rus. Μελαγχλωρος. 1. A livid colour of the skin.

2. The black jaundice.

MELANCHO'LIA. (From μελας, black, and χολη, bile; because the ancients supposed that it proceeded from a redundance of black bile.) Melancholy madness. A disease in the class *Neuroses*, and order *Vesaniæ*, of Cullen, characterised by erroneous judgment, but not merely respecting health, from imaginary perceptions, or recollection influencing the conduct and depressing the mind with ill-grounded fears; not combined with either pyrexia or comatose affections; often appearing without dyspepsia, yet attended with costiveness, chiefly in persons of rigid fibres and torpid insensibility. See *Mania.*

MELANITE. A velvet-black coloured mineral in roundish or crystallised grains, found in a rock at Frascate near Rome.

MELANO'MA. (From μελας, black.) *Melanosis.* A rare disease which is found under the common integuments, and in the viscera, in the form of a tubercle, of a dark soot-black colour.

MELANO'PIPER. (From μελας, black, and πεπερι, pepper.) See *Piper nigrum.*

Melanorrhi'zon. (From μελας, black, and ριζα, a root.) A species of hellebore with black roots. See *Helleborus niger.*

MELANO'SIS. See *Melanoma.*

Melante'ria. (From μελας, black: so called because it is used for blacking leather.) Green vitriol, or sulphate of iron.

Melanthelæ'um. (From μελας, black, and ελαιον, oil.) Oil expressed from the black seeds of the Nigella sativa.

Mela'nthium. (From μελας, black: so named from its black seed.) The Nigella sativa, or herb fennel flower.

ME'LAS. (From μελας, black.) *Vitiligo nigra; Morphæa nigra; Lepra maculosa nigra.* A disease that appears upon the skin in black or brown spots, which very frequently penetrate deep, even to the bone, and do not give any pain, or uneasiness. It is a disease very frequent in, and endemial to, Arabia, where it is supposed to be produced by a peculiar miasma.

MELA'SMA. (From μελας, black.) *Melasmus.* A disease that appears not unfrequently upon the tibia of aged persons, in form of a livid black spot, which, in a day or two, degenerates into a very foul ulcer.

MELASPE'RMUM. (From μελας, black, and σπερμα, seed.) See *Nigella sativa.*

MELASSES. Treacle. The black empyreumatic syrup which exists in raw sugar.

MELASSIC ACID. The acid present in melasses, which has been thought a peculiar acid by some, by others the acetic.

Me'lca. (From αμελγω, to milk.) Milk. A food made of acidulated milk.

Me'le. (From μαω, to search.) A probe.

MELEA'GRIS. (From *Meleager*, whose

sisters were fabled to have been turned into this bird.) 1. The guinea-fowl.

2. A species of *fritillaria:* so called because its flowers are spotted like a guinea-fowl.

MELEGE′TA. Grains of paradise.

MELEGUETTA. Grains of paradise. See *Amomum granum paradisi.*

MELEI′OS. (From *Melos*, the island where it is made.) A species of alum.

MELI. Μελι. Honey. See *Mel.*

MELICE′RIA. See *Meliceris.*

MELI′CERIS. (From μελι, honey, and κερος, wax.) *Meliceria.* An encysted tumour, the contents of which resemble honey in consistence and appearance.

MELI′CRATON. (From μελι, honey, and κεραννυμι, to mix.) Wine impregnated with honey.

MELIGEI′ON. (From μελι, honey.) A fœtid humour, discharged from ulcers attended with a caries of the bone, of the consistence of honey.

MELILOT. See *Melilotus.*

MELILO′TUS. (From μελι, honey, and λωτος, the lotus: so called from its smell, being like that of honey.) See *Trifolium melilotus officinalis.*

MELIME′LUM. (From μελι, honey, and μηλον, an apple: so named from its sweetness.) Paradise apple, the produce of a dwarf wild apple-tree.

MELI′NUM. (From μελον, an apple.) Oil made from the flowers, or the fruit of the apple-tree.

MELIPHY′LLUM. (From μελι, honey, and φυλλον, a leaf: so called from the sweet smell of of its leaf, or because bees gather honey from it.) See *Melissa.*

MELI′SSA. (From μελισσα, a bee; because bees gather honey from it.) The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Gymnospermia.* Balm.

MELISSA CALAMINTHA. The systematic name of the common calamint. *Calamintha; Calamintha vulgaris; Calamintha officinarum; Melissa—pedunculis axillaribus, dichotomis, longitudine foliorum*, of Linnæus. This plant smells strongly like wild mint, though more agreeable; and is often used by the common people, in form of tea, against weakness of the stomach, flatulent colic, uterine obstructions, hysteria, &c.

MELISSA CITRINA. See *Melissa officinalis.*

MELISSA GRANDIFLORA. The systematic name of the mountain calamint. *Calamintha magno flore; Calamintha montana.* This plant has a moderately pungent taste, and a more agreeable aromatic smell than the common calamint, and appears to be more eligible as a stomachic.

MELISSA NEPETA. Field calamint. Spotted calamint. *Calamintha anglica; Calamintha pulegii odore; Nepeta agrestis.* It was formerly used as an aromatic.

MELISSA OFFICINALIS. The systematic name of balm. *Citrago; Citraria; Melissophyllum; Mellitis; Cedronella; Apiastrum; Melissa citrina; Erotion.* A native of the southern parts of Europe, but very common in our gardens. In its recent state, it has a roughish aromatic taste, and a pleasant smell of the lemon kind. It was formerly much esteemed in nervous diseases, and very generally recommended in melancholic and hypochondriacal affections; but, in modern practice, it is only employed when prepared as tea, as a grateful diluent drink in fevers, &c.

MELISSA TURCICA. See *Dracocephalum moldavica.*

MELISSOPHY′LLUM. (From μελισσα, baum, and φυλλον, a leaf. A species of melittis, with leaves resembling baum. See *Melittis melissophyllum.*

MELITI′SMUS. (From μελι, honey.) A linctus, prepared with honey.

MELI′TTIS. (From μελιτ7α, which in the Attic dialect is the name of a bee; so that this word is, in fact, equivalent to *Melissa*, and was adopted by Linnæus, therefore, for the bastard balm.) The name of a genus of plants. Class, *Didynamia;* Order, *Gymnospermia.* Bastard balm.

MELITTIS MELISSOPHYLLUM. The systematic name of the mountain balm, or nettle. *Sophyllum.* This elegant plant is seldom used in the present day; it is said to be of service in uterine obstructions and calculous diseases.

MELITTO′MA. (From μελι, honey.) A confection made with honey. Honey-dew.

MELIZO′MUM. (From μελι, honey, and ζωμος, broth.) Honey broth. A drink prepared with honey, like mead.

MELLA′GO. (From *mel*, honey.) Any medicine which has the consistence and sweetness of honey.

MELLATE. A compound of mellitic acid with salifiable bases.

MELLICERIS. See *Meliceris.*

MELLILO′TUS. See *Melilotus.*

MELLI′NA. (From *mel*, honey.) Mead. A sweet drink prepared with honey.

MELLI′TA. (From *mel*, honey.) Preparations of honey.

MELLITE. Mellilite. Honey-stone. A mineral of a honey yellow colour, slightly resino-electric by friction, hitherto found only at Artern in Thuringia.

MELLITIC ACID. (*Acidum melliticum; from mellilite*, the honey-stone, from which it is obtained.) "Klaproth discovered in the mellilite, or honey-stone, what he conceives to be a peculiar acid of the vegetable kind, combined with alumina. This acid is easily obtained by reducing the stone to powder, and boiling it in about seventy times its weight of water; when the acid will dissolve, and may be separated from the alumina by filtration. By evaporating the solution, it may be obtained in the form of crystals. The following are its characters:—

It crystallises in fine needles or globules by the union of these, or small prisms. Its taste is at first a sweetish-sour, which leaves a bitterness behind. On a plate of hot metal it is readily decomposed, and dissipated in copious grey fumes, which affect not the smell, leaving behind a small quantity of ashes, that do not change either red or blue tincture of litmus. Neutralised by potassa it crystallises in groups of long prisms: by soda, in cubes, or triangular laminæ, sometimes in groups, sometimes single; and by ammonia, in beautiful prisms with six planes, which soon lose their transparency, and acquire a silver-white hue. If the mellitic acid be dissolved in lime water, and a solution of calcined strontian or barytes be dropped into it, a white precipitate is thrown down, which is redissolved on adding muriatic acid. With a solution of acetate of barytes, it produces likewise a white precipitate, which nitric acid redissolves. With solution of muriate of barytes, it produces no precipitate, or even cloud; but after standing some time, fine transparent needly crystals are deposited. The mellitic acid produces no change in a solution of nitrate of silver. From a solution of nitrate of mercury, either hot or cold, it throws down a copious white precipitate, which an addition of nitric acid immediately redissolves. With nitrate of iron it gives an abundant precipitate of a dun yellow colour, which may be redissolved by muriatic acid. With a solution of acetate of lead, it produces an abundant precipitate, immediately redissolved on adding nitric acid. With acetate of copper, it gives a greyish-green precipitate; but it does not affect a solution of muriate of copper. Lime water precipitated by it, is immediately redissolved on adding nitric acid."—*Ure's Chem. Dict.*

ME′LO. See *Cucumis melo.*

Meloca′rpus. (From μηλον, an apple, and καρπος, fruit; from its resemblance to an apple.) The fruit of the aristolochia, or its roots.

ME′LOE. An insect called the blossom eater. A genus of the order *Coleoptera.* Some of its species were formerly used medicinally.

Meloe vesicatorius. See *Cantharis.*

MELON. See *Cucumis melo.*

Melon, musk. See *Cucumis melo.*

Melon, water. See *Cucurbita citrullus.*

Me′lon. Μηλον. A disorder of the eye, in which the ball of the eye is pressed forward from the socket.

MELO′NGENA. *Mala insana. Solanum pomiferum.* Mad apple. The Spaniards and Italians eat it in sauce and in sweet meats. The taste somewhat resembles citron. See *Solanum melongena.*

Melo′sis. Μηλωσις. A term which frequently occurs in Hippocrates, De Capitis Vulneribus, for that search into wounds which is made by surgeons with the probe.

Melo′tis. Μηλωτις. A little probe and that particular instrument contrived to search or cleanse the ear with, commonly called *Auriscalpium.*

MELO′THRIA. (A name borrowed by Linnæus in his *Hortus Cliffortianus*; from the μηλωϑρον, of Dioscorides.) The name of a genus of plants. Class, *Triandria*; Order, *Monogynia.*

Melothria pendula. The systematic name of the small creeping cucumber plant. The American bryony. The inhabitants of the West Indies pickle the berries of this plant, and use them as we do capers.

Melyssophy′llum, (From μελισσα, balm, and φυλλον, a leaf.) See *Melittis.*

MEMBRA′NA. See *Membrane.*

Membrana hyaloidea. *Membrana arachnoidea.* The transparent membrane which includes the vitreous humour of the eye.

Membrana pupillaris. *Velum pupillæ.* A very delicate membrane of a thin and vascular texture, and an ash colour, arising from the internal margin of the iris, and totally covering the pupil in the fœtus before the sixth month.

Membrana ruyschiana. The celebrated anatomist Ruysch discovered that the choroid membrane of the eye was composed of two laminæ. He gave the name of membrana ruyschiana to the internal lamina, leaving the old name of choroides to the external.

Membrana schneideriana. The very vascular pituitary membrane which lines the nose and its cavities; secretes the mucus of that cavity, and is the bed of the olfactory nerves.

Membrana tympani. The membrane covering the cavity of the drum of the ear, and separating it from the meatus auditorius externus. It is of an oval form, convex below the middle, towards the hollow of the tympanum, and concave towards the meatus auditorius, and convex above the meatus, and concave towards the hollow of the tympanum. According to the observations of anatomists, it consists of six laminæ; the first and most external, is a production of the epidermis; the second is a production of the skin lining the auditory passage; the third is cellular membrane, in which the vessels form an elegant network; the fourth is shining, thin, and transparent, arising from the periosteum of the meatus; the fifth is cellular membrane, with a plexus of vessels like the third; and the sixth lamina, which is the innermost, comes from the periosteum of the cavity of the tympanum. This membrane, thus composed of several laminæ, has lately been discovered to possess muscular fibres.

MEMBRANACEUS. Membranaceous: Applied to leaves, pods, &c. of a thin and pliable texture, as the leaf of the Magnolia purpurea, and several capsules, ligaments, &c.

MEMBRANOLO′GIA. (From *membrana*, a membrane, and λογος, a discourse.) Membranology. That which relates to the common integuments and membranes.

MEMBRANE. *Membrana.* 1. In anatomy. A thin expanded substance, composed of cellular texture, the elastic fibres of which are so arranged and woven together, as to allow of great pliability. The membranes of the body are various, as the skin, peritoneum, pleura, dura mater, &c. &c.

2. In botany. See *Testa.*

MEMBRANO′SUS. See *Tensor vaginæ femoris.*

Membra′nus. See *Tensor vaginæ femoris.*

Memo′riæ os. See *Occipital bone.*

MEMORY. *Memoria.* The brain is not only capable of perceiving sensations, but it possesses the faculty of reproducing those it has already perceived. This cerebral action is called remembrance, when the ideas are reproduced which have not been long received: it is called recollection, when the ideas are of an older date. An old man who recalls the events of his youth has recollection; he who recalls the sensations which he had last year, has memory, or remembrance.

Reminiscence is an idea produced which one does not remember having had before.

In childhood and youth memory is very vivid as well as sensibility: it is therefore at this age that the greatest variety of knowledge is acquired, particularly that sort which does not require much reflection; such as history, languages, the descriptive science, &c. Memory afterwards weakens along with age: in adult age it diminishes; in old age it fails almost completely. There are, however, individuals who preserve their memory to a very advanced age; but if this does not depend on great exercise, as happens with actors, it exists often only to the detriment of the other intellectual faculties.

The sensations are recalled with ease in proportion as they are vivid. The remembrance of internal sensations is almost always confused; certain diseases of the brain destroy the memory entirely.

MENACHANITE. A mineral of a greyish black colour, found accompanied with fine quartz sand in the bed of a rivulet, which enters the valley of Manaccan, in Cornwall.

MENAGOGUE. See *Emmenagogue.*

MENDO′SUS. (From *mendax*, counterfeit.) This term is used, by some, in the same sense as spurious, or illegitimate; *Mendosæ costæ*, false or spurious ribs; *Mendosa sutura*, the squamous suture or bastard suture of the skull.

MENILITE. A sub-species of indivisible quartz. It is of two kinds, the brown and the grey.

Meningo′phylax. (From μηνιγξ, a membrane, and ψυλασσω, to guard.) An instrument to guard the membranes of the brain, while the bone is cut, or rasped, after the operation of the trepan.

ME'NINX. (From μενω, to remain.) Before the time of Galen, meninx was the common term of all the membranes of the body, afterwards it was appropriated to those of the brain. See *Dura mater*, and *Pia mater*.

MENISPERMIC ACID. (*Acidum menispermicum*; from *menispermum*, the name of the plant in the berries of which it exists.) The seeds of *Menispermum cocculus* being macerated for 24 hours in 5 times their weight of water, first cold, and then boiling hot, yield an infusion, from which solution of sub-acetate of lead throws down a menispermate of lead. This is to be washed and drained, diffused through water, and decomposed by a current of sulphuretted hydrogen gas. The liquid thus freed from lead, is to be deprived of sulphuretted hydrogen by heat, and then forms solution of menispermic acid. By repeated evaporations and solutions in alkohol, it loses its bitter taste, and becomes a purer acid. It occasions no precipitate with lime water; with nitrate of barytes it yields a grey precipitate; with nitrate of silver, a deep yellow; and with sulphate of magnesia, a copious precipitate.

MENISPE'RMUM. (From μηνη, the moon, and σπερμα, seed, in allusion to the crescent-like form of the seed.) Moon-seed. The name of a genus of plants. Class, *Diœcia*; Order, *Dodecandria*.

MENISPERMUM COCCULUS. The systematic name of the plant, the berries of which are well known by the name of *Cocculus indicus*. Indian berries, or Indian cockles; *Coccus indicus*; *Cocculæ officinarium*; *Cocci orientales*. The berry, the produce of the *Menispermum—foliis cordatis, retusis, mucronatis*; *caule lacero*, of Linnæus, is rugous and kidney-shaped, and contains a white nucleus. It is brought from Malabar and the East Indies. It is poisonous if swallowed, bringing on nausea, fainting, and convulsions. The berries possess an enebriating quality, and are supposed to impart that power to most of the London porter. Whilst green, they are used by the Indians to catch fish, which they have the power of intoxicating, and killing. In the same manner they catch birds, making the berry into a paste, forming it into small seeds, and putting these in places where they frequent. A peculiar acid called *menispermic*, is obtained from these berries.

By recent chemical analysis this seed is found to contain, 1*st*, about one-half of its weight of a concrete fixed oil; 2*d*, an albuminous vegeto-animal substance; 3*d*, a peculiar colouring matter; 4*th*, one-fiftieth of *picrotoxia*; 5*th*, one-half its weight of fibrous matter; 6*th*, bimalate of lime and potassa; 7*th*, sulphate of potassa; 8*th*, muriate of potassa; 9*th*, phosphate of lime; 10*th*, a little iron and silica. It is poisonous; and is frequently employed to intoxicate or poison fishes. The deleterious ingredient is the Picrotoxia.

The poisonous principle called *picrotoxia* is obtained in the following way: "To the filtered decoction of these berries add acetate of lead, while any precipitate falls. Filter and evaporate the liquid cautiously to the consistence of an extract. Dissolve in alkohol of 0.817, and evaporate the solution to dryness. By repeating the solutions and evaporations, we at last obtain a substance equally soluble in water and alkohol. The colouring matter may be removed by agitating it with a little water. Crystals of pure picrotoxia now fall, which may be washed with a little alkohol.

The crystals are four-sided prisms, of a white colour, and intensely bitter taste. They are soluble in 25 times their weight of water, and are not precipitable by any known re-agent. Alkohol, sp. gr. 0.810, dissolves one-third of its weight of picrotoxia. Pure sulphuric æther dissolves 2-5ths of its weight.

Strong sulphuric acid dissolves it, but not when much diluted. Nitric acid converts it into oxalic acid. It dissolves and neutralizes in acetic acid, and falls when this is saturated with an alkali. It may therefore be regarded as a vegeto-alkali itself. Aqueous potassa dissolves it, without evolving any smell of ammonia. It acts as an intoxicating poison.

Sulphate of picrotoxia must be formed by dissolving picrotoxia in dilute sulphuric acid, for the strong acid chars and destroys it. The solution crystallises on cooling. The sulphate of picrotoxia dissolves in 120 times its weight of boiling water. The solution gradually lets fall the salt in fine silky filaments disposed in bundles, and possessed of great beauty.

Nitrate of picrotoxia. Nitric acid, of the specific gravity 1.38, diluted with twice its weight of water, dissolves, when assisted by heat, the fourth of its weight of picrotoxia. When this solution is evaporated to one-half, it becomes viscid, and on cooling is converted into a transparent mass, similar to a solution of gum-arabic. In this state the nitrate of picrotoxia is acid, and exceedingly bitter.

Muriate of picrotoxia. Muriatic acid, of the specific gravity 1.145, has little action on picrotoxia. It dissolves it when assisted by heat, but does not become entirely saturated. Five parts of this acid, diluted with three times its weight of water, dissolve about one part of picrotoxia at a strong boiling temperature. The liquor, on cooling, is converted into a greyish crystalline mass, composed of confused crystals. When these crystals are well washed, they are almost destitute of taste, and feel elastic under the teeth.

Acetate of picrotoxia. Acetic acid dissolves picrotoxia very well, and may be nearly saturated with it by the assistance of a boiling heat. On cooling, the acetate precipitates in well-defined prismatic needles. This acetate is soluble in 50 times its weight of boiling water.

MENORRHA'GIA. (From μηνια, the menses, and ρηγνυμι, to break out.) *Hæmorrhagia uterina*. Flooding. An immoderate flow of the menses, or uterine hæmorrhage. A genus of diseases in the class *Pyrexiæ*, and order *Hæmorrhagiæ*, of Cullen, characterised by pains in the back, loins, and belly, similar to those of labour, attended with a preternatural flux of blood from the vagina, or a discharge of menses, more copious than natural. He distinguishes six species:—

1. *Menorrhagia rubra*; bloody, from women neither with child nor in child-birth.

2. *Menorrhagia alba*, serous; the fluor albus. See *Leucorrhœa*.

3. *Menorrhagia vitorium*, from some local disease.

4. *Menorrhagia lochialis*, from women after delivery. See *Lochia*.

5. *Menorrhagia abortus*. See *Abortion*.

6. *Menorrhagia nabothi*, when there is a serous discharge from the vagina in pregnant women.

This disease seldom occurs before the age of puberty, and is often an attendant on pregnancy. It is in general a very dangerous disease, more particularly if it occur at the latter period, as it is then often so rapid and violent as to destroy the female in a very short time, where proper means are not soon adopted. Abortions often give rise to floodings, and at any period of pregnancy, but more usually before the fifth month than at any other time. Moles, in consequence of an imperfect conception becoming detached, often give rise to a considerable degree of hæmorrhage.

The causes which most frequently give rise to floodings, are violent exertions of strength, sudden surprises and frights, violent fits of passion, great uneasiness of mind, uncommon longings during pregnancy, over fulness of blood, profuse evacuations, general weakness of the system, external injuries, as blows and bruises, and the death of the child, in consequence of which the placenta becomes partially or wholly detached from the uterus, leaving the mouths of the vessels of the latter, which anastomosed with those of the former, perfectly open. It is necessary to distinguish between an approaching miscarriage and a common flooding, which may be readily done by inquiring whether or not the hæmorrhage has proceeded from any evident cause, and whether it flows gently, or is accompanied with unusual pains. The former usually arises from some fright, surprise, or accident, and does not flow gently and regularly; but bursts out of a sudden, and again stops all at once, and also is attended with severe pains in the back and the bottom of the belly; whereas the latter is marked with no such occurrence. The further a woman is advanced in pregnancy, the greater will be the danger if floodings take place, as the mouths of the vessels are much enlarged during the last stage of pregnancy, and of course a quantity will be discharged in a short time.

The treatment must differ according to the particular causes of the disease, and according to the different states of constitution under which it occurs. The hæmorrhage is more frequently of the active kind, and requires the antiphlogistic plan to be strictly enforced, especially obviating the accumulation of heat in every way, giving cold acidulated drink, and using cold local applications; the patient must remain quiet in the horizontal posture; the diet be of the lightest and least stimulant description; and the bowels kept freely open by cooling laxatives, as the neutral salts, &c. It may be sometimes advisable in robust, plethoric females, particularly in the pregnant state, to take blood at an early period, especially where there is much pain, with a hard pulse; digitalis and antimonials in nauseating doses would also be proper under such circumstances. But where the discharge is rather of a passive character, tonic and astringent medicines ought to be given: rest and the horizontal position are equally necessary, costiveness must be obviated, and cold astringent applications may be materially useful, or the escape of the blood may be prevented mechanically. In alarming cases, perhaps, the most powerful internal remedy is the superacetate of lead, combined with opium; which latter is often indicated by the irritable state of the patient. A nourishing diet, with gentle exercise in a carriage, and the prudent use of the cold bath, may contribute to restore the patient, when the discharge has subsided.

Me'nsa. The second lobe of the liver was so called by the ancients.

ME'NSES. (From *mensis*, a month.) See *Menstruation*.

Menses, immoderate flow of the. See *Menorrhagia.*

Menses, interruption of. See *Amenorrhœa.*

Menses, retention of. See *Amenorrhœa.*

Mensis philosophicus. A philosophical, or chemical month. According to some, it is three days and nights; others say it is ten; and there are who reckon it to be thirty or forty days.

MENSTRUATION. (*Menstruatio;* from *menses.*) From the uterus of every healthy woman who is not pregnant, or who does not give suck, there is a discharge of a red fluid, at certain periods, from the time of puberty to the approach of old age; and from the periods or returns of this discharge being monthly, it is called *Menstruation*. There are several exceptions to this definition. It is said that some women never menstruate; some menstruate while they continue to give suck; and others are said to menstruate during pregnancy; some are said to menstruate in early infancy, and others in old age; but such discharges, Dr. Denman is of opinion, may, with more propriety, be called morbid, or symptomatic; and certainly the definition is generally true.

At whatever time of life this discharge comes on, a woman is said to be at puberty: though of this state it is a consequence, and not a cause. The early or late appearance of the menses may depend upon the climate, the constitution, the delicacy or hardness of living, and upon the manners of those with whom young women converse. In Greece, and other hot countries, girls begin to menstruate at eight, nine, and ten years of age, but, advancing to the northern climates, there is a gradual protraction of the time till we come to Lapland, where women do not menstruate till they arrive at maturer age, and then in small quantities, at long intervals, and sometimes only in the summer. But, if they do not menstruate according to the genius of the country, it is said they suffer equal inconveniences as in warmer climates, where the quantity discharged is much greater, and the periods shorter. In this country, girls begin to menstruate from the fourteenth to the eighteenth year of their age, and sometimes at a later period, without any signs of disease; but if they are luxuriously educated, sleeping upon down beds, and sitting in hot rooms, menstruation usually commences at a more early period.

Many changes in the constitution and appearance of women are produced at the time of their first beginning to menstruate. Their complexion is improved, their countenance is more expressive and animated, their attitudes graceful, and their conversation more intelligent and agreeable; the tone of their voice becomes more harmonious, their whole frame, but particularly their breasts, are expanded and enlarged, and their minds are no longer engaged in childish pursuits and amusements.

Some girls begin to menstruate without any preceding indisposition; but there are generally appearances or symptoms which indicate the change which is about to take place. These are usually more severe at the first than in the succeeding periods; and they are similar to those produced by uterine irritation from other causes, as pains in the back and inferior extremities, complaints of the viscera, with various hysteric and nervous affections. These commence with the first disposition to menstruate, and continue till the discharge comes on, when they abate, or disappear, returning however with considerable violence in some women, at every period during life. The quantity of fluid discharged at each evacuation, depends upon the climate, constitution, and manner of living; but it varies in different women in the same climate, or in the same women at different periods; in this country it amounts to about five or six ounces.

There is also a great difference in the time required for the completion of each period of menstruation. In some women the discharge returns precisely to a day, or an hour, and in others there is a variation of several days, without inconvenience. In some it is finished in a few hours, and in others it continues from one to ten days; but the intermediate time, from three to six days, is most usual.

There has been an opinion, probably derived from the Jewish legislature, afterwards adopted by the Arabian physicians, and credited in other countries, that the menstruous blood possessed some peculiar malignant properties. The severe regulations which have been made in some countries for the conduct of women, at the time of menstruation;—the expression used, Isaiah, chap. xxx. and in Ezekiel:—the disposal of the blood discharged, or of any thing contaminated with it:—the complaints of women attributed to its retention:—and the effects enumerated by grave writers, indicate the most dreadful apprehensions of its baneful influence. Under peculiar circumstances of health, or states of the uterus, or in hot climates, if the evacuation be slowly made, the menstruous blood may become more acrimonious or offensive than the common mass, or any other secretion from it; but in this country and age no malignity is suspected, the menstruous woman mixes in society as at all other times, and there is no reason for thinking otherwise than that this discharge is of the most inoffensive nature.

At the approach of old age, women cease to menstruate; but the time of cessation is commonly regulated by the original early or late appearance of the menses. With those who began to menstruate at ten or twelve years of age, the discharge will often cease before they arrive at forty; but if the first appearance was protracted to sixteen or eighteen years of age, independently of disease, such women may continue to menstruate till they have passed the fiftieth, or even approach the sixtieth year of their age. But the most frequent time of the cessation of the menses in this country, is between the forty-fourth and forty-eighth year; after which women never bear children. By this constitutional regulation of the menses, the propagation of the species is in every country confined to the most vigorous part of life; and had it been otherwise, children might have become parents, and old women might have had children when they were unable to supply them with proper or sufficient nourishment. See *Catamenia*.

ME'NSTRUUM. Solvent. All liquors are so called which are used as dissolvents, or to extract the virtues of ingredients by infusion, decoction, &c. The principal *menstrua* made use of in *Pharmacy*, are water, vinous spirits, oils, acid, and alkaline liquors. Water is the *menstruum* of all salts, of vegetable gums, and of animal jellies. Of the first it dissolves only a determinate quantity, though of one kind of salt more than of another; and being thus saturated, leaves any additional quantity of the same salt untouched. It is never saturated with the two latter, but unites readily with any proportion of them, forming, with different quantities, liquors of different consistencies. It takes up likewise, when assisted by trituration, the vegetable gummy resins, as ammoniacum and myrrh; the solutions of which, though imperfect, that is, not transparent, but turbid and of a milky hue, are nevertheless applicable to valuable purposes in medicine. Rectified spirit of wine is the *menstruum* of the essential oils and resins of vegetables; of the pure distilled oils of animals, and of soaps, though it does not act upon the expressed oil, and fixed alkaline salt, of which soap is composed. Hence, if soap contains any superfluous quantity of either the oil or salt, it may, by means of this *menstruum*, be excellently purified therefrom. It dissolves, by the assistance of heat, volatile alkaline salts, and more readily the neutral ones, composed either of fixed alkali and the acetic acid, as the sal diureticus, or of volatile alkali and the nitric acid. Oils dissolve vegetable resins and balsams, wax, animal fats, mineral bitumens, sulphur, and certain metallic substances, particularly lead. The expressed oils are, for most of these bodies, more powerful *menstrua* than those obtained by distillation; as the former are more capable of sustaining, without injury, a strong heat, which is, in most cases, necessary to enable them to act. All acids dissolve alkaline salts, alkaline earths, and metallic substances. The different acids differ greatly in their action upon these last: one dissolving some particular metals, and another others. The vegetable acids dissolve a considerable quantity of zinc, iron, copper, and tin; and extract so much from the metallic part of antimony as to become powerfully emetic: they likewise dissolve lead, if previously calcined by fire; but more copiously if corroded by their steam. The muriatic acid dissolves zinc, iron, and copper; and though it scarcely acts on any other metallic substance in the common way of making solutions, it may nevertheless be artfully combined with them all. The corrosive sublimate and antimonial caustic of the shops, are combinations of it with the oxides of mercury and antimony, effected by applying the acid in the form of fume, to the subjects at the same time strongly heated. The nitric acid is the common *menstruum* of all metallic substances, except gold and antimony, which are soluble only in a mixture of the nitric and muriatic. The sulphuric acid easily dissolves zinc, iron, and copper; and may be made to corrode, or imperfectly dissolve most of the other metals. Alkaline lixivia dissolve oils, resinous substances, and sulphur. Their power is greatly promoted by the addition of quick lime, instances of which occur in the preparation of soap and in the common caustic. Thus assisted, they reduce the flesh, bones, and other solid parts of animals, into a gelatinous matter. Solutions made in water and spirit of wine, possess the virtue of the body dissolved; whilst oils generally sheathe its activity, and acids and alkalies vary its quality. Hence watery and spirituous liquors are the proper *menstrua* of the native virtues of vegetable and animal matters. Most of the foregoing solutions are easily effected, by pouring the *menstruum* on the body to be dissolved, and suffering them to stand together for some time, exposed to a suitable warmth. A strong heat is generally requisite to enable oils and alkaline liquors to perform their office; nor will acids act on some metallic bodies without its assistance. The action of watery and spirituous *menstrua* is likewise expedited by a moderate heat, though the quantity which they afterwards keep dissolved, is not, as some suppose, by this means increased. All that heat occasions these to take up, more than they would do in a longer time in the cold, will, when the heat ceases, subside again. The action of acids on the bodies which they dissolve, is generally accompanied with heat, effervescence, and a copious discharge of fumes. The fumes which arise during the dissolution of some metals, in the sulphuric acid, prove inflammable; hence, in the preparation of the artificial vitriols of iron and zinc, the operator ought to be careful, especially where the solution is made in a narrow-mouthed vessel, lest, by the imprudent approach of a candle, the exhaling vapour be set on fire. There is another species of solution in which the moisture of air is the *menstruum*. Fixed alkaline salts, and those of the neutral kind, composed of alkaline salts and certain vegetable acids, or of alkaline earths, and any acid except the sulphuric; and some metallic salts on being exposed for some time to a moist air, gradually attract its humidity, and at length become liquid. Some substances, not dissoluble in water in its grosser form, as the butter of antimony, are easily liquified by this slow action of the aerial moisture. This process is termed *Deliquation*. The cause of solution assigned by some naturalists, namely, the admission of the fine particles of one body into the pores of another, whose figure fits them for their reception, is not just, or adequate, but hypothetical and ill-presumed; since it is found that some bodies will dissolve their own quantity of others, as water does of Epsom salt, alkohol of essential oils, mercury of metals, one metal of another, &c. whereas the sum of the pores or vacuities of every body must be necessarily less than the body itself, and consequently those pores cannot receive a quantity of matter equal to the body wherein they reside.

How a *menstruum* can suspend bodies much heavier than itself, which very often happens, may be conceived by considering, that the parts of no fluids can be so easily separated, but they will a little resist or retard the descent of any heavy bodies through them; and that this resistance is, *cæteris paribus*, still proportional to the surface of the descending bodies. But the surfaces of bodies do by no means increase or decrease in the same proportion as their solidities do: for the solidity increases as the cube, but the surface only as the square of the diameter; wherefore it is plain, very small bodies will have much larger surfaces, in proportion to their solid contents, than larger bodies will, and consequently, when grown exceeding small, may easily be buoyed up in the liquor.

MENTA'GRA. (From *mentum*, the chin, and *αγρα*, a prey.) An eruption about the chin, forming a tenacious crust, like that on scald heads.

ME'NTHA. (From *Minthe*, the harlot who was changed into this herb.) *Hedyosmus* of the Greeks. The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Gymnospermia*. Mint.

Mentha aquatica. *Menthastrum*; *Sisymbrium menthrastrum*; *Mentha rotundifolia palustris*. Water-mint. This plant is frequent in moist meadows, marshes, and on the banks of rivers. It is less agreeable than the spear-mint, and in taste bitterer and more pungent. It may be used with the same intentions as the spearmint, to which, however, it is much inferior.

Mentha cataria. See *Nepeta cataria*.

Mentha cervina. The systematic name of the hart's penny-royal. *Pulegium cervinum*. This plant possesses the virtues of penny-royal in a very great degree; but is remarkably unpleasant. It is seldom employed but by the country people, who substitute it for penny-royal.

Mentha crispa. *Colymbifera minor*; *Achillea ageratum*. This species of mentha has a strong and fragrant smell, its taste is warm, aromatic, and slightly bitter. In flatulence of the primæ, viæ, hypochondriacal and hysterical affections, it is given with advantage.

Mentha piperita. The systematic and pharmacopœial name of peppermint. *Mentha piperitis*; *Mentha—floribus capitatis, foliis ovatis petiolatis, staminibus corolla brevioribus*, of Linnæus. The spontaneous growth of this plant is said to be peculiar to Britain. It has a more penetrating smell than any of the other mints; a strong pungent taste, glowing like pepper, sinking, as it were, into the tongue, and followed by a sense of coolness. The stomachic, antispasmodic, and carminative properties of peppermint, render it useful in flatulent colics, hysterical affections, retchings, and other dyspeptic symptoms, acting as a cordial, and often producing an immediate relief. Its officinal preparations are an essential oil, a simple water, and a spirit.

Mentha piperitis. See *Mentha piperita*.

Mentha pulegium. The systematic name of the penny-royal. *Pulegium*; *Pulegium regale*; *Pulegium latifolium glechon*. Pudding-grass. *Mentha—floribus verticillatis, foliis ovatis obtusis subcrenatis, caulibus subteretibus repentibus*, of Linnæus. This plant is considered as a carminative, stomachic, and emmenagogue; and is in very common use in hysterical disorders. The officinal preparations of penny-royal are, a simple water, a spirit, and an essential oil.

Mentha saracenica. See *Tanacetum balsamita*.

Mentha sativa. See *Mentha viridis*.

Mentha spicata. See *Mentha viridis*.

Mentha viridis. Spear-mint. Called also *Mentha vulgaris*; *Mentha spicata*; *Mentha:—spicis oblongis, foliis lanceolatis nudis serratis sessilibus, staminibus corolla longioribus*, of Linnæus. This plant grows wild in many parts of England. It is not so warm to the taste as peppermint, but has a more agreeable flavour, and is therefore preferred for culinary purposes. Its medicinal qualities are similar to those of peppermint; but the different preparations of the former, though more pleasant, are, perhaps, less efficacious. The officinal preparations of spearmint are an essential oil, a conserve, a simple water, and a spirit.

Mentha'strum. (Diminutive of *mentha*.) See *Mentha aquatica*.

Me'nti levator. See *Levator labii inferioris*.

ME'NTULA. (From *matah*, a staff, Heb.) The penis.

Mentula'gra. (From *mentula*, the penis, and *αγρα*, a prey.) A disorder of the penis, induced by a contraction of the erectores musculi, and causing impotence.

MENYA'NTHES. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia*.

Menyanthes trifoliata. The systematic name of the buck-bean. *Trifolium paludosum*; *Trifolium aquaticum*; *Trifolium fibrinum*; *Menyanthes*. Water trefoil, or buck-bean. *Menyanthes—foliis ternatis*, of Linnæus. The whole plant is so extremely bitter, that in some countries it is used as a substitute for hops, in the preparation of malt liquor. It is sometimes employed in country places as an active eccoprotic bitter in hydropic and rheumatic affections. Cases are related of its good effects in some cutaneous diseases of the herpatic and seemingly cancerous kind.

MEPHITIC. Having a disagreeable noxious smell or vapour.

Mephitic acid. The carbonic acid.

Mephitic air. See *Nitrogen*.

MEPHI'TIS. (From *mephuhith*, a blast, Syr.) A poisonous exhalation.

MERCURIALI, Girolamo, was born at

Torli, in Romagna, in 1530. After taking the requisite degree, he settled as a physician in his native town; and was delegated, at the age of 32, on some public business to Pope Pius IV. at Rome. He evinced so much talent on this occasion, that he was particularly invited to remain there; which he accepted, chiefly as it enabled him to pursue his favourite studies to more advantage. He produced, in 1569, a learned and elegant work, "De Arte Gymnastica," which was many times reprinted; and the reputation of this procured him the appointment to the first medical chair at Padua. In 1573, he was called to Vienna to attend the emperor Maximilian II., and was so successful, that he returned loaded with valuable presents, and honoured with the dignities of a knight and count palatine. In 1587, he removed to Bologna, which is ascribed to a degree of self-accusation, in consequence of an error of judgment, into which he had been led, in pronouncing a disease, about which he was consulted at Venice, not contagious, whence much mischief had arisen. His reputation, however, does not appear to have materially suffered from this; and he was invited, in 1599, by the grand duke of Tuscany, to Pisa; but shortly after, a severe calculous affection prevented the execution of his duties, and he retired to his native place, where his death happened in 1606. He was a voluminous writer, and, among many other publications, edited a classified collection of the works of Hippocrates, with a learned commentary; but he was too much bigoted to ancient authority and hypothesis. He wrote on the diseases of the skin, those peculiar to women and children, on poisons, and several other subjects.

MERCURIA'LIS. (From *Mercurius*, its discoverer.

1. The name of a genus of plants in the Linnæan system. Class, *Diœcia*; Order, *Enneandria*.

2. The pharmacopœial name of the French mercury. See *Mercurialis annua*.

Mercurialis annua. The systematic name of the French mercury. The leaves of this plant have no remarkable smell, and very little taste. It is ranked among the emollient oleraceous herbs, and is said to be gently aperient. Its principal use has been in clysters.

Mercurialis montana. See *Mercurialis perennis*.

Mercurialis perennis. The systematic name of dogs' mercury. *Cynocrambe; Mercurialis montana sylvestris.* A poisonous plant, very common in our hedges. It produces vomiting and purging, and the person then goes to sleep, from which he does not often awake.

Mercurialis sylvestris. See *Mercurialis perennis*.

MERCURIUS. (So called from some supposed relation it bears to the planet of that name.) Mercury. See *Mercury*.

Mercurius acetatus. See *Hydrargyrus acetatus*.

Mercurius alkalizatus. See *Hydrargyrum cum creta*.

Mercurius calcinatus. See *Hydrargyri oxydum rubrum*.

Mercurius chemicorum. Quicksilver.

Mercurius cinnabarinus. See *Sulphuretum hydrargyri rubrum*.

Mercurius corrosivus. See *Hydrargyri oxymurias*.

Mercurius corrosivus ruber. See *Hydrargyri nitrico-oxydum*.

Mercurius corrosivus sublimatus. See *Hydrargyri oxymurias*.

Mercurius dulcis sublimatus. See *Hydrargyri submurias*.

Mercurius emeticus flavus. See *Hydrargyrus vitriolatus*.

Mercurius mortis. See *Mercurius vitæ*.

Mercurius præcipitatus albus. See *Hydrargyrum præcipitatum album*.

Mercurius præcipitatus dulcis. See *Hydrargyri submurias*.

Mercurius præcipitatus ruber. See *Hydrargyri nitroco-oxydum*.

Mercurius vitæ. See *Algaroth*.

MERCURY. *Hydrargyrum; Hydrargyrus; Mercurius.* A metal found in five different states in nature. 1. Native, (*native mercury*,) adhering in small globules to the surface of cinnabar ores, or scattered through the crevices, or over the surfaces of different kinds of stones. 2. It is found united to silver, in the ore called *amalgam of silver*, or *native amalgam of silver*. This ore exhibits thin places, or grains; it sometimes crystallises in cubes, parallelopipeda, or pyramids. Its colour is of a silver white, or grey; its lustre is considerably metallic. 3. Combined with sulphur, it constitutes *native cinnabar*, or sulphuret of mercury. This ore is the most common. It is frequently found in veins, and sometimes crystallised in tetrahedra, or three-sided pyramids. Its colour is red. Its streak metallic. 4. Mercury oxidised, and united either to muriatic or sulphuric acid, forms the ore called *horn quicksilver*, or corneous mercury. These ores are, in general, semi-transparent, of a grey or white colour, sometimes crystallised, but more frequently in grains. 5. United to oxygen, it constitutes the ore called *native oxide of mercury*. Mercurial ores particularly abound in Spain, Hungary, China, and South America.

Properties.—Mercury, or quicksilver, is the only one of the metals that remains fluid at the ordinary temperature of the atmosphere, but when its temperature is reduced to—40 degrees below 0 on Fahrenheit's thermometer; it assumes a solid form. This is is a degree of cold, however, that only occurs in high northern latitudes, and, in our climate, mercury cannot be exhibited in a solid state, but by means of artificial cold. When rendered solid, it possesses both ductility and malleability. It crystallises in octahedra, and contracts strongly during congelation. It is divisible into very small globules. It presents a convex appearance in vessels to which it has little attraction, but is concave in those to which it more strongly adheres. It becomes electric and phosphorescent by rubbing upon glass, and by agitation in a vacuum. It is a very good conductor of caloric, of electricity, and of galvanism. The specific gravity of mercury is 13.563. Although fluid, its opacity is equal to that of any other metal, and its surface, when clean, has considerable lustre. Its colour is white, similar to silver. Exposed to the temperature of somewhat above 600° Fahr. it is volatilised. When agitated in the air, especially in contact with viscous fluids, it becomes converted into a black oxide. At a temperature nearly the same as that at which it boils, it absorbs about 14 or 16 per cent. of oxygen, and then becomes changed into a red crystallisable oxide, which is spontaneously reducible by light and caloric at a higher temperature. The greater number of the acids act upon mercury, or are at least capable of combining with its oxides. It combines with sulphur by trituration, but more intimately by heat. It is acted on by the alkaline sulphurets. It combines with many of the metals; these compounds are brittle, or soft, when the mercury is in large proportion.

There is a slight union between mercury and phosphorus. It does not unite with carbon, or the earths.

Method of obtaining Mercury.—Mercury may be obtained pure by decomposing cinnabar, by means of iron filings. For that purpose, take two parts of red sulphuret of mercury (cinnabar,) reduce it to powder, and mix it with one of iron filings, put the mixture into a stone retort, direct the neck of it into a bottle, or receiver, filled with water, and apply heat. The mercury will then be obtained in a state of purity.

In this process, the sulphuret of mercury, which consists of sulphur and mercury, is heated in contact with iron, the sulphur quits the mercury and unites to the iron, and the mercury becomes disengaged; the residue in the retort is a sulphuret of iron.

Mercury is a very useful article both in the cure of diseases and the arts. There is scarcely a disease against which some of its preparations are not exhibited; and over the venereal disease it possesses a specific power. It is considered to have first gained repute in curing this disease, from the good effects it produced in eruptive diseases. In the times immediately following the venereal disease, practitioners only attempted to employ this remedy with timorous caution, so that, of several of their formulæ, mercury scarcely composed a fourth part, and few cures were effected. On the other hand, empirics who noticed the little efficacy of these small doses, ran into the opposite extreme, and exhibited mercury in such large quantities, and with such little care, that most of their patients became suddenly attacked with the most violent salivations, attended with dangerous consequences. From these two very opposite modes of practice, there originated such uncertainty respecting what could be expected from mercury, and such fears of the consequences which might result from its employment, that every plan was eagerly adopted which offered the least chance of cure without having recourse to this mineral. A medicine, however, so powerful, and whose salutary effects were seen by attentive practitioners, amid all its inconveniences, could not sink into oblivion. After efforts had been made to discover a substitute for it, and it was seen how little confidence those means deserved on which the highest praises had been lavished, the attempts to discover its utility were renewed. A medium was pursued, between the too timid methods of those physicians who had first administered it, and the inconsiderate boldness of the empirics. Thus the causes from which both parties failed were avoided; the character of the medicine was revived in a more durable way, and from this period its reputation has always been maintained.

It was about this epoch that mercury began to be internally given: hitherto it had only been externally employed, which was done in three manners. The first, was in the form of liniment, or ointment; the second, as a plaster; and the third, as a fumigation. Of the three methods just described, only the first is at present much in use, and even this is very much altered. Mercurial plasters are now only used as topical discutient applications to tumours and indurations. Fumigations, as anciently managed, were liable to many objections, particularly from its not being possible to regulate the quantity of mercury to be used, and from the effect of the vapour on the organs of respiration frequently occasioning trembling, palsies, &c. Frictions with ointment have always been regarded as the most efficacious mode of administering mercury.

Mercury is carried into the constitution in the same way as other substances, either by being absorbed from the surface of the body, or that of the alimentary canal. It cannot, however, in all cases, be taken into the constitution in both ways, for sometimes the absorbents of the skin will not readily receive it; at least no effect is produced, either on the disease or constitution, from this mode of application. On the other hand, the internal absorbents will, sometimes, not take up the medicine, or, at least, no effect is produced either on the disease or constitution. In many persons, the bowels can hardly bear mercury at all; and it should then be given in the mildest form possible, conjoined with such medicines as will lessen or correct its violent effects, although not its specific ones, on the constitution. When mercury can be thrown into the constitution with propriety, by the external method, it is preferable to the internal plan; because the skin is not nearly so essential to life as the stomach, and is therefore in itself capable of bearing much more than the stomach. The constitution is also less injured. Many courses of mercury would kill the patient if the medicine were only given internally, because it proves hurtful to the stomach and intestines, when given in any form, or joined with the greatest correctors.

Mercury has two effects; one as a stimulus on the constitution and particular parts, the other as a specific on a diseased action of the whole body, or of parts. The latter action can only be computed by the disease disappearing.

In giving mercury in the venereal disease, the first attention should be to the quantity, and its visible effects in a given time; which, when brought to a proper pitch are only to be kept up, and the decline of the disease to be watched; for by this we judge of the invisible or specific effects of the medicine, and know what variation in the quantity may be necessary. The visible effects of mercury affect either the whole constitution, or some parts capable of secretion. In the first, it produces universal irritability, making it more susceptible of all impressions. It quickens the pulse, increases its hardness, and occasions a kind of temporary fever. In some constitutions it operates like a poison. In some it produces a hectic fever; but such effects commonly diminish on the patient becoming accustomed to the medicine.

Mercury often produces pains like those of rheumatism, and nodes of a scrophulous nature. The quantity of mercury to be thrown in for the cure of any venereal complaint, must be proportioned to the violence of the disease. A small quantity used quickly, will have equal effects to those of a large one employed slowly; but if these effects are merely local, that is, upon the glands of the mouth, the constitution at large not being equally stimulated, the effects upon the diseased parts must be less, which may be known by the local disease not giving way in proportion to the effects of mercury on some particular part. If it be given in very small quantities, and increased gradually, so as to steal insensibly on the constitution, a vast quantity at a time may at length be thrown in, without any visible effects at all.

The constitution, or parts, are more susceptible of mercury at first than afterwards.

Mercury occasionally attacks the bowels, and causes violent purging, even of blood. This effect is remedied by intermitting the use of the medicine, and exhibiting opium. At other times, it is suddenly determined to the mouth, and produces inflammation, ulceration, and an excessive flow of saliva. To obtain relief in this circumstance, purgatives, nitre, sulphur, gum-arabic, lime-water, camphor, bark, sulphuret of potassa, blisters, &c. have been advised. Pearson, however, does not place much confidence in the efficacy of such means; and, the mercury being discontinued for a time, he recommends the patient to be freely exposed to cold air, with the occasional use of cathartics, mineral acids, Peruvian bark, and the assiduous application of astringent gargles. "The most material objection (says Pearson) which I foresee against the method of treatment I have recommended, is the hazard to which the patient will be exposed of having the saliva suddenly checked, and of suffering some other disease in consequence of it.

The hasty suppression of a ptyalism may be followed by serious inconveniences, as violent pains, vomiting, and general convulsions.

Cold liquids taken into the stomach, or exposure of the body to the cold air, must be guarded against during a course of mercury. Should a suppression of the ptyalism take place, from any act of indiscretion, a quick introduction of mercury should be had recourse to, with the occasional use of the warm bath.

Mercury, when it falls on the mouth, sometimes produces inflammation, which now and then terminates in mortification. The ordinary operation of mercury does not permanently injure the constitution; but, occasionally, the impairment is very material; mercury may even produce local diseases, and retard the cure of chancres, buboes, and certain effects of the lues venerea, after the poison has been destroyed. Occasionally mercury acts on the system as a poison, quite unconnected with its agency as a remedy, and neither proportionate to the inflammation of the mouth nor actual quantity of the mineral absorbed. Pearson has termed this morbid state of the system erethismus; it is characterised by great depression of strength, a sense of anxiety about the præcordia, irregular action of the heart, frequent sighing, trembling, a small, quick, and sometimes intermitting pulse, occasional vomiting, a pale contracted countenance, a sense of coldness; but the tongue is seldom furred, and neither the natural or vital functions are much disturbed. When this effect of mercury takes place, the use of mercury should be discontinued, whatever may be the stage, extent, or violence of the venereal disease. The patient should be exposed to a dry and cool air, in such a way as not to give fatigue; in this way, the patient will often recover in ten or fourteen days. In the early stage, the erethismus may often be averted by leaving off the mercury and giving camphor mixture with volatile alkali. Occasionally, the use of mercury brings on a peculiar eruption, which has received the names of mercurial rash, eczema mercuriale, lepra mercurialis, mercurial disease, and erythema mercuriale.

In order that mercury should act on the human body, it is necessary that it should be oxidised, or combined with an acid. The mercury contained in the unguentum hydrargyri, is an oxide. This, however, is the most simple and least combined form of all its preparations, and hence, (says Mr. S. Cooper,) it not only operates with more mildness on the system, but with more specific effect on the disease. Various salts of mercury operate more quickly when given internally than mercurial frictions; but few practitioners of the present day confide in the internal use of mercury alone; particularly when the venereal virus has produced effects in consequence of absorption. Rubbing in mercurial ointment is the mode of affecting the system with mercury in the present day; and, as a substitute for this mode of applying mercury, Mr. Abernethy recommends the mercurial fumigation, where the patient has not strength to rub in ointment, and whose bowels will not bear the internal exhibition of it.

The preparations of mercury now in use are,

1. Nitrico-oxydum hydrargyri.
2. Oxydum hydrargyri cinereum.
3. Oxydum hydrargyri rubrum.
4. Oxy-murias hydrargyri.
5. Submurias hydrargyri.
6. Sulphuretum hydrargyri rubrum et nigrum.
7. Hydrargyrum cum creta.
8. Hydrargyrum precipitatum album.
9. Hydrargyrum purificatum.

Mercury, dog's. See *Mercurialis.*

Mercury, English. See *Chenopodium bonus henricus.*

Mercury, French. See *Mercurialis.*

Meroba'lneum. (From μερος, a part, and βαλανειον, a bath.) A partial bath.

MEROCE'LE. (From μερος, the thigh, and κηλη, a tumour.) A femoral hernia. See *Hernia.*

Me'ron. Μηρος. The thigh.

MERRET, Christopher, was born at Winchcombe in 1614. After graduating at Oxford, he settled in London, became a fellow of the College of Physicians, and one of the original members of the Philosophical Society, which, after the Restoration, was called the Royal Society. He appears to have had a considerable practice, and reached his 81st year. His first publication was a Collection of Acts of Parliament, &c. in proof of the exclusive Rights of the College, printed in 1660; which afforded the basis of Dr. Goodall's history: this was followed nine years after by "A short View of the Frauds of Apothecaries," which involved him in much controversy. He published also a Catalogue of the Natural Productions of this Island, of which the botanical part is best executed; and he communicated several papers to the Royal Society.

ME'RUS. Applied to several things in the same sense, as genuine or unadulterated; as *merum vinum*, neat wine.

MERY, John, was born at Vatau, in France, in 1645. His father being a surgeon, he determined upon the same profession, and went accordingly to the Hôtel Dieu at Paris, where he studied with extraordinary ardour, even passing the night in dissection in his bed-room. In 1681 he was appointed to the office of queen's surgeon; and two years after, surgeon-major to the invalids. Soon after this he was chosen to attend the Queen of Portugal, who died, however, before his arrival; and he refused very advantageous offers to detain him at that, as well as the Spanish court. He was now received into the Academy of Sciences, and shortly after sent on a secret journey to England; then chosen to attend upon the Duke of Burgundy, who was a child. But these occupations were irksome to him, and he even shunned private practice, and general society, devoting himself to the duties of the hospital of Invalids, and to the dissecting-room. In 1700 he was appointed first surgeon to the Hôtel Dieu, which gratified his utmost ambition; and he declined repeated solicitations to give lectures there on anatomy. He procured, however, the erection of a theatre for the students, where they might have more regular instruction. It was a great part of the labour of his life to form an anatomical museum, yet he did not estimate these researches too highly, and was very slow in framing, or in receiving, new theories concerning the animal economy. About the age of 75, he suddenly lost the use of his legs, after which his health declined, and he died in 1722. Besides many valuable communications to the Academy of Sciences, he published a description of the ear; Observations on Frère Jacques' Method of Cutting for the Stone, the general principle of which he approved; a tract on the Fœtal Circulation, controverting the received opinion, that part of the blood passes from the right to the left ventricle, through the foramen ovale, and even assigning it an opposite course; and physical problems, concerning the connexion of the fœtus with the mother, and its nutrition.

Mesaræ'um. (From μεσος, the middle, and αραια, the belly.) The mesentery.
